It has been admitted in the trade here that a Bosch magneto helped to sell a car; now that the public for the first time is willing to accept other makes of magnetos, it is surprising that British manufacturers are not showing more faith. THERE APPEARS TO BE AN OPENING HERE FOR AMERICAN MANUFACTURERS. FRENCH AND ENGLISH ENGINEERS WITH WHOM I HAVE SPOKEN ADMIT THAT THERE ARE AMERICAN MAGNETOS EQUAL TO ANY PRODUCED IN EUROPE. IN ENGLAND IT IS CONSIDERED THAT THE AMERICAN MAGNETO COMPANIES WILL MEET THE SHORTAGE OF GERMAN-MADE MAGNETOS.

Gasoline Is Plentiful

France and England are experiencing no shortage of gasoline. The average retail price in Paris is only about 1 cent per gallon higher than it was before the outbreak of war. This slight increase is due in all cases to the extra cost of cartage or to the lessened demand. Retailers get a bonus on quantities; private sales not being as brisk as formerly, they are not buying to the same advantage and consequently have to sell at a higher price.

In England the price of gasoline has gone back to normal rates, and there, as in France, there is no possibility of a shortage. The British army on the Continent is importing from England the whole of its gasoline supply and has never experienced the least shortage.

Boillot in Accident—Other Drivers in Service

PARIS, Oct. 1—According to reports from the front, Georges Boillot has been involved in a serious accident while on active service. The French race driver was traveling at high speed, with three staff officers in his car, when he ran off the road at a bend in an attempt to avoid a car coming in the opposite direction. All the occupants of the car were thrown out, two of the officers being rendered unconscious, but their injuries were not of a serious nature. Boillot was uninjured, although his car was so completely wrecked that it had to be abandoned. He resumed service with another car. Although Boillot is attached to the headquarters staff, he is not driving General Joffre. The head of the French army moves about comparatively little; when he does travel it is by automobile with one of his staff officers at the wheel.

Goux Driving Officers

Jules Goux, who went into one of the forts at Belfort on the outbreak of war, has been transferred to the automobile section, and is now driving officers in a Peugeot. Louis Wagner, who finished second for Mercedes in the last French Grand Prix, has not been allowed to enter either the automobile or the aviation section of the French army. He is serving as an artilleryman on the Eastern frontier. The refusal to allow Wagner to serve in the branches in which he has so distinguished himself, is doubtless due to his recent connection with the German firm. Wagner is purely of French origin, and does not even speak a word of German. But in such times as the present the army will not take any risks, and all men who have had recent connections with German firms are put into unimportant posts.

No Names Given

News of motorists at the front is very scarce, no names are mentioned in dispatches, and when men are killed or wounded only their nearest relatives are privately informed. No lists are published in the newspapers or elsewhere. Men writing home are not allowed to state where they are stationed or where they are going to.

Truck Convention Success—300 Delegates Discuss Pertinent Subjects

Service Dealers Should Give Is Leading Subject Considered—Dealers Must Carry Adequate Supply of Parts—Room for Small Vehicles—Tires Ruined by Overspeeding and Overloading—Controlling the Drivers

Get Together

Almost all of the advantages which man possesses above the inferior animals arises from his power of acting in combination with his fellows, and of accomplishing by the united efforts of numbers what could not be accomplished by the detached efforts of individuals.—John Stuart Mill, the Convention Watchword.

DETROIT, MICH., Oct. 10—The 4-day convention of motor truck manufacturers, dealers and owners conducted by the Motor Truck Club of America came to a successful conclusion in this city today, the 300 registered delegates from the truck and accessory industries uniting in declaring the convention a success and hoping for a similar one next year.

The idea of a motor truck convention was started early in the spring, the dominant thought of "get together" being to bring the makers, dealers and owners in this new industry face to face, to get them acquainted and to unite in eliminating the abuses of the industry and solving its problems.

Upwards of fifty different truck makers were represented, the tire makers producing truck tires were on hand, dealers were present from many cities in goodly numbers, there were some owners present and the United States Government sent its official representative to assist in the work and invite the Motor Truck Club to hold its 1915 convention at San Francisco during the exposition.

The Thirty-four Varieties

Extending a program on matters relating to truck operation, manufacture and maintenance over 4 days was a herculean task and not fewer than thirty-four papers were presented covering the gamut entirely. These papers began with the omnipresent topic of service to truck owners, which was handled by both dealers and manufacturers. Tire problems were handled by three representatives of the tire industry who analyzed the evils of overloading and overspeeding, etc.

Two papers were presented on the question of time payments for trucks. Charges for demonstrations in making truck sales; traffic engineering; parts to be carried in stock by dealers; the use of trucks on farms, and a score of other papers pertinent to truckdom were on the calendar and all were discussed at length—in fact there was not time enough to tell the whole story of the truck field, and what are its sins of omission and commission.

All of the sessions at which addresses were made or papers read, and there were six of them, were well attended with the exception of the last one held this morning, the attendance averaging close to the 100 mark. The sentiment was general throughout that there was much to be learned and the time was short. The makers and dealers were intent on the varied subjects from start to finish.

Want to Organize

Many of the makers had made up their minds that if they attended a truck convention they must immediately form some sort of organization for their mutual benefit, and with this object in mind a caucus was held Thursday afternoon which was attended by over a score of truck makers who are not members of any organization. Many favored a national truck organization rather than joining with the present national organization, the National Automobile Chamber of Commerce, which counts in its membership thirty-three truck makers and which has a special committee for commercial vehicle work. A committee was formed to report on the subject. It is not known as yet what course of action this committee will recommend, but it is expected to report back to the different makers represented at the convention within 2 months.

The sentiment was apparent that there has not been enough of the "get together" spirit in the truck field, and that the National Automobile Chamber of Commerce has been devoting more attention to the passenger car industry than to the truck field. Many of the truck makers present expressed a desire that this national body attack the existing evils in the truck field more vigorously and that it take immediate steps to largely increase its membership, receiving into its ranks perhaps thirty or forty truck makers who are at present not counted in its membership. Action of this nature would bring its representation in the truck field up to seventy-five, and the feeling is quite general that there are 100 makers of trucks in America whose names should appear on its roster.

Successful Discussions

It is rarely in the first convention of its kind that such open-hearted discussion followed the reading of many papers; in fact, the truck makers, who had never before met in convention, talked right out from the shoulder with as much parliamentary atmosphere as do the members of the Society of Automobile Engineers, who have been educating themselves in such discussions for several years. Many of the makers had real problems to solve and they came prepared to tell their own secrets, to come direct to the point rather than beat around the bush and return home without getting results.

Invitations were read from the Mayor

of Buffalo and the Chamber of Commerce inviting the truck makers to the Bison City for 1915. Detroit also advanced its claims and special representative J. M. Hill, of San Francisco, advanced the claims of the Pacific Coast for next year. The selection of a place has been left with the Motor Truck Club of America.

The framers of the program for the convention had aimed at featuring those topics that had to do with the merchandising and maintenance of motor trucks rather than matters relating to the manufacture of them and the engineering problems entering into their makeup, and it was this practical aspect of merchandising as well as the bugaboo of service that called for the longest discussions in the convention which has just come to a close.

Service, Spare Parts, Demonstration, Tires, Drivers

Some Topics Discussed at the Motor Truck Convention

Day Defines Service As Stock of Parts and Speed

FAVORS PRESENT 90-DAY WARRANTY

It remained for W. L. Day of the General Motors Truck Co. to fire the opening bomb on service as the truck maker sees it. "We are all wrong in this matter of service," began Mr. Day. "Service should consist in a policy of no free repairs or replacements except under the strict letter of the manufacturer's warranty, no free demonstrations in making sales, no free-service trucks to be loaned to owners when they are having their own trucks repaired or overhauled, yet having ample stocks of repair parts together with adequate facilities for handling them; periodic inspection of the trucks, reports of these inspections to owners and adequate instructions to drivers before the trucks are turned over to their care."

Mr. Day was in favor of the present 90-day warranty of the National Automobile Chamber of Commerce and believed that it should be extended to cover a period of 1 year. In tracing the history of the service problem from its inception down to the present Mr. Day blames competition for the present evils and predicted that a continuation of such competition would lead to eventual failure and bankruptcy.

The Dealers' Viewpoint

J. H. Thompson, a Detroit truck dealer, championed the side of the dealers in this service argument, and began by assailing the present 90-day warranty of the makers as a meaningless document, the only certainty about it being that the buyer could secure perfect parts for imperfect ones, if the imperfections exhibited themselves within the 90-day period. "But," continued Mr. Thompson, "the owner must send the imperfect part back to the factory at his own expense, while his truck stands idle at the expense of business efficiency. Once the part arrives at the factory it remains with the factory to determine whether the part is really defective or not, and if the factory decides to send a new part it is done at the expense of the owner and he must also install it at his own expense, if the dealer will not do so.

"The truck maker should provide in his warranty for the cost of fitting free parts covered by the warranty, because at present the dealer is generally called upon to do this work and he must do it at his own expense. The dealer can only do this providing the discount on the trucks he sells is liberal enough for such a policy. Very often it is necessary for the dealer to provide spare trucks for the use of owners when theirs are being repaired.

"In service the dominant question is not how much should be free but how prompt and effective the service should be. If prompt and efficient service at reasonable charge is given, the purchaser is generally willing to pay the bill."

W. G. Cronkright, president of the Duquesne Motor Truck Co., in speaking of the problem on service to truck owners advocated the establishment of clearing houses for repair parts in different parts of the country, these clearing houses to carry spare parts for perhaps a hundred or more different makes of trucks, and to be conducted in some manner that would be satisfactory to all owners. Such a series of clearing houses would take off the dealer the burden of a heavy stock of repair parts which he must carry, and would simultaneously assure to any truck owner the ability to quickly secure spare parts irrespective of the section of the country in which he lives.

B. A. Gramm, a truck maker, drew a parallel between the motor truck industry and the machine tool industry in so far as service by the manufacturer applies. When machine tools are purchased and installed in your factory the machine-tool maker does not loan you an additional machine that you can use when the one you purchased is being repaired; rather it is up to the manufacturer of trucks to utilize other machines in his factory to do the same work while the other machine is being repaired. In the truck field many owners and dealers also think it necessary to loan a spare truck to the owner while he is having a repair made on his. This

Thompson Analyzes Service From Dealers' Viewpoint

GRAMM OPPOSES FREE SERVICE

is not businesslike, and its parallel cannot be found in the old-established industrial lines. The sooner the truck dealer stops it the sooner will he begin making a legitimate profit out of his business and the sooner will the buyer have reinvigorated confidence in him.

Mr. Pratt, one of the owners present, stated that, as an operator of a small fleet, he had found that the greatest trouble with service was that most users did not apply the same business principles to the use of trucks as they did to their own lines of business. His company started the use of trucks with a $15-a-week shipping clerk in exclusive charge of the vehicles, and the usual failure was encountered. Since that time, however, owing to his own studies into the matter of truck efficiency, the trucks, like all the rest of the machinery of the plant, had been put in the charge of the master mechanic, the drivers being required only to drive, the shipping clerk only to ship, and all being subservient to the master mechanic in respect to the physical aspects of the operation of the rolling stock. He applied the analogy of the railroad roundhouse system to this, pointing out that railroad locomotives were in the care of the master mechanic, and that they were rigidly inspected by special round-house men after each trip, the train dispatcher being required to govern their movements only, and the engineers only to drive them.

W. A. Conant of the Gould Storage Battery Co., was another who stated that the matter of service revolves largely around the question of speed. If the dealer is equipped to offer service and has the necessary parts, he said, the purchaser of the truck is willing to pay for the service. He offered as his opinion that it is prompt attention to the little problems that beset the truck user rather than slower solution of the large ones that brings the greatest satisfaction.

Spare Parts for Dealer—Eliminating the Demonstration

All Dealers Should Carry Adequate Supply of Spare Parts

FACTORY CONSIGNS TO DEALER

M. L. Pulcher of the Federal company discussed the very imporant subject of the amount of spare parts that a motor truck dealer should carry in stock, taking the viewpoint that the quantity of parts carried depended on the size of territory and also the distance of this territory from the factory. Further, the truck factory should cooperate with the dealer to the extent of consigning him parts on a 50-50 basis, that is, the dealer would be required to pay for one-half his stock of parts when same were received, and to pay the factory for the other half when they had been sold, the dealer to give an accounting to the factory each month.

In speaking on the question of list prices of trucks, as published by different makers, Mr. Pulcher said: "There is no standard of lists at the present time. A high list on a certain truck allows your dealer too much margin, and permits him to cut prices, which means that practically all purchasers buy your trucks at a different list. One Chicago purchaser reports that out of 275 trucks not more than three had been purchased at the list price. In view of this we are all wrong as manufacturers in deviating from our list. In nearly every town you will find two or three good truck dealers with up-to-date, clean, business-like salesrooms, and invariably these are the dealers who maintain their lists and secure legitimate profits.

"Every sale a dealer makes at a cut price under loss is a detriment to the maker of that truck. Next to the railroad, the motor truck business should be the largest industry in the country.

"Buyers do not like purchasing at cut prices, and personally I have never entered a store where they cut prices, but I have left feeling that I did not get the goods as low as some other buyer.

"Truck manufacturers can assist dealers in maintaining prices. There is a certain company in the motor truck field which audits the books of its dealers regularly, and by this procedure has brought the truck business up to a higher plane. I have tried to buy a passenger car of this company at a discount, but have not been able. Their policy of sticking to their price is a strong argument in convincing you that their vehicles are worth the price asked for."

In speaking of discounts to be allowed for quantity business in trucks, Mr. Pulcher drew attention to the great differences in the policy of companies at the present time in this work. One maker gives a 50 per cent. discount on large quantities, and another gives 7 to 10 per cent. discount on lots of 100 trucks. Single orders are not quantity business and should not carry discounts. The desirable discounts for quantity business are as follows:

	Discount
Order of 5 trucks.......	5.0 per cent.
Order of 25 trucks......	7.5 " "
Order of 50 and up.....	10.0 " "

The motor truck maker must remember that quantity business means trucks being delivered to many parts of the country, and the maker must realize that his dealers in these different cities will have to give more or less service on such orders. Because of this the manufacturers must retain a certain amount of money out of quantity business for the dealers into whose territory these trucks are delivered.

In selling spare parts they should be listed so that the total parts entering into a truck should not exceed the list price of a truck; in other words, there should not be any effort to get a higher price on spare parts than is legitimate. The dealer should get the same discount on these parts that he receives on the trucks, and an additional discount of 5 per cent. for cash on the 10th of the month. Mr. Pulcher believes that this additional discount is a good method of getting a correct estimate on the dealer and his business methods by the manufacturer.

In speaking of the stock of parts which the dealer should carry on hand, Mr. Pulcher said: "The stock of parts carried by a dealer depends on the number of trucks sold in the district and the distance of this district from the factory. All dealers should carry a good stock of parts, but generally they do not carry enough. The policy of our company is to insist on a dealer carrying a certain value of parts, and we check up his stock periodically to see that this is done. We have divided the entire country into zones, not unlike that of the parcel post service. In general, all parts carried by a dealer should pe purchased outright, but frequently this is impossible because of the amount of money so tied up. To make this possible, we share the burden on a 50-50 basis with the dealer, requiring him to pay the additional 50 per cent. value when the parts are sold. In this connection we will not allow the obligations of the dealer to the factory to exceed $5,000, and for all parts above this he must pay when received."

Free Demonstrations Fail To Sell Trucks in Detroit

DEMONSTRATIONS ARE UNNECESSARY

J. C. Ayres, a Detroit motor truck dealer, in speaking on the subject of demonstrations, and whether they should be free, charged for or made at all, told how after 3 years of experience he had found his business as great at the end of a year in which he had not made any demonstrations, as at the end of a similar period when he had charged for demonstrations. With free demonstrations he only made one sale out of eighty-one demonstrations; when charging for demonstrations he sold to 87 per cent. of those he demonstrated for, and with no demonstrations his sales showed a steady increase.

In analyzing the question of demonstrations Mr. Ayres said: "During 12 months we made free demonstrations and our records show that out of eighty-one free demonstrations we made but one actual sale, in other words eighty of the firms we demonstrated for did not buy from us. Of these eighty concerns only four bought trucks from other makers during the 12 months, so that there were seventy-six concerns that were getting free haulage from the motor truck dealers without even having to make a purchase.

"We next tried a period when we charged for demonstrations on a scale ranging from $8 to $25 per day, according to truck capacity and whether the work was done on city streets or over country roads. At the end of the 14 months we had sold to 87 per cent. of the concerns we made demonstrations for.

"Following this period of charged demonstrations we instituted a regime of no demonstrations and at the end of 10 months the percentage of total business was higher than in any similar period under the regime of either free or charged demonstrations.

Demonstrating Rates

"The usual schedule which should be followed in charging for demonstrations is:

$8.00 per day for a 1,500-pound truck
10.00 per day for a 2,000-pound truck
12.50 per day for a 2-ton truck
15.00 per day for a 3-ton truck
20.00 per day for a 5-ton truck
25.00 per day for a special lumber job or a job with a dump body.

"An increase of $5 per day should be charged whenever the trucks are operated in the country or over unusually hilly roads. There should be an extra charge of 10 per cent for overtime, the above rates of charge being based on a 10-hour day.

"If the concern or individual for whom you demonstrate buys a truck the question is frequently asked, should the dealer rebate to him the cost of the demonstration? He certainly should not. You are delivering the buyer a service, you are delivering his goods, the cost of which is a recognized item in any business. You are showing him the application of motor delivery to his business and he should be willing to pay for it. The demonstration charges should not be rebated; the dealer has already rendered a service, the buyer would have to pay to have these goods delivered if he had not his own teams or the dealer had not done it."

Time payments for motor trucks is a subject that has agitated the truck industry for many moons and two representatives, one of the industry and another from the outside, presented their views on this subject. The consensus of opinion on this pertinent topic is that the periods of payments should be under a year and that there should be a deposit of from 25 to 30 per cent. at the time of purchase.

Too Few Makers Build Small-Motor Vehicles

BIG FIELD FOR UNDER-TON TYPES

"There are 60,000 to 80,000 Ford passenger cars fitted out yearly to perform delivery functions," according to E. S. Foljambe, in his paper on "The Field for Medium Size and Small Trucks." By medium size and small trucks Mr. Foljambe referred to vehicles of 1200 to 2000 pounds capacity.

In further showing the enormous field of possibilities for small trucks, which field he considers neglected by the makers, Mr. Foljambe showed that between 1900 and 1910 the government statistics show an increase of 1,566,000 in the number of horses in use on our farms, or 8.6 per cent. At this rate of increase, and with 19,833,113 horses in 1910, there should now be in use approximately 20,000,000 horses. Mules, burros, and other draft animals have increased during the same period, 11.7 per cent., making the total number now in use 4,247,800, or a total of over 24,000,000. This does not take into consideration the 2,000,000 or more horses in cities. At the same time the average price of the horse has increased from $53 in 1900, to $112 in 1910, and of mules from $64 to $131.

A realization of how little inroad the truck has already made is borne in upon us when we consider the following figures: From 1908 until the present time inclusive, there have been produced in the United States, approximately 180,000 commercial cars; 100,000 to 125,000 of these are probably now in use. On an average, counting all sized vehicles, these do not displace more than three horses each, or a total number of horses displaced of not over 375,000. When this number is compared to the total number of horses and draft animals in use, it is found that commercial cars have in reality displaced less than 1.5 per cent., and even taking into consideration the motor driven farm tractor, the possible field still not covered is fully 98 per cent.

In regard to the weight of average loads in the "delivery" field, there is much ignorance even on the part of the users. Reference again to Interstate Commerce figures may be enlightening. These show that 95 per cent. of all parcel delivery packages handled in this country come under 50 lbs. in weight. Investigation by a New York firm making a specialty of analyzing delivery methods showed the average of all loads for retail distribution to reach the astonishingly low figure of 550 lbs.

The following figures are from a study of the weight of loads made by a large department store of Philadelphia during a rush period. For package delivery this company, and it is not alone, employs a vehicle weighing 4,000 lbs., with a rated capacity of 3,000 lbs. A careful analysis showed the loads to range from 800 lbs. to a maximum of 1,195 lbs., with the vehicle body piled just as full as it could be packed. This body was 9 ft. long, 56 in. wide, and 78 in. high. The total load moved by the motor with the maximum payload on the vehicle was 5,195 lbs., the payload representing but 23 per cent. of this total weight, while the dead load moved is represented by 77 per cent.

A study of one of the largest candy companies of New York City showed the following results, motor driven trucks during the normal period carried as follows: 22.3 per cent. payload, and 77.7 non-paying load; another truck but 18.8 payload, and 81.2 non-paying load; another 24.7 payload, and 75.3 non-paying load, while the horse vehicles showed a payload capacity of 41.8 and 58.2 non-paying load. During a rush period the same cars showed 22.7 per cent., 23.5 per cent., and 29.8 per cent., or an average non-paying load of 74.7 per cent. THE PAYLOAD IS A CONSTANTLY DIMINISHING ONE, WHILE THE NON-PAYING LOAD MUST BE MOVED OVER THE ENTIRE ROUTE. CONCLUSION, IT COSTS TOO MUCH TO DELIVER THE VEHICLE.

The analysis of the ratio of payload to dead load shows that the remedy lies in a reduction in the size and weight of vehicle, more in conformity with the average loads carried and that more frequent trips with these more nearly capacity loads must be made.

The bodies play an important part in the use of the vehicle in its proper field. The Philadelphia firm's experience showed that a body 9 ft. by 56 by 78 in. would not carry more than 1,100 to 1,200 lbs. of the class of goods being handled, and that a smaller capacity vehicle fitted with such a body would be more economical.

Overspeeding and Overloading Cause Tire Turmoil

TIRE COMPANIES SHOW ABUSES

Nearly an entire afternoon was given over to the question of truck tires, and the evils arising from overspeeding and overloading trucks. Representatives of Goodrich, Firestone and Goodyear presented papers on different aspects of the tire situation and a general discussion followed the presentation of these papers.

Trucks Under-tired

Roy Harris, of the Firestone Tire & Rubber Co., presented a paper on "Proper Load Rating of Truck Tires," He traced the development of the movement for oversized tires on passenger vehicles, and its transmission to the truck tire field, and pointed out that it was short-sighted of the maker to under-tire his vehicles, for the owner soon learns that it is poor economy, and has to go to the expense of having his wheels made over in order to fit larger tires. On reordering he remembers this and is apt to avoid a second purchase of an under-tired truck. Large and experienced users appreciate from bitter experience the importance of adequate tiring, and look with disfavor upon the man who tries to sell a truck with skimped tire equipment.

He discussed load distribution, center of gravity, and crowned roads, in their effect upon tire wear, advocating careful loading, a low center of gravity, and running in the center of the road. There is a wide diversity of speed limitations on different makes of trucks of the same capacity, showing that for higher speeds larger tires are needed, and that standardization of speeds for different capacities is needed.

He produced a table of tire capacities, showing two standards of capacity ratings, one of which varied with the diameter of the tire, and the other of which did not. He also pointed out that usually a greater capacity was given to a dual combination than to a single tire of equal cross-section. He stated that truck makers all allowed for overloads in every part but the tires, looking to the tire maker to be the goat. He appealed to truck makers to allow an equal percentage of overload capacity for the tires.

In discussing the question of the relative merit of the dual tire as compared with a wider single-section tire, Mr. Harris stated that he had found the single tire preferable to the dual tire, up to 7 inches, the largest size which it has so far been practicable to make.

Standard Tire Sizes

J. E. Hale, of the Goodyear Tire & Rubber Co., presented a paper on "Standard Tire Sizes," illustrated with lantern slides. Mr. Hale very ably set forth the work of the S. A. E. in tire standardization, and presented a convincing argument for the restriction of tire diameters to two or possibly three sizes—32, 36 and 42 inch in fine. This review complete, he next took up the question of further standardization, standardization of load capacity for given capacity. At present there are some makes of tires of given size that are rated to carry loads that other makes of the same size are not. This often necessitates having the wheels made over in changing from one make of tire to another, and should not be.

He advocated complete standardization of sizes, capacities, and methods of attachments, although compounds, shapes of cross-section, etc., he naturally left to the individual maker. But in endeavoring to standardize carrying capacities of different sizes of tires, the S. A. E. has been confronted with the necessity of having accurate data on tire wear, and up until the present such data has not been procurable.

S. V. Norton, of the B. F. Goodrich Co., read the paper which he previously presented to the Motor Truck Club in New York City. His statements were confined to the solid tire, consisting of the causes and remedies for wear and destruction of these tires. He also made a strong plea to manufacturers for more honest load ratings, and a square deal for the tire man in regard to tire sizes. He predicted the abandonment of tire guarantees, and extolled the virtues of oversized tires.

A rather interesting fact that is not as well known as might be the case was brought up in the discussion of overloading. It was pointed out that whereas the actual weight of the vehicle and its load may be well within the safe limit, a long overhang, or a load that projects for a considerable distance at the rear will be responsible for overloading the tires by reason of the leverage which reresults.

Driver Worst Enemy To Successful Truck Operation

—

Chicago Dealer Asks for Clearing House for Drivers To Protect Owners and Dealers

"There is a foundry company in Chicago that put a careless driver on its truck with the result that in 6 months the truck was shipped back to the factory to be rebuilt. When it was returned a first-class truck driver was engaged and the result is that this truck has now been in use 4.5 years, it is still in perfect condition and the same driver is still handling it. It is not brought to our service building once a year and is a credit to its maker and its owner." In these words, H. S. Dunlavy, a Chicago truck dealer, outlined the difference between a good driver and a poor one in his paper entitled "Driver's Relation to Successful Motor Truck Operation." Mr. Dunlavy in still further showing the value economically of a good driver continued: "There is a truck user in Joliet with three Federal trucks, two of which he has had for 2.5 years and one for 6 months. He has two drivers operating them and outside of tires the maintenance on these three trucks for the entire time he has had them has not amounted to $70. His drivers are men who have worked for him for years; they drove his horse teams; some of them have been with him for 15 years.

"There should be a clearing house for truck drivers, so that motor truck owners could get some protection against carelessness and inefficiency. Motor truck dealers and branch managers should write to all of their owners asking them to give the names and addresses of their drivers. They should also be asked for such information as length of time they have been on the job; and whether they are good, fair or poor. This information should be listed on a card index field in the clearing house. Truck owners should be furnished with cards on which they could give all particulars when a driver is discharged. Such information should be entered on the index card of the respective driver.

"If this plan were put into operation, so that when an owner wished a driver he would consult the clearing house, it would not take long for the drivers to realize that unless they gave proper service, took good care of their trucks, and attended strictly to business, they would be classed as poor, if they were discharged, and would consequently have great difficulty in procuring new positions. It would have the effect of stimulating drivers to give better service. If a driver were incapable he would not get positions excepting at very poor salaries."

"Credit sales to purchasers of motor trucks must be distinguished from selling passenger cars on terms," began Walter E. Parker, President of the Commerce Motor Truck Co., in speaking on this subject. "The latter is poor business," continued Mr. Parker, "and has earned the condemnation of all economists and bankers. That the evils of this method of making sales without regard to good business principles should be visited upon motor trucks is unfair, inasmuch as the truck is a business investment capable of yielding substantial returns, and not a luxury. An economical necessity to its user, and not a convenient toy which represents only in rare instances a necessity of business."

Time Payment Plans

Mr. Parker emphasized the fact that many concerns whose credits were good and who conducted their business along conservative lines for legitimate profit were not in the habit, or prudently able to take sufficient funds from their business to pay for an entire investment of such magnitude as is represented by motor truck purchase. The cash basis of selling motor trucks was a heritage from the passenger vehicle industry, and should not be permitted to restrict the market to such a great extent as it must.

Wild-cat credit schemes were the cause of many failures, and were naturally to be discouraged. He submitted a plan, therefore, for the standardization of credit arrangements, with a method of financing and securing such ventures. The salient features of this scheme were the formation of a motor truck guaranty association to be made up of manufacturers and dealers in motor trucks, the $500,000 capital to be subscribed in equal proportions by manufacturing and selling members of the organization. Terms were based on payments down of 25 per cent. of the price, the balance to be paid within 10 months, the notes to be discounted and secured by chattel mortgages and insurance.

In further taking up the question of the time payment plan for commercial vehicles, Frank M. Gregg, president of the American Commercial Co., Cleveland, O., stated that "The deferred payment plan, when used in conjunction by the manufacturer and agent, is a powerful factor in the sale of automobile trucks. The deferred payment plan, when used by the agent alone, is weak and of little value.

He supplemented this statement by adding that any plan which leaves the making of the terms of payment to the dealer alone is not only ill-advised but is immoral in that it encourages him to take risks which he would not take.

U. S. Banks Needed in South America

Banking and Credit Are Indispensable Elements in Developing Our Trade with South America—Foreign Banks Now Reaping the Profits Aid Foreign Firms

By Donald McLeod Lay

Being a digest of a report prepared for the Department of Commerce by Edward N. Hurley.

"AMERICAN BANKS ARE IMPERATIVELY NEEDED IN SOUTH AMERICA AS A DEPENDABLE RESOURCE IN THE CAMPAIGN FOR GREATER TRADE. The growing keenness of competition with nations already thus equipped renders reliance on their support increasingly perilous." This is the essence of a report prepared by Edward N. Hurley for the Department of Commerce under the title Banking and Credit in Argentina, Brazil, Chile and Peru, being No. 90 of the Special Agent series. The report incorporates observations and conclusions, from a manufacturer's point of view, of the existing banking situation as relating to present and future American trade in these countries. The following article is a brief digest of this report.

Banking Neglected

Banking and credit are indispensable elements in developing our trade with South America. American industries are extending their sales organizations, but the banking facilitation of the trade is still left in the hands of foreign banks primarily organized for the development of the commerce of competing European nations. The functions of these foreign banks in South America are: Exchange, collections, loans and discounts, credit information and investment.

Any international banking with South America must proceed on the promise that London is the center of the world's money market. One fundamental feature of the effort of German banks to control German over-sea financing was the establishment of branches of German banks in London. Stability of exchange in London is a great advantage not only to the centralization of credits there, but the expansion of British exports to South America. Exchange on New York is quoted in the chief banking centers of South America, but bills are not offered in large number or constant supply. Although the trade between the United States and Brazil in 1912 was valued at $190,000,000, the balance of trade was adverse to the United States by $94,000,000. As between Argentina and United States the balance of trade favors the latter. At present, conditions are not propitious for the development of a larger direct export trade with the United States.

London Exchange Favored

Bankers state that exchange on New York in South America is usually at a disparity of from to 1 to 1 1-2 per cent. as compared with exchange on London. Thus New York exchange in South America sells at 1 to 1 1-2 per cent. less than London exchange and costs buyers 1 to 1 1-2 per cent. more. The large toll that the United States annually pays London can only be estimated but an idea may be gained from the fact that bills on London in 1912 were valued at £1,805,000,000, as against a total export trade of £1,231,000,000 on every one of these £1,800,000,000 sterling of which some profit was made or some commission earned.

Saving $1,316,173 a Year

Foreign banks charge from 1-8 of 1 per cent. to 1 per cent. for collections, according to the remoteness of the debtor. These banks offer the most effective avenue open to the American exporter in reaching customers. Assuming a commission of 1-2 of 1 per cent. on $526,468,815 worth of products sold by Latin-America to the United States in 1912, the total cost of payments through London would be $2,632,344. On the basis of a banker's statement that well established American banks in Latin-America would save half the commission, the saving would be $1,316,173. Credit is far more freely given in South America than in the United States. Single name paper is very generally accepted, individual houses often deal with six to ten banks and overdrafts on current account, for which the depositor pays 9 per cent., are encouraged.

Since the foreign and native banks in South America are called upon to accept drafts representing credits in the export and import trade they must maintain credit information services. Foreign banks supply their home offices in Europe with ratings and characteristics of South American firms and individuals. German trade has been extended largely by aid of longer credits than were accorded by British houses.

British investments in Latin-America are estimated at more than $5,000,000,000 yielding approximately $250,000,000 in annual interest. South American exports to the United Kingdom in 1912 reached a total of $310,210,806, so that the earnings of British investment went far to pay for these purchases. The United States has little investment in South America and American purchases from South America must therefore be paid for outright. Since our capital does not largely enter the South American field, the manufacturers of the United States lack the potent support that national investment supplies. German banks in South America are intimately related to German manufacturing industries, steamship lines and insurance and cables companies. Therefore, every influence that may be derived from the investment of German capital is intensively exerted for the extension of German commerce and prestige.

Five British Banks

Here the report mentions five large British banks in South America, the London and River Plate Bank, Ltd., London and Brazilian Bank, Ltd., Anglo-South American Bank, Ltd., British Bank of South America, Ltd., and Banco del Peru y Londras, the total of whose capital is $68,131,000. The report then takes up the development of British banks in South America along with the trade, the German banks being contrasted as organized as a stimulus and an aid for progress in markets held by others.

Three German Banks

Three large German banks are mentioned, Banco Aleman Transatlantico (Deutsche Ueberseeische Bank), Banco Germanico de la America del Sud, and Brasilianische Bank fur Deutschland. The capital of these banks totals $14,399,000. The German branch banks in South America are the result of the industrial development begun about 1870 and were organized for the purpose of providing financial accommodations for the sale of Germany's tremendous manufacturing output.

Other European banks of South America include the Banque Francaise et Italienne pour L'Amerique du Sud with a capital of $4,825,000 and the Banco Suizo-Sud Americano, with a capital of $3,860,000. The successful establishment of these two institutions shows that oversea banking is an enterprise by no means depending upon an established trade.

Argentine Trade Growing

The report then takes up banking and credit in Argentina, giving the names of the principal foreign and national banks together with statements of their capital, etc. It then takes up the monetary system, the currency being described as stable on a gold exchange standard basis protected by the government office for the conversion of currency. Argentina's foreign trade has grown more rapidly in recent years, in proportion, than that of any other nation, the United States standing third as supplying imports to the value of $57,057,508, the United Kingdom being first with $114,515,803 and Germany second with $61,703,550 for the year 1912. In regard to the export trade the United States stands fifth with $31,257,458 for the year 1912, the United Kingdom standing first with $117,125,290, Germany second with $52,105,344, Belgium third with $35,954,187 and France fourth with $34,790,189.

The curtailment of foreign investment and withdrawal of loans that brought on commercial depression in Brazil created a monetary stringency in Argentina. Land speculation inflated values and credits were widely extended. Poor crops aggravated the situation. One good result of this crisis was the return to Argentina of many wealthy families who had gone to live in Europe.

Expense Is High

The expense of banking in Argentina is much higher than in the United States, average pay of a trained clerk not doing special work ranging from $1,000 to $2,000 gold per year. Bank premises, rental and equipment are also much higher than in the United States.

Successful banking in Argentina requires a close knowledge of local conditions and the swift changes that sometimes occur in the business world. Promissory notes are extensively used, although with but one name. The negotiable paper accepted in Buenos Aires consist of promissory notes or time drafts up to 180 days. Purchases by the United States are usually covered with cash or drafts against the purchase through foreign bankers. When the Argentine producer or merchant accepts a draft for payment of exports to the United States, he discounts it at an Argentine or foreign bank.

Discount rates charged on overdraft in current account is 9 per cent. The discount rate in Argentina varies from 6 to 12 per cent.

In marked contrast with the universal use of checks in the United States, where more than 90 per cent. of business is thus transacted, checks are but sparingly used in Argentina except by large houses. Banks will not accept typewritten checks.

The clearing house now operating was established January 2, 1913, as a result of an agreement between the Banco de la Nacion Argentina and the other principal banks of Buenos Aires. The admission of a new bank to the clearing house will be determined by vote of the member banks.

Bank Would Succeed

If citizens of the United States should start a bank in Buenos Aires and manage it well, according to a prominent Argentine financier, no question exists but that it would succeed. The present time by reason of the bad condition of business is an advantageous moment to investigate the feasibility of establishing an American bank.

The report then takes up banking conditions in Brazil, giving the names of the principal foreign and Brazilian banks and explaining the monetary system stating that although Brazil adopted the gold standard the year gold was discovered in California the currency remained for many years prior to 1897 an inconvertible paper. A conversion fund was established in 1906 by means of import duties collected in gold. At present the situation is usually expressed in terms of foreign exchange. The actual currency of the country is composed of convertible and inconvertible notes and silver coin.

Progress of Brazilian commerce shows that those nations enjoying the preponderance of its trade are the two great maritime and over-sea banking powers, Great Britain and Germany. Steamship connections have also been greatly to their advantage. The collapse of the rubber trade as a result of far Eastern competition was a heavy blow to business conditions in Brazil for in the Amazon country everything had been sacrificed to rubber, although the region is ideally situated for cattle raising and the dairy industry.

Import Business Profitable

The import business, largely in the hands of foreign trading houses, is large and profitable, but the transactions are complicated by the difficulty of getting shipments through the customs rapidly. Importers are indisposed to accept drafts until they have seen the goods and are satisfied that they comply with the orders and arrived in good condition.

Any foreign bank wishing to operate in Brazil must present a petition addressed to the Government making such request and join thereto its stockholders, its memorandum and articles of association, charter of incorporation—all these documents to be duly legalized by the Brazilian Consul in the country where the bank was originally established. The expense of a foreign bank in Brazil is very high, as wages, rents, taxes, etc., are all heavy.

American Banks Needed

The feasibility for establishing an American bank in Brazil is subject to much difference in opinion. Generally speaking the business profits of prosperous foreign banks in Brazil amount to about 1-8 of 1 per cent. on collections, 1-4 to 1-2 of 1 per cent. on exchange, 8 to 9 per cent. on loans and 3-4 of 1 per cent. on cash discount. American business men constantly feel the lack of prestige which an American bank in Brazil would give them.

The report then takes up the banking situation in Chile, which taxes all capital employed in foreign branch banks 3 mills on a dollar. Banking practice resembles that in other large South American countries, the cost of living, salaries, rents, etc., being lower than either Argentine or Brazil. Consular and diplomatic officers have frequently expressed the opinion that the commerce of the United States with Chile requires more direct banking facilities. An American bank would enjoy an unusual degree of popular confidence from the start.

Peru Is Friendly

The taxes of Peru are collected under a concession at present held at the National Revenue Collecting Co., which has 4 years to run. The director of Administration of the Ministry of Finance has stated that an arrangement would be welcome whereby an American company might take over this corporation. The opportunity for establishing American banks in Peru is excellent.

Several avenues are open for the establishment of American banks in South America: Branches of American national banks, banks organized solely for American business in South America, purchase of an interest in existing native banks and banks for investment and industrial development.

The report concludes with a strong plea for American banks in South America, pointing out that a competitive era with Great Britain and Germany is here. American disadvantages are given and a brief summary of commercial methods. The report points out that the Federal reserve act, if interpreted to cover American branch banks in South America, will not facilitate credits to American business men in those countries, as it will restrict the activities of the banks too much to allow them to compete with British and German establishments.

Protecting the Investment in Car Finish

Present Garage Methods of Washing Cars Ruinous to Luster and Life of Finish—The Correct Method of Cleaning Body, Chassis, Top and Upholstery

By M. C. Hillick

CAR finish represents an investment on the part of the owner of no small value. To better acquaint himself with the character and importance of this investment let the car owner ask the local distributing agent or the automobile manufacturer concerning the processes and materials employed in painting and finishing the car. When it is understood that anywhere from fifteen to twenty-five applications of expensive material are required to complete the finish on a first-class car with the involved labor being paid for at a high rate, the finish is more appreciated.

Abuses in Washing Cars

Washing the car has been described as a simple process. But the very simplicity of the work has led up to a list of abuses which, unless corrected, promise to wreck the finish. When received from the hands of the maker the automobile is clean and neat—a thing of beauty. Why not maintain it in this condition? The car should be regularly and systematically cleaned and renovated. The varnish on the new car is always benefited by an occasional washing with clear, pure water. The car, even when not in active use, should be so cleaned at stated intervals. In summer, preferably the water should be cool. On a new car occasional washing with cold water serves to harden the varnish, and increase its brilliancy. During the winter, if the washing is performed in a warm place, the use of cold water for an occasional washing may be continued, but cold water applied in a cold place at a frigid season of the year is injurious to the varnish. When the car is being daily used, or following each period of road service, the varnish should be washed, top, if any, cleaned, and the upholstering and interior furnishings of the car renovated. What are the details of this work? First, *never wash the car in the bright sunlight. The sun dries the water up too rapidly, and causes streaks in the finish.* Always use absolutely clean water for the washing. Change the water often enough to keep it clean.

Temper Power of Hose Stream

In many of the leading garages use of the hose is strictly prohibited. In most of the great garages in Paris where the finish on the car is prized to an extent unapproached in any other city of the world, the use of the washing hose is never allowed. In establishments where the hose is tolerated it is usually provided with a rose, which serves to break up the power of the stream. In this country the indiscriminate use of the hose often, unfortunately, entrusted to the hands of roustabouts with little knowledge concerning the washing of the car, and less appreciation of its importance is responsible for the early decay and lack of durability of the finish. It is practically certain that if statistics were obtainable covering the durability of the average automobile finish they would result in an indictment against this method of car washing which would prove absolutely irrefutable. For this reason, then, we shall here advise the use of the pail and sponge to the exclusion of the hose. For the proper washing of the car body two galvanized iron pails with the necessary accompanying soft fleece wool sponges should be furnished. One pail and set of sponges should be kept exclusively for the final rinsing off of the surface. The same equipment should be provided for the chassis, mud guards, fenders, etc.

Clean Top First

Before commencing the washing operations the top, if any, should receive attention. Leather, either machine or hand-buffed, and rubber tops should be sponged off with clean tepid water, and when somewhat coated with road dust, or mud, this water should contain enough castile soap to provide sufficient alkali to cleanse the surface from such accumulations. Follow this cleaning by drying the leather or rubber with a wash leather specially kept for this purpose. If the top is of Pantasote fabric it should receive practically the same washing methods as the leather or rubber. The ordinary cleaning for a genuine mohair top consists of good brushing with a whisk broom. In case the top is too dirty to respond to this treatment it may be washed with a moderate solution of castile soap and water. Genuine mohair tops made with a rubber interlining should, under no circumstances, be cleaned with gasoline, kerosene, benzine or any other by-products of petroleum. In fact, no dissolving medium containing properties destructive to the rubber interlining should be employed in the cleaning of mohair tops.

Vacuum Cleaning for Interior

Cleaning and renovation of the upholstery of the interior of the car is accomplished by means of the vacuum cleaner operated at a pressure suited to the delicacy of the fabrics. Indeed, the modern garage is not complete without this vacuum cleaning apparatus. The work by this system can be so quickly and so thoroughly done it is hardly practical to adhere to any other method. However, in the absence of such cleaning devices a thorough brushing out with broom and brush should be given.

All removable parts had best be taken out of the car for these cleaning operations. Windshield glass, and all other glass attachments should be cleaned with one-third denatured alcohol, and two-thirds water. Dip a soft cloth, or, better still, a small fleece wool sponge, in the water-alcohol mixture, and then into some fine whiting or pumice stone flour and apply to the surface. Let this application dry on the glass, then wipe clean with soft woolen cloths, and complete the work by bringing the glass to a high polish by rubbing with tissue paper. Begin washing the car body by dipping the sponge well into the water, in order to pick up as much water as it will hold, and then begin at the top of the panels and dash the water obliquely and gently from the sponge against the panels to loosen the dirty accumulations, and cause them to drop off.

When Washing Is Delayed

Another way is to squeeze the water out of the sponge at the top of the panels, and, thereby, with the pressure of water carry away the mud or dirt. These are methods for the car that is washed immediately upon its return from road service.

Provided the car has been put away for the night unwashed, and the mud and other road refuse allowed to dry on to the finish it will harm the varnish to apply water, and attempt to remove these dry, crusty accumulations at once. All such surfaces should have plenty of fresh, clean water run down in an easy volume over the finish. Continue this practice until the dirt-encrusted surface is thoroughly soaked up. Then let the work stand for 15 or 20 minutes for the water to so act on the body of dirt and mud that under a fresh flow of water it will freely run away without injury to the finish.

In all cases the mud and dirt should be floated off by a natural flow of water rather than wiped off. This latter practice usually results in the finish being scratched and disfigured by coarse grit and dirt. It must be understood that even a water-loaded wool sponge drawn or rubbed over a dirty or mud-bespattered panel develops a scouring effect. This effect diminishes the brilliancy of the varnish, and reduces its capacity for protecting the undercoats.

The Second Washing

After concluding this first or preliminary washing of the surface a new sponge and a new pail should be taken in hand, and the surface again washed with a fresh supply of clean water. A soft wash brush, oval in form, and chisel pointed should be used to tool around surface ornaments, moldings, panel corners, and other attached body fixtures. Such places cannot be effectively reached with the sponge.

Use the same care and precautions in washing the chassis, and under no circumstances employ for the chassis the tools used in washing the car body, and *vice versa.* In this way avoid transferring grease, and oily stains from one part of the car to another.

Drying the Body and Chassis

For drying off the water from the body of the car or chassis use a wash leather, or chamois skin, so-called, entirely free from lint, and absolutely clean. Ring the skin out after rinsing off in clean water, or, if dirty, after washing out in a solution of soft water and castile soap, and beginning at the part of the car first washed, proceed to pass the skin over the surface with just sufficient pressure to take up all the water with the exception of a mist, which in the air will very quickly evaporate.

To attempt to wipe the car perfectly dry in all parts will result in injury to the luster of the finish. An erosive effect on the surface can be produced under the pressure of the wash leather, and this effect in washing the car must at all times be avoided. To clean the car in the manner as above described will require the time of one man for 2 hours. Many garage attendants and chauffeurs are free to state that the work can be done in half this time or even less, but the particular reference in this article is to first-class work well and carefully performed.

Wash Car Every 24 Hours

There are circumstances, under which a car goes into service, and is returned to the garage several times a day, making it impossible for the people in charge to apply the thorough processes above described. No car which has been in service should be left unwashed for more than 24 hours.

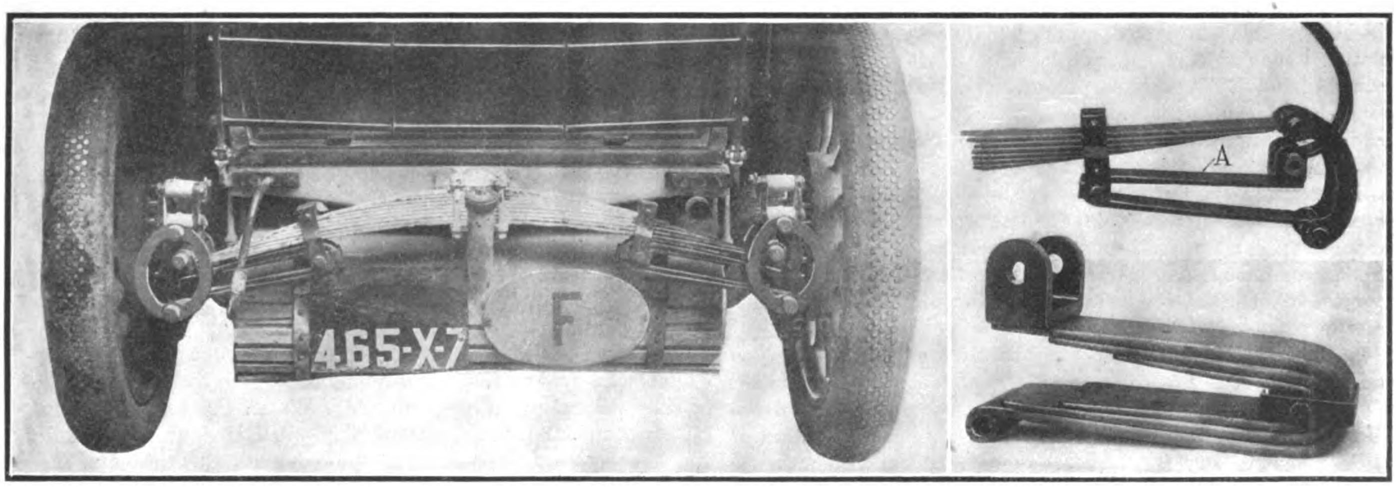
Mud Spots and Cracks Finish

Mud in its various forms in drying on a body of varnish takes up the oil from the varnish, and in so doing destroys the luster thereof. Road dirt or dust picked up on highways largely given over to horse travel is often strongly saturated with ammonia, and all such accumulations are especially destructive to the finish. Such road refuse if left to dry upon the finish, not only spots the varnish but fractures its film, and causes it to decay and crumble away.

Mud and dirt from roads traversing lime districts are likewise highly destructive to both the luster and the fabric of varnish, the latter disintegrating under the effects of the lime. Some varnishes, or in fact, a great many of them will spot under the effect of soapy or dirty water, the alkali and capillary mediums contained in these waters going at once at the luster of the varnish.

The car not systematically and regularly washed will have its finish often spotted from the effects of various gases and garage impurities. Many manufacturing and industrial cities are so poisoned with deleterious fumes that the finish on the irregularly and too infrequently washed car is spotted and deprived of its luster in a comparatively short time. Moreover, loss of luster in the finish, without any apparent spotting of the varnish, is a direct result of failing to wash the car regularly and at proper intervals.

A New Type of Supplementary Spring Construction



A NEW supplementary spring was brought out in Europe just before the war began under the title of the G.P. These devices have nearly all been of the coil spring type, generally with the springs contained in a cylindrical housing. The G.P. differs by having leaf springs of greater flexibility than the main springs, and intended to absorb all the lesser road shocks. The attachment is an elongated U spring, with one, two, or three leaves, according to the car weight. In the case of a three-quarter elliptic spring, it is carried under the main spring, one end being shackled to the extremity of the quarter spring, and the other end to the flat spring by means of a couple of curved shackle bars encircling the extremity of the quarter spring. The supplementary spring is maintained in its horizontal position under the main spring by means of a yoke on this latter. The two ends of the yoke are united by a bolt lodging in the bottom of the U springs. By this arrangement the main springs can lengthen under increased load without interfering with the supplementary fitting. The two shackle pins on the yoke, one of which rests on the top of the main spring, and the other within the U spring are fitted with vibration absorbing sleeves, so that the vibrations of the supplementary spring are not transmitted to the main spring. An advantage claimed for the G.P. suspension is that unlike coil springs it requires no attention.

The Rostrum

Claims Overheating Is Caused By Soot

EDITOR THE AUTOMOBILE:—The cause of overheating of gasoline motors is a very strange subject in that both sides of the controversy may be either right or wrong, depending upon the circumstances. Too rich a mixture and too lean a mixture have both been cited as causes and now I want to apparently contradict both sides by stating that the most heat is produced by a perfect mixture. However, neither side is actually contradicted as overheating may be caused by either too rich or too lean a mixture.

The principal reaction in the combustion of gasoline in the cylinders of a motor is the burning of carbon (C) to carbon dioxide (CO_2) and carbon monoxide (CO). One pound of carbon when perfectly burned, unites with the oxygen of 11.6 pounds of air to form CO_2 and in so doing produces 14,500 BTU, while one pound of carbon imperfectly burned to CO gives only 4,400 BTU. In the case of excess of air, the carbon still burns to CO_2 but a portion of the heat produced is used to raise the temperature of the extra air so that for a pound of carbon less than 14,500 BTU is available for work. This process continues up to a point where the heat consumed by the excess air is so great that combustion cannot be maintained.

As a perfect mixture so evidently produces the most heat, the question naturally arises as to why a motor does not overheat with a perfect mixture but does overheat with any other mixture.

In the case of a perfect mixture every pound of carbon gives 14,500 BTU available for work and the temperature falls rapidly as the BTU are given up in work and to the cylinder walls.

When there is an excess of carbon, too rich a mixture, a portion burns to CO so that instead of having from each pound 14,500 BTU a lesser amount is available. However, in order to produce the same amount of work the same number of BTU must be available which means that more than one pound of carbon must be burned. A portion of the heat is used to raise the temperature of the CO, so that in order to have 14,500 BTU available for work, a greater amount, proportional to the CO, must be produced in the cylinders. This excess heat is not only unavailable for work but the mixture is sooty so that the passage of heat through the cylinder walls is retarded: hence overheating.

The conditions are similar in the case of excess air, too lean a mixture, except that in this case the extra heat must be produced to raise the temperature of the excess air. Here the carbon is burned to CO_2 with the maximum production of BTU so that a very large excess of air can be heated: hence a greater liability to overheat with a lean than with a rich mixture. With the lean mixture the case is aggravated by the fact that burning will often continue entirely through the exhaust stroke. In fact the flash back in the carbureter is caused by the mixture burning when the intake valve opens.

However, in actual practice overheating occurs more frequently from too rich than from too lean a mixture for the reason that the lean mixture gives notice of its presence by popping in the carbureter.

New York City. C. J. MORRISON.

—We do not agree with your explanation of overheating. This trouble is entirely due to the greater amount of wall surface that is exposed to the heat due to the slower combustion of the charge.

With an improper mixture less power is developed and therefore under a given set of conditions a greater throttle opening is required, but the actual production of heat for a given power requirement should be about the same whether the mixture is too rich, too lean or just right. In other words when the motor is called upon to develop a certain horsepower it may require the formation of 100 BTUs per explosion stroke to give this power. If the mixture is correct then these 100 BTUs are produced without waste of fuel and with a minimum throttle opening, but if the mixture is too rich, for instance, while a larger throttle opening will be required and more fuel will be drawn into the cylinder, only about 100 BTUs are necessary to produce the power.

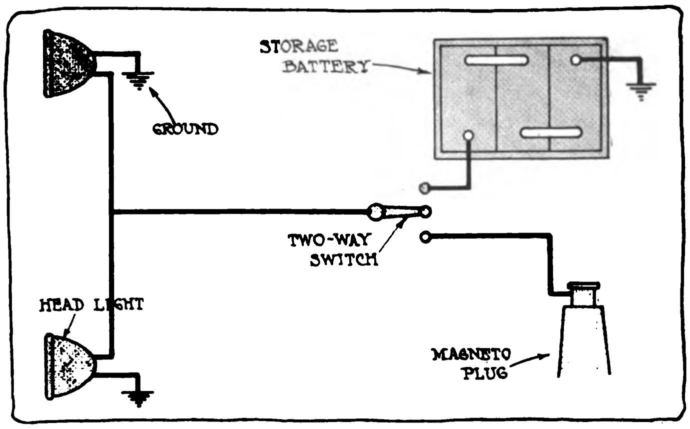


Fig. 1—Diagram showing wiring of storage battery and Ford magneto for electric lights

Recommends Extra Treads

Editor THE AUTOMOBILE:—I have tried the use of a worn out shoe over another as a tread, but without success as it is impossible to keep it on. I have been using, however, treads, made for this purpose, which are made of rubber with piano wire in the sides so that when the tire is inflated it can not budge. The cost for 3 1-2-inch tires is but $6. They are the finest things of the sort which I have ever used. I have one at present on a tire which is 3 years old, and has gone over 7,000 miles on three cars, has been discarded several times because of being worn down through the first layer of fabric. During this time it has been lying on the floor of the garage without attention. About a month ago I put on one of the treads and have run it 800 miles and it is still as good as ever.

Washington, D. C. DR. J. RUSSELL VERBRYCKE, JR.

Reader Wants Information on Extra Casings

Editor THE AUTOMOBILE:—I note in your issue of September 24 an answer to my query of September 10 relative to using old casings over new. Mr. W. M. Prichard, Coolidge, Tex., very kindly informs us that such is done successfully in his section and gives instruction for adjustments, etc. Does Mr. Prichard mean to say he uses casings of the same circumference; or larger size over smaller ones? I am using a Ford and have four casings with good treads but the side walls are not safe.

Following his directions, I find that it is impossible to fit a 30 by 3 casing, when tread is practically new on both, over another 30 by 3. Perhaps he means to use casings that have been used on pavements with badly worn treads. Will he kindly give us a little more light on the subject?

In your issue of October 1, Mr. L. C. Kyle, Gladsden, Ala., gives his experiences as a failure in using old casings over new. Did Mr. Kyle remove the bead on casings before fitting and were his under casings badly worn? Will he kindly inform us and if others have had experiences that are of worth, will they not let your readers know of them?

Back Bay, Va. W. B. DULING.

To Wire Ford Electric Lights

Editor THE AUTOMOBILE:—Will you kindly tell me what is wrong with the method of wiring for electric headlights on a Ford as shown by the attached sketch? I wired it in that way to be sure of having at least one light in case either bulb should burn out. I thought I saw such a method in THE AUTOMOBILE some time ago, but cannot find the copy.

The lights burn all right so long as the engine receives its current from the batteries, but as soon as I throw the switch to the magneto the engine stops. Where is the trouble?

Gladstone, N. J. J. M. HARPER.

—You have not shown where the battery is connected and therefore it is impossible to say where you have made a mistake in your connections.

A simple diagram that you might use is shown in Fig. 1. A two-point switch directs the current from the storage battery or the magneto as desired.

Specifications of Medium-Priced Cars

Editor THE AUTOMOBILE:—We would like to have the factory price, bore and stroke, piston displacement, wheelbase, horsepower size of tires and style, whether demountable or quick detachable, of the 1915 models of each of the following cars: Overland, Buick, Studebaker, Regal, and Maxwell.

Springfield, Mo. DIEFENDERFFER IMPLEMENT CO.

—Below is a table giving the information you desire:

Make	Model	Cyls.	Bore and Stroke	Piston Disp.	Wheelbase	S.A.E. h.p.	Tire Size	Type of Rim	Price of Car
Overland	80	4	4.12x4.5	240.5	114	27.2	34x4	Dem.	$1075
Overland	81	4	4 x4.5	227.5	106	25.6	33x4	Dem.	850
Buick	C-55	6	3.75x5	331.25	130	33.75	36x4.5	Dem.	1650
Buick	C-36	4	3⅝ x5	220.9	112	22.5	34x4	Dem.	1185
Buick	C-37	4	3.75x5	220.9	112	22.5	34x4	Dem.	1235
Buick	C-25	4	3¼ x3¼	165.68	106	22.5	32x3.5	Dem.	1050
Buick	C-24	4	3¼ x3¼	165.68	106	22.5	32x3.5	Dem.	900
Studebaker	C-4	4	3. 5x5	192.4	108	19.6	33x4	Dem.	985

Increase of Tire Pressure with Temperature

Editor THE AUTOMOBILE:—In the October 1 issue of THE AUTOMOBILE I noticed a formula for determining the increase of tire pressure with temperature. As I am not much of a mathematician I would like to know whether you could not express this in the form of a curve, in order to save the trouble of calculating the pressure increase?

Lyons Falls, Vt. E. W. W.

—A series of curves for determining the increase of tire pressure with temperature is shown in Fig. 2. For instance, if the original temperature is 60 degrees and the tire pressure 70 pounds, then the point representing these two pressures is located on the diagram. Supposing that the temperature increases to 95, the new pressure is found by following the diagonal running through the point just determined until the intersection of this diagonal with the 90-degree temperature line is reached. The pressure line running through this point indicates the new pressure.

The pressures are gauge pressures.

Where to Buy Strong Springs

Editor THE AUTOMOBILE:—Some time ago we saw a spring starter advertised in THE AUTOMOBILE, and would like to know if you can give us a list of the addresses of the manufacturers of these devices. We are not in the market for a starter, but wish to procure some strong springs of this character.

Portland, Me. E. T. B.

—Spring starters are manufactured by the following concerns, according to the *Automobile Trade Directory:*

American Ever Ready Co., 316 Hudson street, New York City.
Automatic Devices Co., Galesburg, Ill.
Elder Mfg. Co., 2305 N. Illinois street, Indianapolis, Ind.
Gardner Engine Starter Co., 1451 Michigan avenue, Chicago, Ill.
Modern Auto Starter Co., S. Michigan avenue, Chicago, Ill.
J. W. Tudor, 35 Congress street, Boston, Mass.
Universal Mfg. Co., Racine, Wis.

As the above concerns probably buy their springs from specialists in this line of work it might be better to write directly to some of the manufacturers of machinery springs. Below is a partial list from the *Automobile Trade Directory:*

American Steel & Wire Co., 72 West Adams street, Chicago, Ill.
Wallace Barnes Co., Bristol, Conn.
Fort Pitt Spring & Mfg. Co., McKees Rocks, Pa.
Wm. D. Gibson Co., Huron and Kingsbury streets, Chicago, Ill.
Harrow Springs Co., 745 East Vine street, Kalamazoo, Mich.
M. D. Hubbard Spring Co., Pontiac, Mich.
N. Y. Wire & Spring Co., 586 Washington street, New York, N. Y.
Sabin Machine Co., Montpelier, Vt.
Tuck Mfg. Co., 74 Ames street, Brockton, Mass.

Concrete for Garage Construction

Editor THE AUTOMOBILE:—I write to know if you will advance a little advice to help in the planning of a small garage for accommodating a runabout and touring car. Have a small piece of property—50-foot front—and there is room

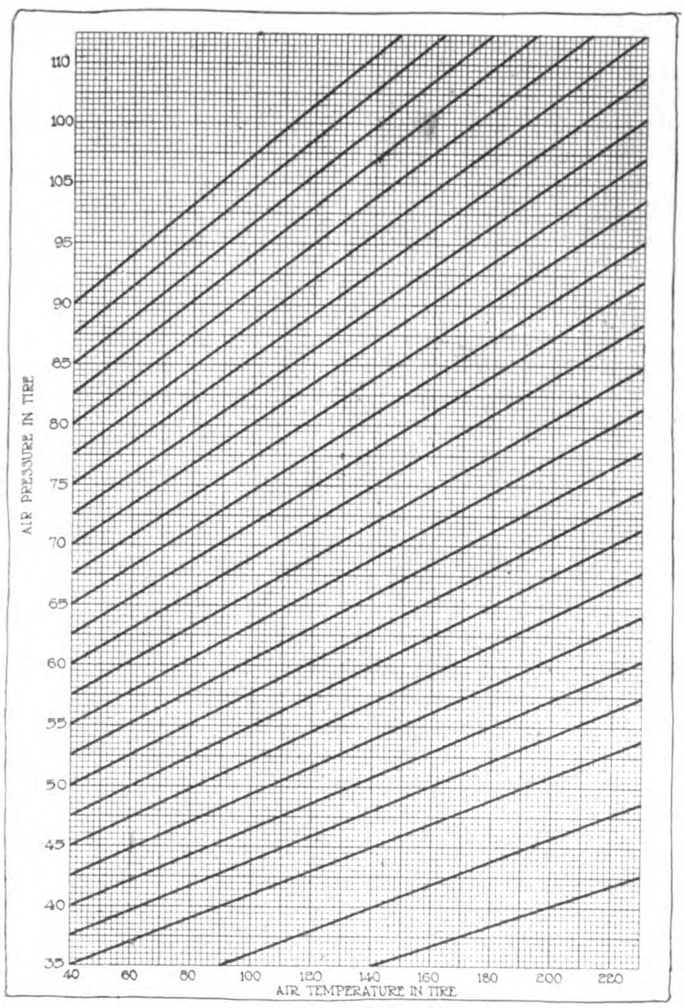

Fig. 2—Curves showing increase of tire pressure with temperature

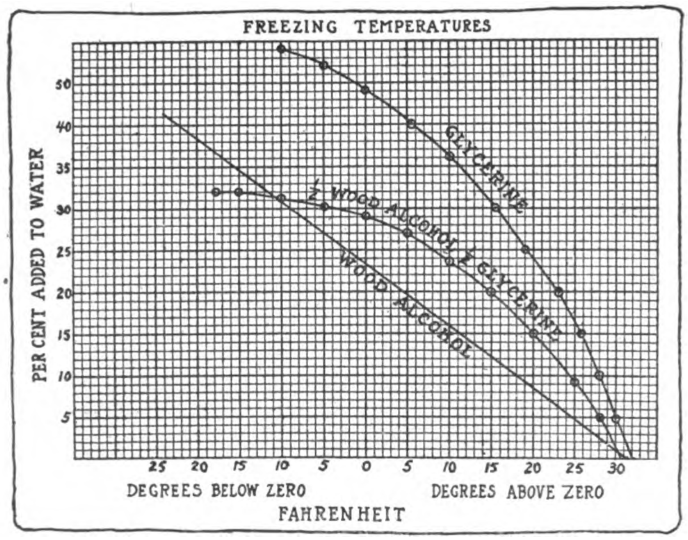

Fig. 3—Curve showing glycerine, wood alcohol and half and half added to water for different freezing temperatures

enough on the side to put down a drive to the street. The lot is 100 feet deep. I had a concrete proposition in mind. Pipes run (under ground) from a hot water heater in the house to the garage to keep it in fit condition for the winter. Thought of a second floor for a billiard table for my boys. I thought of concrete to get away from a frame or galvanized iron frame work, doing away with the paint.

Waterbury, Conn. T. M. BAKER.

—Make your garage about 15 by 20 feet with double doors at the front and windows at the sides and rear to give plenty of light. A garage this size will afford plenty of room for two cars and also will allow the placing of a work bench across the rear. Slope the floor so that water will drain off it. It will also be well to have a pit so that repairs to the under part of the car can be made without inconvenience. Piping hot water from the house is an excellent idea, care should be taken, however, to lay the pipes deep in the ground and if possible they should be insulated. The deeper the pipes are put the less they will be affected by the frost.

Concrete is an excellent material for garage construction and is probably the most durable, but you can obtain satisfaction from any of the common materials.

A billiard room on the second floor is an excellent idea; care should be taken to make a solid floor so that the weight of the table will not cause the floor to settle and throw the surface of the table away from the horizontal.

Formula for Flywheel Weight

Editor THE AUTOMOBILE:—Will you please publish the formula for determining the flywheel weight for a six-cylinder gasoline motor. The motor in question has a 3 3-8-inch bore, by 5-inch stroke with about 50 pounds compression cold.

New York City. M. C. F.

—The necessary flywheel weight can not be calculated without knowing more than the three facts you have given. The weight of the reciprocating parts, the speeds at which the motor normally operates, and several other factors must be taken into consideration.

The flywheel is for the purpose of storing energy. First because the power impulses are intermittent and second because the power demanded from the motor may momentarily become excessive and under these conditions the flywheel may be called upon to aid in propelling the car—as, for instance, when the clutch is engaged suddenly. If the flywheel were very small, the motor would be stalled even with the throttle wide open, but if the flywheel is large the energy in it will be used in starting the car.

When an explosion occurs, all the energy that is not needed for propelling the car throughout this stroke is used in slightly accelerating the flywheel. Supposing that under certain conditions the flywheel on a one-cylinder motor increases its speed from 500 to 550 revolutions per minute during this stroke. Then during the following exhaust, suction and compression strokes it will gradually slow down to the original speed of 500, the drop in speed representing the amount of energy given up.

The inertia forces produced by the movement of the pistons and connecting-rods also have their effect. During each stroke the piston and connecting-rod are at rest at the beginning of the stroke, they are then brought up to full speed near the center of the stroke, which may be 2,000 or more feet per minute, and then they are slowed down again. This is all done by means of the flywheel. The energy that is stored in it by the slowing down of these parts being given up to it by their acceleration during the beginning of the following stroke. Whenever the flywheel gives up energy it slows down and when it is given energy it speeds up slightly. These forces cause an alternate speeding up and slowing down of the flywheel during each stroke, the amount depending on the size of the flywheel with respect to the inertia of the reciprocating parts.

Thus it is seen that the design of a flywheel requires that account be taken of all these matters. It is necessary to assume the pressure diagram during the complete cycle and then, knowing the inertia of the moving parts, the effective turning effort on the crankshaft can be calculated. Knowing this, a suitable size of flywheel can be selected.

Remedy for Overheating

Editor THE AUTOMOBILE:—Those Ford owners that are troubled with overheating, may often overcome this difficulty by drilling 1-4-inch holes in the upper corners of the plates covering the valve mechanism.

I have also found that a slipping cone clutch with a leather face may be made to work until home is reached by throwing some granulated sugar on its face.

Asheville, N. C. C. B. WILSON.

Anti-Freezing Mixtures to Use

Editor THE AUTOMOBILE:—I am desirous of obtaining information in reference to freezing mixtures, for motor cars. Will you kindly advise me regarding any literature which you have published on this subject?

Toronto, Ont. J. C. ROYER.

—We have no published literature on the subject but the main features of the different freezing mixtures may be briefly told.

There are three anti-freezing solutions that have been used extensively and which have proved satisfactory. They are alcohol, glycerine and calcium chloride. There are many others that have a low enough freezing point but are objectionable because they evaporate quickly, do not carry the heat away fast enough, corrode the parts of the cooling system, leave a deposit in the radiator, do not flow freely or are too expensive.

A solution of alcohol in water most nearly fills the requirements of a perfect anti-freezing mixture. Either wood or denatured alcohol may be used and can be purchased at any drug store for about 60 cents a gallon. The advantages of alcohol are that it is very easily handled and has no corrosive action on the metal parts of the cooling system. Wood alcohol has a lower freezing point than the denatured product so a weaker solution is needed for any given condition, but this advantage is more than offset, in most cases, because with the former more is lost by evaporation, due to its lower boiling point. This necessitates adding wood alcohol more often than is the case when denatured is used, in order to keep the solution up to normal strength.

The percentage of alcohol, by volume, to give a certain freezing point can be obtained from the curve Fig. 3, or from the table below:

Freezing Point, Degrees Fahrenheit	DENATURED		WOOD	
	Alcohol, Per Cent.	Water, Per Cent.	Alcohol, Per Cent.	Water, Per Cent.
10	28	72	17	83
0	40	60	24	76
10	52	48	31	69
20	63	37	38	62

So little water is lost by evaporation that it is only necessary to add alcohol to the system, from time to time, to replace that which is used up.

Glycerine and water have also been used extensively for the reason that the boiling point of glycerine is about the same as that of water, so very little is lost by evaporation. The use of glycerine is found objectionable, however, because when enough is added to produce a low freezing point it rots the rubber hose connections and is so gelatinous that it does not circulate readily, especially is this true when it is used in a thermo-syphon system. The proportions of glycerine and water to use are indicated by the curve Fig. 3 or may be obtained from the table:

Freezing Point	Glycerine	Water
+28 degrees Fahrenheit	10 per cent.	90 per cent.
+15 degrees Fahrenheit	30 per cent.	70 per cent.
+ 5 degrees Fahrenheit	40 per cent.	60 per cent.
0 degrees Fahrenheit	48 per cent.	52 per cent.
— 5 degrees Fahrenheit	54 per cent.	46 per cent.
—10 degrees Fahrenheit	58 per cent.	42 per cent.

The difficulties in the way of using glycerine and water alone have led to the use of a mixture containing alcohol in addition. In this way a solution is obtained that has, in a large measure, the good points of both alcohol and glycerine. The presence of the glycerine raises the boiling point, thereby reducing evaporation, yet the glycerine is sufficiently diluted to allow a free flow and to reduce its action on the hose connections to a negligible amount. The alcohol and glycerine are generally added in equal parts to the water, the amount depending upon the freezing point desired. Fig. 3 shows the percentage of mixture to add or this may be obtained from the accompanying table:

Freezing Point	Mixture	Water
+20 degrees Fahrenheit	15 per cent.	85 per cent.
+15 degrees Fahrenheit	20 per cent.	80 per cent.
+10 degrees Fahrenheit	24 per cent.	76 per cent.
+ 5 degrees Fahrenheit	27 per cent.	73 per cent.
0 degrees Fahrenheit	29 per cent.	71 per cent.
— 5 degrees Fahrenheit	30 per cent.	70 per cent.
—15 degrees Fahrenheit	32 per cent.	68 per cent.

Calcium chloride in water is another solution that has been used with success. When purchasing calcium chloride it is very important to ask for the chemically pure salt as the commercial variety contains free acid which reacts on the metal parts of the cooling system. If it is impossible to obtain the former, the latter may be made fit for use by neutralizing the acid. To do this, add ammonia or soda ash gradually to the calcium chloride solution until blue litmus paper no longer turns pink when moistened with the solution. The amount of calcium chloride to use may be found from the curve, Fig. 4, or from the table:

Pounds of Calcium Chloride per Gallon	Freezing Point, Degrees Fahrenheit
2	18.0 above zero
3	1.5 above zero
4	17.0 below zero
5	39.0 below zero

Many other anti-freezing liquids have been experimented with but have been found to be inferior to those described. Various oils, including lubricating oil and kerosene, have been tried but these cause decay of the rubber hose connections, lack sufficient heat capacity, and in many cases evaporate too rapidly. There are any number of salts beside calcium chloride that will give a low enough freezing point but are not suited for use because of their high cost or action on the metallic parts of the cooling system. It is for the latter reason that common table salt and sal-ammoniac are not employed.

Herewith is a list of makers of anti-freezing solutions:

Blue Ribbon Mfg. Co., 27 Baldwin St., Boston, Mass.
Cincinnati Oil Works Co., Cincinnati, O.
Esy Mfg. Co., 1466 Michigan Avenue, Chicago, Ill.
Globe Soap Co., Cincinnati, O.
Hall-Thompson Co., Hartford, Conn.
Horsey Mfg. Co., 6104 Euclid Avenue, Cleveland, O.
Lubro Oil Co., 116 Prospect Ave., N. W., Cleveland, O.
Northwestern Chemical Co., Marietta, O.
Rub-On Mfg. Co., 89 Brayton St., Buffalo, N. Y.
Wadsworth-Howland Co., 225 Carpenter St., Chicago, Ill.

Aluminum a Good Piston Material

Editor THE AUTOMOBILE:—I would like your opinion of a piston head made of an alloy such as Parsons manganese bronze or a special bronze such as used for bearings, or even aluminum.

I would like to know why one of the above metals is not used in making piston heads instead of cast iron. I understand that cast iron is a good deal cheaper, but it seems that a piston made of one or the other of the above mentioned alloys would be much better on account of the fact that they would not be so apt to score even though they were made to fit fairly tight.

In making a piston head of cast iron I understand that they make an allowance for expansion of from .010 to .015 at the top and as much as .005 to .008 at the bottom. This makes a rather large space between that and the cylinder wall which tends to make the compression poor until the parts have heated.

Now would it not be better for a piston to be made of such metal as I mentioned above and not allow near so much clearance, as we know that the two metals will run together without scoring. There may be something that I cannot conceive of which would make the idea impractical and therefore I would like to have your opinion.

Marlboro, Mass. H. E. MOINEAU.

—Aluminum has been used as a piston material, and with success too. Parsons manganese bronze has a different coéfficient of expansion from that of iron, and is probably not used for this reason. If by special bronze used for bearings you mean ordinary white brass, this is objectionable because it is too soft, very heavy and possesses a comparatively low melting point, due to the fact that it is composed of about 30 per cent. zinc and 65 per cent. tin.

The clearance you have named is large for motors with ordinary bores. Half or one-third these amounts would more nearly approximate standard practice. This clearance is measured when the motor is cold. When it becomes warm, the expansion of the piston decreases the actual working clearance. Of course, the cylinder expands also, but not as much for the reason that it does not become so warm.

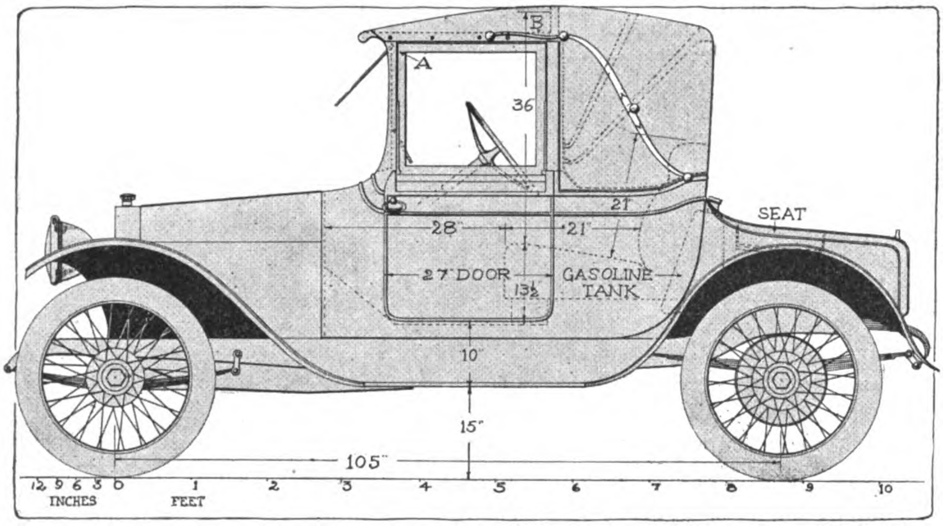

Fig. 1—Side elevation of convertible runabout body, giving principal dimensions

A Convertible Body Design for Runabouts

Closed Form for Winter Use May Be Readily Transformed to Open Car—Conservative Style

By George J. Mercer

THE problem of the hour is to get a suitable winter body for the runabout. It is more difficult to find either a suitable stock body or a design that will be right for a small than for a large car. The latter are generally listed by the manufacturers with both open and closed bodies and in addition body builders carry in stock new and used bodies that can be easily fitted to the large chassis.

The runabout is a car that the owner drives himself, and although the open body can be almost anything that is light and will accommodate two, the closed body is more pretentious and must conform to the owner's individual requirements, and, since the advent of the flush side and blended hood and cowl, it is more than ever necessary for the body to be designed individually for the car in order to have a harmonious effect.

The light-weight, two-passenger car is popular on account of its economy in upkeep and lower tire expense, but to make it an all-year car provision must be made for winter use, and in order to have the closed form as comprehensive as possible, a convertible body, Figs. 1 and 3, is most suitable for the owner who is willing to spend the money.

Not a Cheap Design

This body design is not cheap to buy; the price will vary several hundred dollars according to the shopping abilities and inclination of the purchaser, but the average price will seem large because the body price will equal, if not exceed, the first cost of the average light car.

This design must be well made, be nicely upholstered and painted and proportioned to the chassis on which it is mounted. The illustration shown is of a 105-inch wheelbase chassis having wire wheels and 32 by 3 1-2 tires. The drive is left with center control, and the mudguards and the angle of the steering column are left undisturbed. The car is low. The dimensions, Fig. 1, show 15 inches from the ground to the running board and 10 inches to the door. The interior dimensions in width and length are generous so as to allow for the maximum thickness of upholstery on the sides and back. The seat is low to suit the runabout steering wheel, so the total height is low, because the headroom is registered from the top of the cushion. This cushion is extra wide, Fig. 4, and the control can be operated freely between the driver and the passenger, the doors are wide, not only allowing plenty of entrance room, but also creating ample window space for safe driving, and the closed leather quarters at the rear of the doors, add an air of comfort to the interior when the weather is inclement, and when the days are fine the top can be lowered, Fig. 3, and the advantages of an open body obtained.

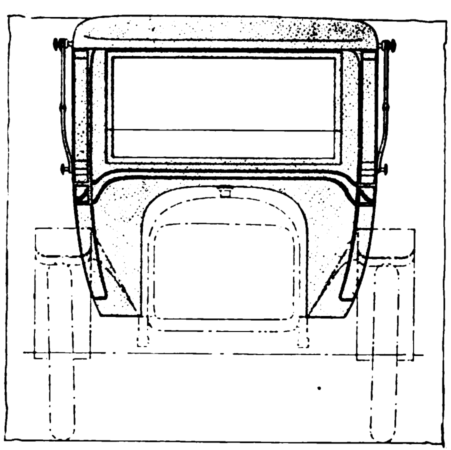

Fig. 2—Front view of convertible runabout body

Top Not in Way

Fig. 3 shows that the top will fold low and not too far back to allow of the use of the disappearing seat at the rear. This seat is wide enough for two small persons and there is luggage space in the rear compartment. A 17-gallon gasoline tank is at the forward end.

On this view it will be noticed that the front posts do not fold down. They are left stationary and form a rigid support for the windshield, which is divided, the upper part swinging outward to form the visor when it rains and the lower swinging inward to permit the cool air to enter.

The construction of the body is wood framing and aluminum panels and moulding, the upper pillars are of wood and the moving parts are made light to make the operation of raising and lowering easy.

The cowl, Figs. 1 and 4, is blended with the hood and on the side elevation the line is continued up the front pillar and terminates with a scroll on the toprail. This scroll is one of the features of the design and finishes the necessary overhang of the top beyond the front light.

The principal over-all dimensions are indicated in the several views. The extreme length from the dash to the rear 92 1-2 inches and from the dash to the back of the top 61 1-2 inches. The height, Fig. 4, is 52 1-2 inches from the top of the chassis to the top of body. The width overall is 52 inches.

Leather Best Material

The style of body here shown is generally called a coupe-landaulet. This convertible body type is becoming more popular, because it has the double advantage of the open and the closed body. The method of raising and lowering of the top has improved within the last few years and when the top covering is of flexible goods the task is quite simple. Leather makes the best looking top and for fine work it is the only thing used, despite the fact that it makes the folding of the top more harsh than the lighter weight waterproof material.

How It Folds

The operation of folding this top is to release the front pillar fastener A, Fig. 3, and release the button fasteners on the sides of the toprail. The toprail is then raised at the front until the dowel pin in the back end of the toprail at B, Fig. 1, slips out of the plate hole in the pillar, the toprail then drops parallel to the pillar and is guided and controlled by the guide.

The side joints are then released and the top folds as in Fig. 3. Sometimes the guide is concealed and placed inside the top, but this necessitates the front end of the body being nearly as wide as the middle. In the design illustrated in Fig. 2 the front is gradually narrowed until it blends with the cowl and this can only be accomplished by having the guides outside as illustrated. This form of top has the regulation flappers on the doors for holding the glass frames and in folding the top the glass is lowered as in the ordinary landau.

For Two Wheelbases

This body design is right for a chassis having either a larger or shorter wheelbase. If shorter the rear compartment will have to be shortened and the rear guards will have to be fitted to the body sweep. With a longer wheelbase, the alteration will be simply to make the rear compartment cover the chassis frame. In any case the steering column should have the angle suitable for a runabout, say not more than 37 degrees.

This will make the body low by placing the seat low. The engine hood should suit the body design. This is not an expensive alteration, and the benefit to the design is out of proportion to the outlay. Five dollars should be enough to cover this cost if only a new top is added to the hood, as the lower sides can in most cases be used again on the redesigned hood.

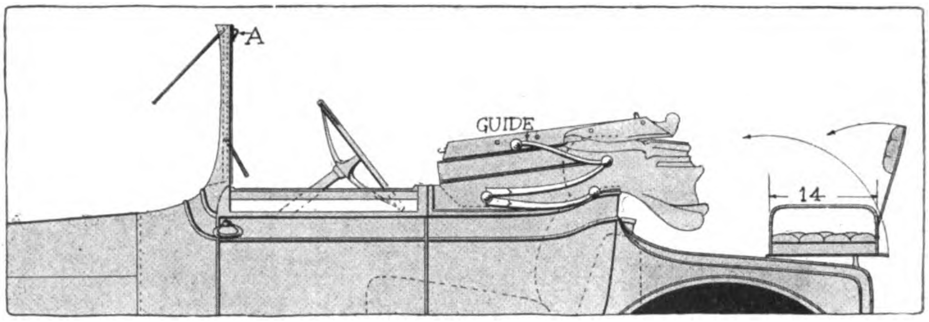

Fig. 3—Convertible runabout body with top folded down and rear seat open

The gasoline tank will have to be special on account of its shape, and it is better to have the filler plug show through, as is easy to test the quantity of gasoline in the tank.

Weighs 800 Pounds

The weight of this body will approximate 800 pounds and it is feasible to have a child's seat that will fold under the cowl and be located on the right side. This is not shown because the rear seat will take care of any additional passenger except small children.

Ordinarily the trimming for the interior of a closed body is cloth throughout, but for this design a departure is suggested that has had satisfactory results. The inside of the top and the sides and back down to the seat sides and back are trimmed with a lightweight brown and gray mixed cord cloth with lace to match. The seat cushion, the seat sides and back and the doors are trimmed with black imitation morocco leather. The carpet matches the cloth and the metal appointments are silver or nickel. The woodwork is either walnut or mahogany.

The toilet appointments are very simple, being only small cases on the doors and door pockets. The instrument board will contain the clock and speedometer. The inside lighting is produced by a small reading lamp on the front of the rear bow.

The roof covering should be landau top leather of the finest quality to insure good wearing. This top leather is fastened by the ordinary bead moulding on the hinge pillar and along the lower edge, but from the hinge pillar forward it is fastened only by glove fasteners to the toprail except across the front rail, where it is securely nailed. Along the sides the glove fasteners simply hold the leather from being blown up by the wind. These fasteners are released when the top is folded because the toprail must turn end for end when in the position shown, Fig. 3. The same thing applies to the head lining, which is free from the toprail except at the front end. The loose part is reinforced to hold its shape as no fasteners are used inside.

Anyone Can Build It

Figs. 1, 2, 3, 4 and 5 show the open and closed side view of the body. In Fig. 3 the seating and the outline of the body are shown and Figs. 4 and 5 show the back and front elevations. The principal dimensions are indicated and the scale rule on the several views enables the reader to get the size and dimensions of all the parts. These different views are accurate and there is enough information to enable anyone to reproduce the job.

The color of the painting is preferably a green or blue. The top leather must be black and the paint must harmonize with this, although there are some light colors such as yellow that will look well with the black top leather. This is a matter of choice and the design will give the same degree of comfort and satisfaction regardless of the paint.

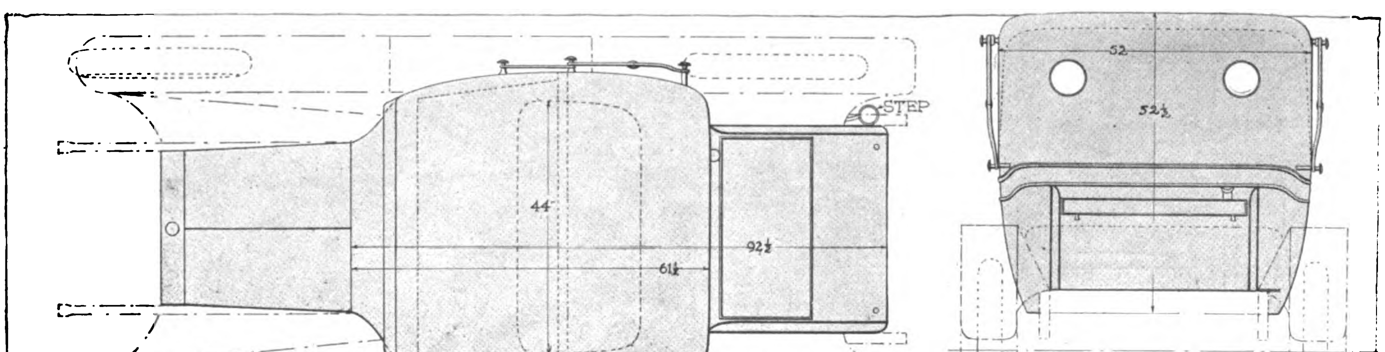

Fig. 4—Left—Plan view of convertible runabout, showing over-all dimensions. Right—View of body from the rear

The Engineering Digest

Facts and Theory of Metal Spraying by the Schoop Method, with Some Data of the Cost

ACCOUNTS of the Schoop method for spraying a permanent or removable metallic surface—or in fact a surface of any fusible material—upon objects of the most varied nature and form have been given several times in these columns (for example in THE AUTOMOBILE of Feb. 12, 1914, pages 408-409) and have been especially explicit with regard to the mechanical construction of the apparatus; yet new facts relating to the method and its results are coming to notice through the gradual development of the process and the experience gained by those who have taken it up. From the state of a promising invention it is now entering among the work methods which are analyzed and whose results are classified and tabulated for different sets of conditions. A report on it rendered to the Institute of Metals in London by R. K. Morcom is recapitulated in the following:

History of Metal Spraying

Practical experience is demonstrating how apparatus of increasing technical convenience for spraying uniform metal deposits on other objects may be made. The earliest attempts were carried out by melting the metal in a pot, forcing it through a fine nozzle under high pressure, and then with steam or a gas spraying it onto a surface. Such apparatus was in many ways troublesome, and the use of it was practically confined to metals and alloys of low melting point. The spraying medium was kept hot by various devices, and an attempt was made to keep the metal molten right up to the moment of application.

The fact, however, was observed that under conditions of temperature and expansion of the gases precluding that the metal could have been molten throughout the process adherent coatings were sometimes formed. These experiments and careful observations of the spreading and adhesion of bullets fired at an iron plate suggested the next stage of development.

Metallic powders were driven at high velocity against the body to be coated by means of gaseous jets expanded from considerable pressure, and the results achieved were a great improvement.

To produce the metallic powders the metal had of course to be subjected to one of the known pulverizing methods, such as distillation, grinding or spraying. The suggestion that the pulverization and the deposition could be combined in one apparatus was then made by Schoop, and his researches resulted in the perfecting of the apparatus covered by his colleague Morf in British Patent No. 2801 of 1912 and illustrated in Figs. 1 and 2 herewith.

The Present Process

The essential parts of the machine, or "pistol," as it is called, are a combined melting and spraying jet and a feed mechanism. The metal in the form of rod or wire is fed to the melting flame. The flame can be formed by coal gas, water gas, acetylene, hydrogen, etc., burning in air or oxygen according to the metal used. The gases are supplied at such pressures as to prevent blowing out and to secure a highly deoxidizing flame. The spraying jet can be of carbon dioxide, nitrogen, air, steam, etc.; it is fed at such a pressure as to produce a sufficiently high velocity for successful coating. The various pressures must carefully be kept constant by accurate gauges and reducing valves.

The feeding of the wire is accomplished by a small pneumatic motor driven by the spraying medium either in series or parallel with the main jet.

The dimensions of the wire, nozzle and feed mechanism vary with the different metals, and the nozzles and feed mechanism are so designed as to be readily interchangeable.

For small work hand operation is sufficient; but probably,

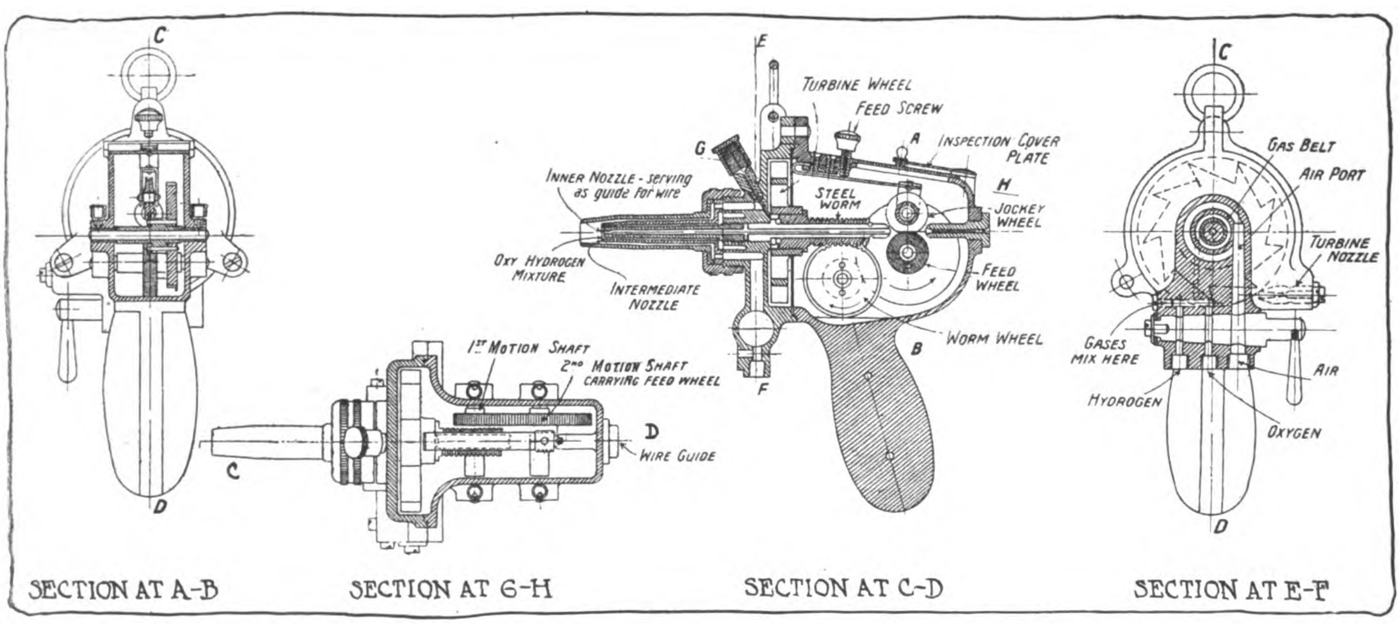

Fig. 1—Mechanism of the Schoop-Morf metal spraying pistol in four sectional views

when large work is undertaken, it will prove convenient to have mechanical traverse and control.

To obtain the best adhesion, the surface onto which the metal is sprayed must be thoroughly clean and of an open nature to give a key for the deposit. Sand blasting with sharp sand has been found best. Such surfaces as fabrics, wood, unglazed earthenware and asbestos require only freedom from grease, as their surfaces give a natural key. Despite the intense flame used, celluloid and even explosives can be safely metal-sprayed, and a brief account of the theory so far developed to explain the operation will make this fact seem less surprising.

Theory of Deposit and Cooling

The melting jet, Fig. 2, is focused at A on the tip of the wire. The spraying jet, cold from expansion, strongly draws forward the products of combustion in the center of its cone and by its draft drags off minute particles of metal, either in the plastic or the molten state. The central cone therefore consists of metal particles, some cooled to solidity, some molten and some perhaps gaseous, all surrounded by a protective reducing atmosphere. This cone is hurled forward with great velocity onto the object to be coated, BC, by the outer jet.

With a given design of jet there is only a certain volume left by the air jet which can be filled with flame, and this flame has a limiting temperature which cannot be exceeded. The wire passing through this cone of flame receives heat, partly by radiation but chiefly by conduction, and becomes melted; but there is a definite limit to the amount of heat which can be picked up by the wire passing through the flame and a definite limit to the rate at which it can be melted. This cannot be increased by forcing more gas into the flame, as the extra gas is merely blown away by the air jet. It is possible to increase the rate of melting by shaping the nozzles so as to leave room for a larger cone of flame, and experiments are in progress on this point.

There is therefore a definite most economical quantity of gas which should be used in the pistol, this quantity being about 1.5 cubic foot of hydrogen per minute and 0.5 cubic foot of oxygen, or about 0.8 cubic foot of coal gas to 0.65 cubic foot of oxygen, for the present standard designs.

For refractory metals these quantities may be increased slightly, as a slightly higher temperature can be obtained if the burning gases are under a pressure greater than atmospheric, and this occurs when the gas quantities are increased, the inner surface of the air jet acting to some extent as an inclosing wall to the flame. On the other hand, for the more easily fusible and oxidizable metals, such as tin, lead and zinc, it is advisable to keep the gas quantities rather below the figures given, so as to avoid any possibility of overheating and burning any portion of the wire.

WEIGHT AND COST OF 1 SQUARE FOOT OF VARIOUS METALS 0.001 INCH THICK

Metal	Density		Weight		Cost of Metal	
	C.G.S.	British, Lb. per Cubic Foot	Lb.	Grammes	Price, Cents per Lb.	Cost, Cents
Aluminum	2.65	177	0.0148	6.62	25	0.372

Blanks indicate that experiments are not yet complete.

The outer jet performs a threefold purpose. It keeps the nozzles and wire cool, it cools the object and it produces the requisite velocity.

The velocity of the air leaving the jet will be independent of the volume discharged and depends only upon the pressure at the jet, so long as there is no disturbance due to entraining of air from the surrounding atmosphere.

In addition to this the air jet has to atomize the molten metal and accelerate the particles up to its own velocity, so that to perform this a certain mass of air is required.

As at present constructed the standard pistol uses about 0.55 to 0.6 cubic foot per minute for every 1 pound per square inch of air pressure, so that with an air supply at 80 pounds per square inch, which is a very suitable figure for ordinary spraying, the air consumption will be from 45 to 50 cubic feet per minute. The mass of this will be from 830 to 920 grammes, and the mass of metal sprayed by this air will be from about 8 grammes in the case of iron to about 200 grammes in the case of lead.

How effective the cooling is may be considered most readily shown by the fact that the hand can be held in the jet, so as to receive a coating of metal, without discomfort.

Adhesion Not Quite Explained

The action of deposition is probably a complex one. The minute particles of solid metal are driven with such force against the object that in some cases they fuse, but, owing to their small relative size, they are promptly chilled by the object to which they adhere. If any of the particles are molten or gaseous they will adhere. In addition, the suddenly chilled particles are possibly, or even probably, in the state of unstable equilibrium found in "Prince Rupert's Drops" and act like so many minute bombs bursting on impact into almost molecular dimensions and penetrating the smallest cracks and fissures of the object.

The process requires some care in manipulation, as by varying the conditions it is found possible to spray porous or non-porous coatings and, with some metals, anything from a pure metal to a pure oxide. With care, however, non-porous, oxide-free and adherent coatings can be produced of almost any metal on almost any solid.

In addition to the metals, it is possible to spray fusible

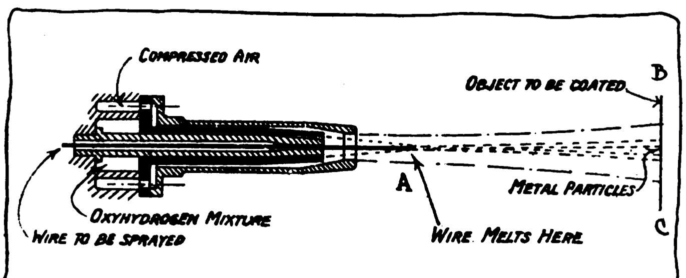

Fig. 2—Illustrating theory of cool and adherent deposits

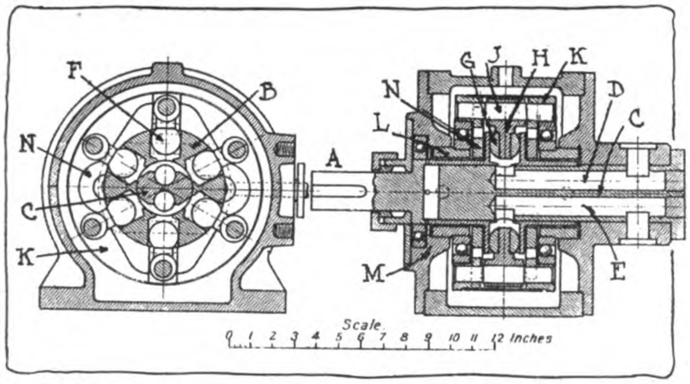

Fig. 3—Carey pump with variable stroke

non-metals or, by stranded wires, alloys of metals or mixtures of metals with non-metals.

Uses and Cost

The process is so new industrially that its uses are still partly to be developed. But it is easy to see that it may have far-reaching value for protective coatings against weather or fire, for ornament, for electrical resistance and conductors, for the production of special alloys [whether true alloys are formed does not seem to be decided as yet, however.—Ed.], for joint-making and for many other purposes.

Quite in a different category comes that of very fine casting. The surface of a pattern, polished or slightly greasy, is most minutely copied, and it is possible to produce electrotypes very rapidly. It may be useful to line molds before pouring in a metal. The application of the process to the production of very fine or coarse metallic powders is being investigated.

The costs of the process are not prohibitive and, even where higher than alternative processes, the great range and adaptability of the apparatus and its independence of muffles, pots, etc., may make it preferable. Some idea of the cost may be gained from the appended tables giving data on the three principal items; metal, gas and time.—From September bulletin of the Institute of Metals.

Main Features of an Oil Transmission with Variable Pump Stroke and Low Bearing Pressures

CAREY'S oil transmission system, which is brought out by Variable Pumps and Motors, Ltd., of England, resembles the Hele-Shaw hydraulic transmission by a radial arrangement of pumps which are worked with variable stroke by attaching the outer ends of the pistons to a ring susceptible of being adjusted to an eccentric relation to the axis of rotation, and in utilizing two channels in an axial shaft for intake and discharge of the fluid. The Carey variable transmission, as made for automobile purposes and for varying the speed and torque of propeller shafts in vessels, is based on the construction of the Carey variable capacity pump, the principal features of which are shown in Fig. 1. With the dimensions represented in this illustration this pump can absorb 20 horsepowers at 1,000 revolutions per minute, registering 1,500 pounds pressure per square inch.

The power shaft A drives the rotor body B in which the cylinder bores are drilled radially with ports to the central space of the rotor. Into the latter there is inserted from the opposite end the fixed shaft C with the two channels D and E, these channels communicating at their inner ends with the rotor ports by means of elongated ports in the tubular wall of the shaft, so that each channel at any time is connected with three of the rotor ports, as most clearly shown in the left portion of the illustration. Each piston, F, is composed of a steel ball G, fitting in the cylinders, to which is rigidly atached a phosphor bronze connector H, and the outer end of the latter is journaled upon a pin J extending laterally into bearings in two rings K which encircle the rotor and revolve on ball bearings carried by adjustable slides L working in grooves in the pump casing M. The slides are adjusted by rods passing through stuffing boxes in the casing. In Fig. 3 the slides are represented as working horizontally and the rods are not shown, but Fig. 4 shows them plainly.

When the rings are held concentrically with the rotor there is no reciprocating motion of the pistons but by pushing them to one side or the other the pumping action takes place, the direction of motion of the fluid depending upon the side where the axis of the rings is located, while the quantity of oil passed depends upon the distance from rotor axis to ring axis.

The rotary motion of the rings, concurrently with that of the rotor, is secured by means of projections upon the rotor and similar projections upon the rings, both entering slots cut at right angles to each other in plates N, the studs adjusting themselves to the eccentricity by sliding in the slots on the principle of an Oldham joint. The two rings carry between them on their outer circumference a thin steel drum which completely encloses the pistons and cylinders and separates the oil in the mechanism in an inner portion, which does the work, and an outer portion which obviates leakage and may be connected with a reserve. The revolving parts present a cylindrical smooth body rotating without paddle wheel action and with a minimum of friction in the outer oil with which the case is filled.

It is the mechanism just described which forms the driving portion of the Carey variable hydraulic transmission shown in Fig. 4, representing dimensions suitable for transmitting 30 horsepowers at 800 revolutions per minute. The variable stroke pump—with the handwheel for actuating the stroke adjustment—is arranged at one end of the casing, and a similar machine, in which the stroke is fixed, however, acts as a driven motor at the other end. Between them there is placed a phosphor bronze valve piece which serves as the valve face for both the pump and the motor, having parts cast through from one side to the other. It also contains two ball valves which allow any shortage of oil in either part to be replenished automatically by suction. In addition it contains a relief valve which is connected to whichever part hap-

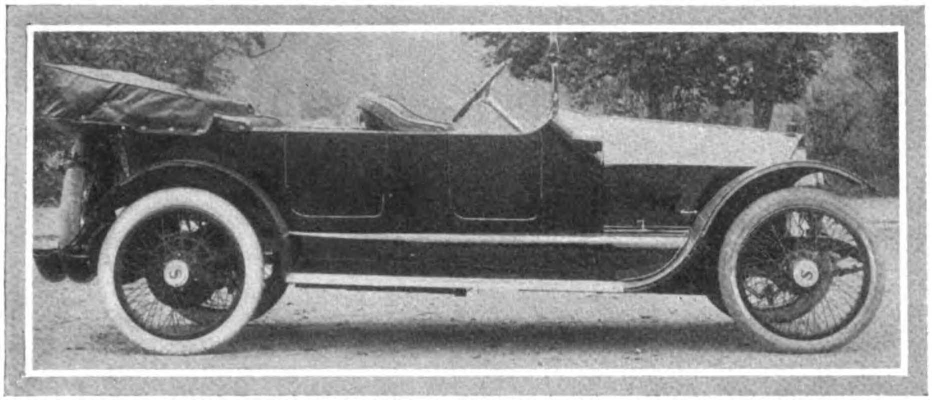
Unusual Manifolds on Singer Six



New Singer six with five-passenger body. The pointed radiator, clean running boards and smooth lines are features

Price $2,350—High-Powered-Motor—Cross-Head Pistons—Four-Speed Gearset—Spiral Bevel Axle

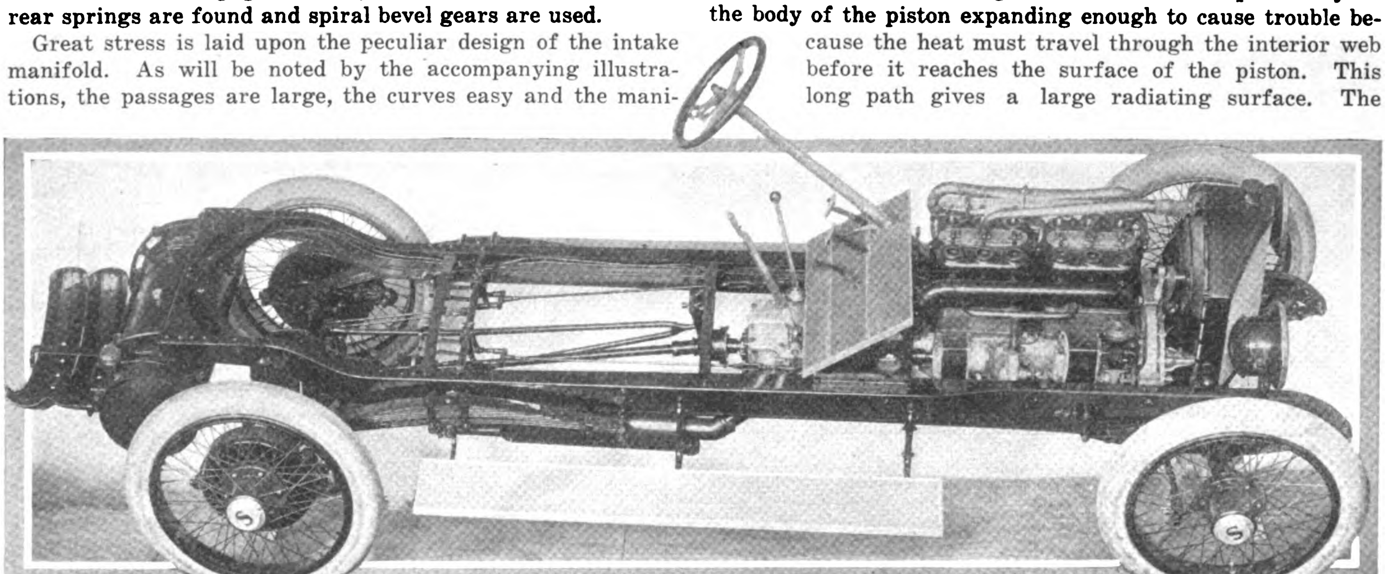
MANY features of unusual interest are incorporated in the six, for $2,350 just announced by the Singer Motor Co., Long Island City, N. Y. It is equipped with a 4 by 5.5-inch motor, dry-plate clutch and four-speed gearset with direct on fourth. These three parts are combined in a unit and suspended on three points. The motor is rated at 50 horsepower, but has developed in excess of 100 at speeds above 2,000 revolutions per minute. This power is sufficient to give the car, which is equipped with a five-passenger body, at a speed of better than 60 miles per hour and yet it is capable of ascending almost any hill on high gear—with a motor to wheel ratio of 3.66 to 1. The weight of the car is 3,800 pounds with all tanks filled and with full equipment. The wheelbase is 135 inches and the tires 36 by 4.5 inches. All cars will be sold directly from the factory to consumer—no dealers will be appointed. In fixing the price at $2,350 the dealer's profit has been given to the purchaser.

In telling of the features of this new car, the most important is the great power and flexibility of the motor which is obtained, it is said, by the use of unusual intake and exhaust manifold designs and the installation of a 1.75-inch C. R. G. carbureter. Cross-head pistons are notable in the motor, which follows usual practice otherwise. The drop arm of the steering gear is adjustable for wear, cantilever rear springs are found and spiral bevel gears are used.

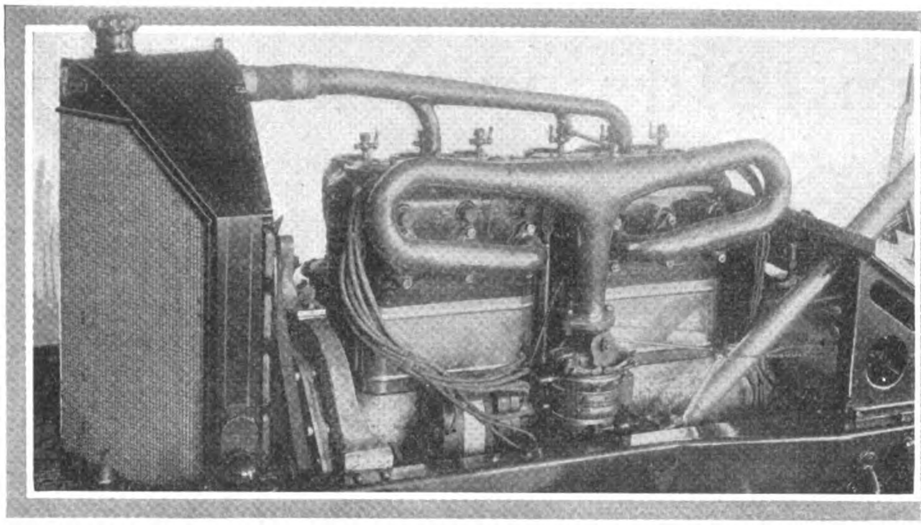
Great stress is laid upon the peculiar design of the intake manifold. As will be noted by the accompanying illustrations, the passages are large, the curves easy and the manifold as well as the carbureter is water-jacketed. The large diameter and the lack of sharp turns allows a good volumetric efficiency at high speed while the liberal water jacketing space prevents condensation and enables quick acceleration. Particles of gasoline that might condense on the walls are converted into vapor by the heat.

Difficulty due to two cylinders exhausting at the same time is overcome by the new exhaust manifold which gives a separate passageway to each set of three cylinders. The illustration shows the simplicity of this construction, there being a wall in the manifold which separates the flow of gas from the front pair of cylinders from that of the rear. The timing is arranged so that the exhausts of two cylinders in the same set are never open together, and therefore there is no interference between the cylinders. There is no danger of the exhaust from one cylinder just opening forcing gas back into another cylinder that has nearly finished this operation.

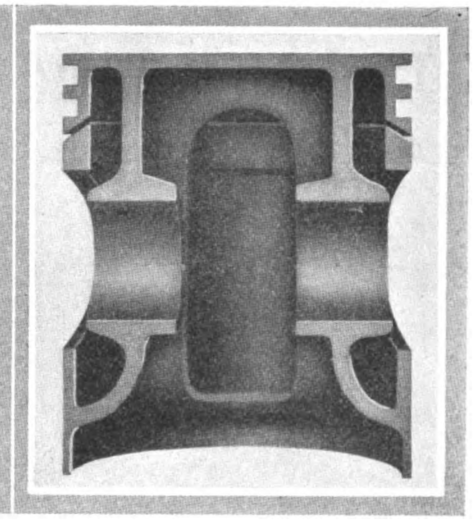
Easily the most important feature of the motor itself, which is a Herschell-Spillman, is the new cross-head piston in which the head, which is exposed to the heat, is practically separate from the trunk of the piston which takes the thrust of the connecting-rod. These two parts are held together by an interior web. The advantage of this design is that the upper part of the piston which carries the two rings, is made a comparatively loose fit while the trunk has only .001 inch clearance. The head can expand when exposed to intense heat without seizing and there is little possibility of the body of the piston expanding enough to cause trouble because the heat must travel through the interior web before it reaches the surface of the piston. This long path gives a large radiating surface. The



Chassis showing arrangement of units. The power tire pump, generator, water pump and starting motor are arranged on the right side of the motor. Note the cantilever spring and the triangular torque rod



Left side of motor showing peculiar intake manifold which is claimed to give increased power. The Y part of the manifold, as well as the carbureter, is water-jacketed to prevent condensation of the gasoline



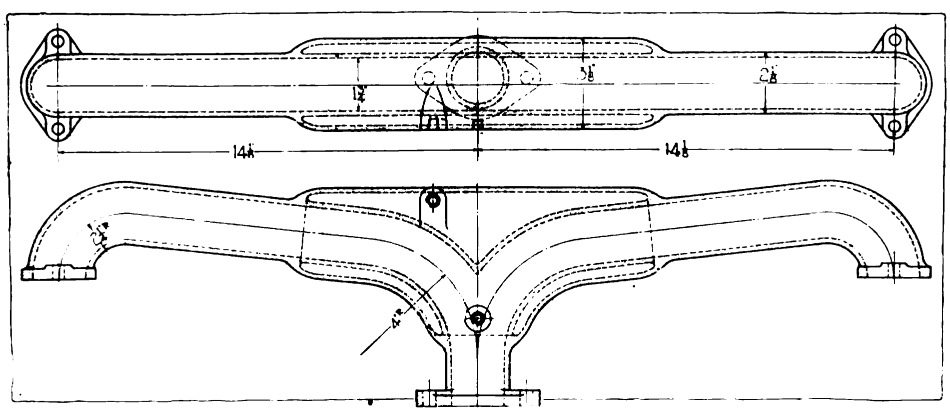
Cross-head piston in which the head is practically separate from the trunk. The head is exposed to heat but the trunk is not

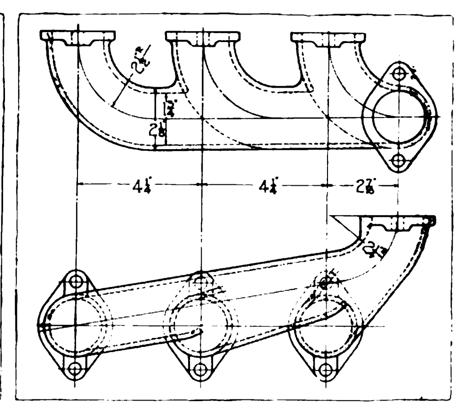
small clearance possible between the trunk of the piston and the cylinder is due to the piston ordinarily being cooler than the cylinder, with the result that it expands less rapidly and therefore there is no tendency for it to stick.

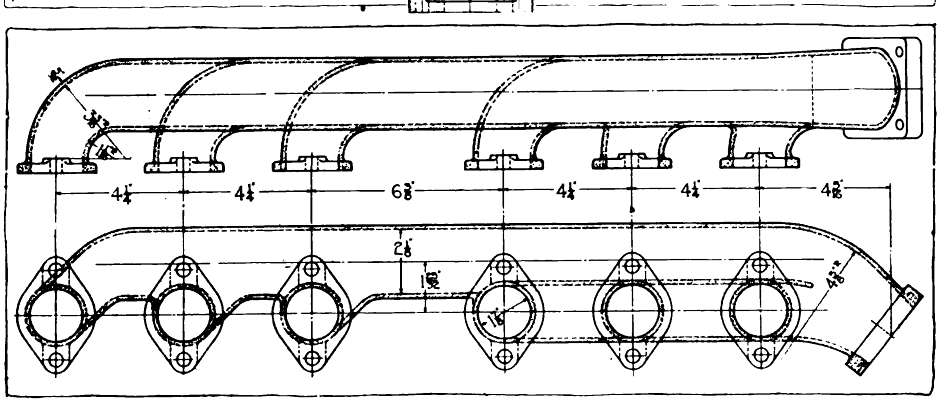
Of more than usual interest is the method of fastening the pitman arm or steering drop arm. The hub of the arm and the shaft on to which it fits have triangular slots milled into it lengthwise. The shaft is tapered so that adjustment may be made as wear occurs by slightly tightening the nut holding the arm in place, it being further on the shaft and thus held solid. This steering gear is manufactured by the Jackson-Church-Wilcox Co., Saginaw, Mich. It is a worm and nut type and is also featured by a 2-inch steering post and a 19-inch wheel with finger grips.

Smooth Body Surface

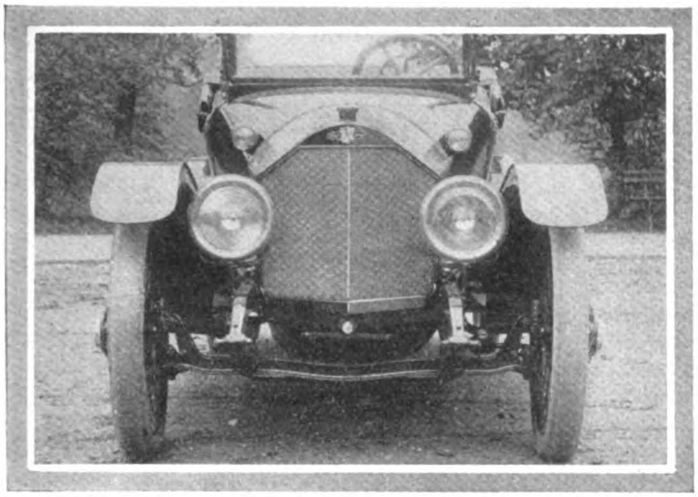
Unbroken body lines characterize the body design and unusually complete appointments are noted. The lines are accentuated by the use of a pointed radiator and slightly sloping hood. Left drive with center control is standard. The windshield is built into the cowl and is a combination rain-vision and break-down type. All instruments are mounted flush on the cowl board. At the extreme left is the primer which consists of a plunger pump which acts on a ball valve and sends gasoline to the throat of the manifold to insure easy starting. Next there is a 100-mile Warner speedometer of standard construction with a small electric light to illuminate it at night. This device is driven from the rear of the gearset. There is a Westinghouse voltmeter and adjacent to this a fuel pump provided with a blow-off. In the center is the switch and coil, which forms part of the Eisemann dual system. A gasoline pressure gauge is provided and this should register about 2 pounds. Next to this is an 8-day clock that is wound through the rim. An oil gauge shows the pressure in the lubricating system and should ordinarily register between 3 and 6 pounds depend-



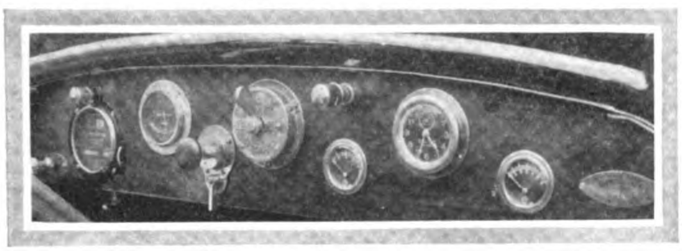




Upper—Left—Intake manifold showing water jackets. Upper—Right—Portion of intake manifold which bolts to cylinders. This manifold construction differs in detail from that shown in the illustration of the motor. Lower—Left—Exhaust manifold showing partition which separates the two cylinder sets



Front of car showing pointed radiator



Arrangement of instruments on cowl board

ing on the temperature and also on the speed of the motor.

At the right, there is a light which illuminates one-half of the instrument board and at the same time it can be removed and used as a trouble lamp, being provided with 10 feet of cord for this purpose. A Pyrene fire extinguisher is placed to the right of the cowl.

Just under the front cushion of the driver's seat is the lighting switch. It is a three-gang type providing for the lighting of the side and tail lights, head and tail lights and for controlling the dash lights separately.

A one-hand top made by the Pantasote company and covered with the highest grade of pantasote is fitted. The front of the top fastens directly to the windshield by means of ball catches that eliminate the need for straps, or other fastenings. Jiffy curtains are included in the equipment. An interesting detail is the use of a flap on the back of the front seat to prevent this panel from being foot marked. Slip covers are fitted as well as the usual robe and foot rail.

At the rear there is a substantial carrier for two spare tires, and license brackets are installed at the front and rear.

Concealed hinges and door latches are used and the running and floor boards are covered with corrugated linoleum. The squeaking of the body is prevented by mounting it on lead strips.

The motor is a T-head design with the cylinders cast in two blocks of three. The valves are inclosed. The carbureter and magneto are mounted on the left, the latter being an Eisemann high-tension design, designated as model E M I R 6. The high-tension wires to the spark plugs are carried in an aluminum conduit. On the right side there are four motor accessories, the power tire pump, generator, water pump, and starting motor being arranged in this order from front to rear. The first three are driven from the same shaft while the starter turns the motor by a pinion meshing directly with teeth cut in the flywheel. The electric units are of Westinghouse make, and the single-wire system is used, but the electric light bulbs throughout the car are of the double wire type because it is easier to obtain these in out-of-the-way places than the single wire type. The return wire from each light is grounded. All wires are encased in flexible metal conduits. Starting current is furnished by an LBA, S L B 610 storage battery, capacity being ampere 110 hours and the voltage 6. The battery is placed under the right front seat where it is easily accessible when water is added or specific gravity readings taken. The left compartment is for tools.

To insure silence of operation the couplings at either side of the pump are leather while the connection between starter armature and the driving pinion is by an Oldham coupling.

Cooling is accomplished by a V-type El Arco radiator which holds about 5 gallons. Water circulation is maintained by a centrifugal pump of large size and the circulation of air is aided by a five-bladed fan which is belt-driven. Adjustment for slack in the belt is provided for by a vertical slot in the bracket that carries the fan.

Three Point Suspension

As already stated, the power plant is suspended on three points, one at the front and two at the rear of the motor. The front support consists of an arched cross-member of inverted U-section, a bolt at the center of it carrying the motor. At the rear there are two arms extending from the crankcase.

Lubrication is a combination of the splash and force feed methods, there being a gear pump to maintain a circulation of oil and sump in the bottom of the crankcase that holds approximately 1 gallon. Plain bearings are used throughout the motor. Both crank and camshaft are supported on three bearings and the cam followers are the mushroom type. A combined oil filler and breather is located on the left side between the cylinder sets. It is provided with a sight glass and a float to show the level of oil in the crankcase.

Power is transmitted from the motor to the gearset through a dry plate clutch consisting of thirteen steel disks faced with fiber. A double helical spring supplies the pressure for engagement. A simple clutch brake is provided in the form of a fiber plate against which the clutch collar presses.

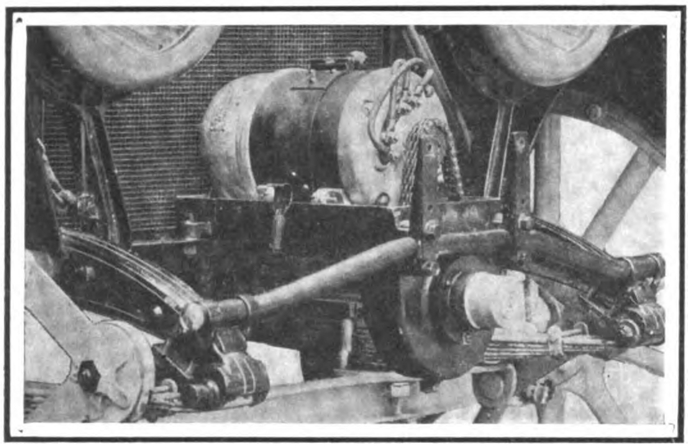
A North East System for All Old Cars

Motor-Generator Unit Replaces Crank Handle at Front of Car—Both 12- and 24-Volt Systems Offered



Mounting of North East generator showing method of clamping the cross member to the frame

A STARTING and lighting system that is easily installed on almost every make of automobile has been perfected by the North East Electric Co., Rochester, N. Y. The starting motor and lighting generator are combined in a single unit which is mounted in front of the radiator, the drive being by silent chain to the front end of the crankshaft, at the point at which the starter crank ordinarily attaches. This system is identical with the other systems built by this company for several years past, except that it is designed for mounting on any make of car. It is furnished both in 12 and 24-volt styles. A storage battery, which can be mounted on the running board or in the body, is furnished with the system.

Placed Between Frame Members

The motor-generator unit is mounted between the front frame members by means of two cross bars. The rear bar is an angle iron which is bolted at each end to the webs of the channel frame section by means of small angles. In the front the unit is supported by a heavy tube which is clamped to the horns of the springs. This member may be bent to bring it to the required height.

The armature runs at approximately 2.66 crankshaft speed, the reduction being obtained, as already noted, by the use of a silent chain. The motor-generator unit is placed above the plane of the crankshaft and as the driving chain is at the front, the shaft which runs to the crankshaft passes under the unit. This shaft has long flutes milled in it and it may be cut off to the length desired. The coupling which makes connection between this shaft and the front of the crankshaft is left blank and is machined to suit each particular installation.

Accessibility a Feature

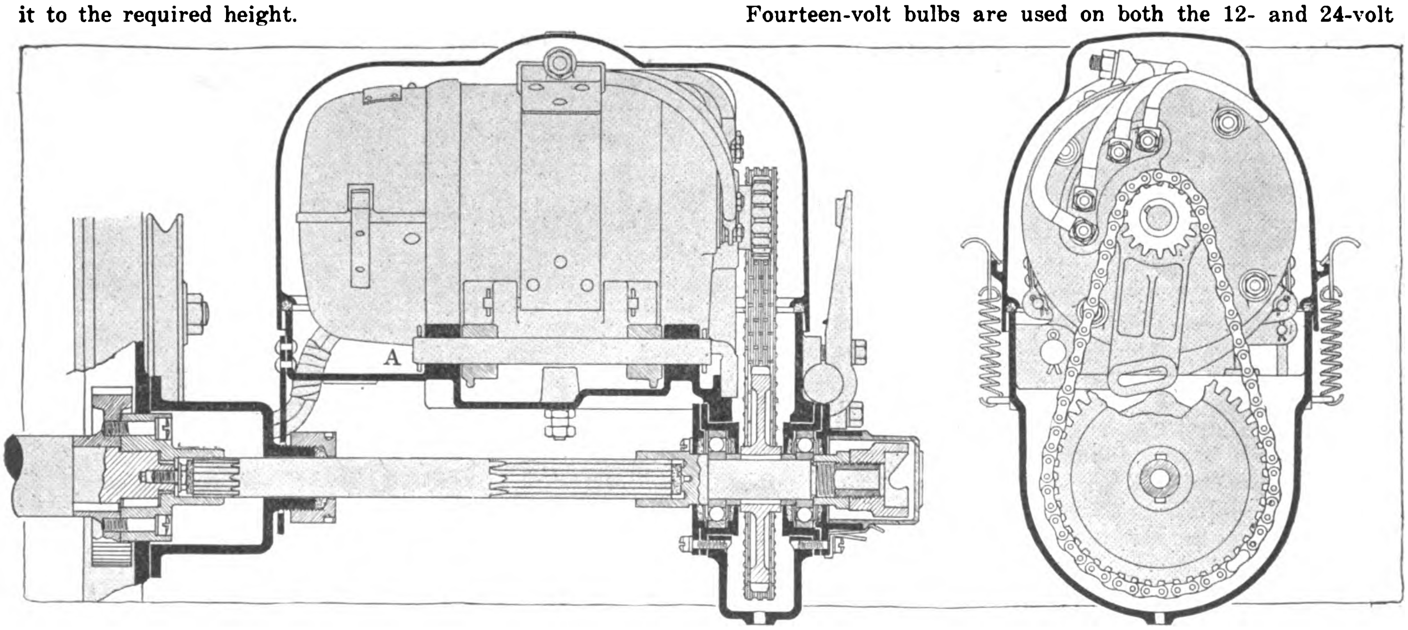
The position of the starter has several advantages: It is easily accessible for adjustments, inspection or repairs and it does not interfere with the accessibility of any of the motor parts. There is little objection to this position as far as the appearance is concerned because the unit is ordinarily covered with the front number plate, as illustrated, brackets being provided for the attachment of the plate.

The unit is suitably protected from the weather by a sheet metal case which may, however, be instantly removed. Adjustment of the driving chain is obtained by swinging the generator about the point A, in the accompanying line drawing, where it is pivoted. There is an adjusting screw for this purpose.

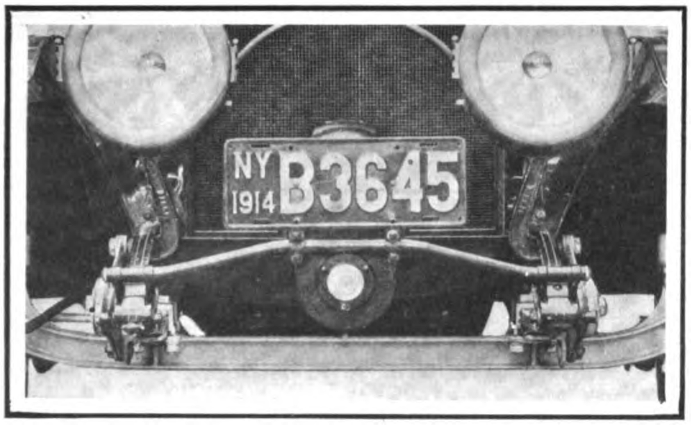
Armature Only Moving Part

Only one moving part is found in the unit, and that is the armature which is mounted on annular ball bearings. No mechanical governor is used. The brush construction is especially for automobile work and the brushes are manufactured from a material having high conductivity and long life. All coils are treated with an oil and moisture-proof compound. The materials give the maximum amount of strength with a minimum amount of weight, it is said.

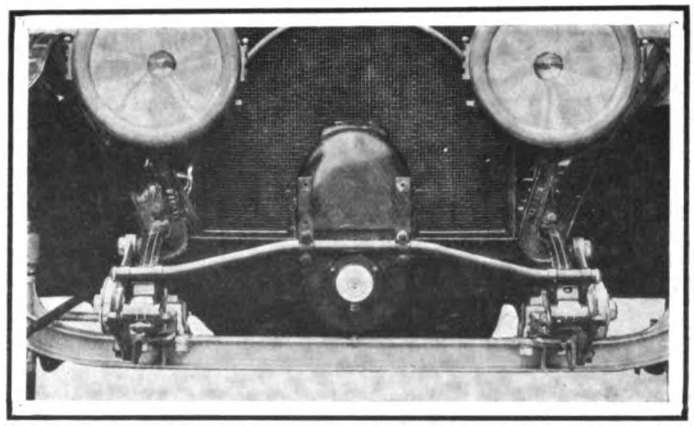
Fourteen-volt bulbs are used on both the 12- and 24-volt



North East starting and lighting unit. At the left the mounting of the unit is illustrated, the driving chain and gears are shown, and the construction of the main shaft given. The right view shows the front end and illustrates the driving gear mechanism. The long splines in one end of the driving shaft permit it to be cut to any desired length



Appearance of North East motor-generator unit before the attachment of the license tag



North East generator almost completely concealed by the license tag. Brackets are provided for its attachment

systems throughout. The head lamps are 21 candlepower, the side lamps 4-candlepower and the tail lamp is also 4-candlepower. Bayonet bases are found throughout. The wiring is extremely simple. Two wires run straight from the battery to the motor-generator unit. To these leads the various lighting wires are attached, while the wires running to the starting switch are on a separate circuit.

A full line of accessories are manufactured to go with the starting and lighting system. These include torpedo headlights finished in japan and brass or japan and nickel, and side and tail lights similarly shaped, and finished. Two types of dashlights are made; one for flush mounting and the other with a ball and socket mounting. In addition a flush type voltmeter showing the condition of the battery, whether charged, or discharged, is offered and a hydrometer syringe for testing the specific gravity of the electrolyte completes the line.

Attachment Is Simple

The installation of the North East system is simple, and can be accomplished at very little expense. The first step is to remove the timing gear cover, and then the dimensions of the end of the crankshaft are taken and the coupling is machined to fit over this end. The large end of the coupling is left soft so that it may be machined without difficulty. When mounting this clutch member it is important that there is sufficient fastening for the keys and bolts so that no trouble will appear from this part coming loose.

If it is necessary to shorten the driving shaft a piece is cut from the end having the long splines. As this shaft is hardened on the surface, however, it is first necessary to grind through this hard surface, after which the remainder of the section may be cut with a saw. The end is then squared up by grinding. If this shaft is too long, damage to the bearings will result.

Starting Switch Near Motor

The starting switch is mounted near the front of the motor and as closely to the motor generator as convenient in order to have the wires as short as possible to cut down resistance losses. The starting button is located on the footboards and the cable running to the switch so adjusted that there is no slack when the button and the switch arm are in their normal positions. Where the run of cable is longer than usual it is advisable to support it in one or two places.

If the car is fitted with oil lamps, side and rear, and gas head lamps, these may be transformed by mounting reflectors in the head lamps and adapters in the side and tail lamps. In case the car is fitted with electric lights, a very careful inspection of the connections and the lamp sockets should be made to see that they are in good order and then the bulbs should be replaced with the standard 14-volt type used with this system.

More Cars, Fewer Horses in Milwaukee

MILWAUKEE, WIS., Oct. 13—According to Tax Commissioner Arnold of this city the number of automobiles owned here is 5,943 as against 4,744 in 1913, there being thus a gain of 1,199 cars within 12 months.

During the same period the number of horses, mules and asses decreased by 193, the total being 11,032, instead of 11,225 last year. While in 1913 the number of cars owned was only a trifle over one-third the number of horses, this year there are more than half the number of automobiles than horses.

The personal property record for 1914 shows a total of $91,348,240, of which $3,791,535 is credited to automobiles, $86,870 to other motor vehicles, $1,189,885 to horses, mules, asses, $568,830 to wagons, carriages, sleighs.

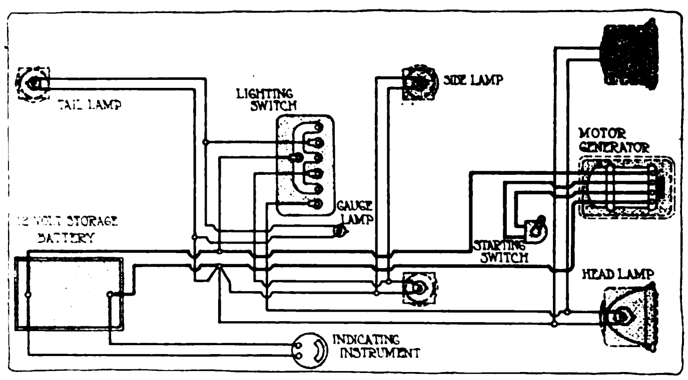


Diagram of 12-volt system. Two leads run from the battery to the motor-generator unit. From those two leads wires branch off to the various lamp circuits. The starting switch is on a separate circuit

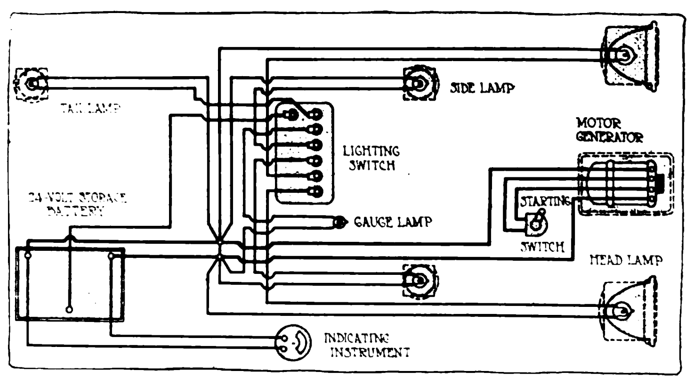

Diagram of 24-volt system. In this system, also, there are two main wires from the motor-generator to the storage battery, and the lamp wires branch off from these two main leads, but in this case each pair of lamps is put in series due to the use of twice the voltage with the same type of lamps

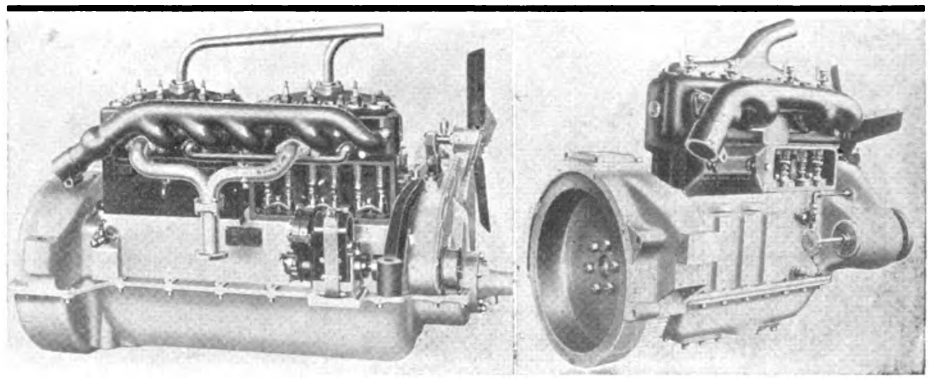
Four and Six Comprise 1915 Davis Line

Four Is Compromise Size Between Two Previous Models—$100 Cheaper—New Streamline Bodies



Left—Six-cylinder motor used in 1915 Davis. Right—Four-cylinder engine used in new Davis with one valve cover plate removed

FOR 1915 the Davis line, manufactured by the George W. Davis Motor Car Co., Richmond, Ind. has been considerably revamped. In 1914 it consisted of a six and two fours. For 1915 there will be one four, a compromise size between its predecessors, and a continuation of the six.

While all the details of the six have not as yet been fully decided, the chassis will be practically the same as before and, as regards the body, it will be offered in five- and six-passenger styles at $2,150 for the five and $2,185 for the six-passenger. This is the same as last year, but the bodies are entirely new.

For 1914 the Davis fours were respectively 3.5 by 5 and 3.75 by 5.25 inches. For 1915 the four will be 3.75 by 5. Outside of the change in dimensions, however, the motor resembles very much the smaller four of 1914 in that it is a Continental unit power plant with three-point suspension and block-cast L-head cylinders.

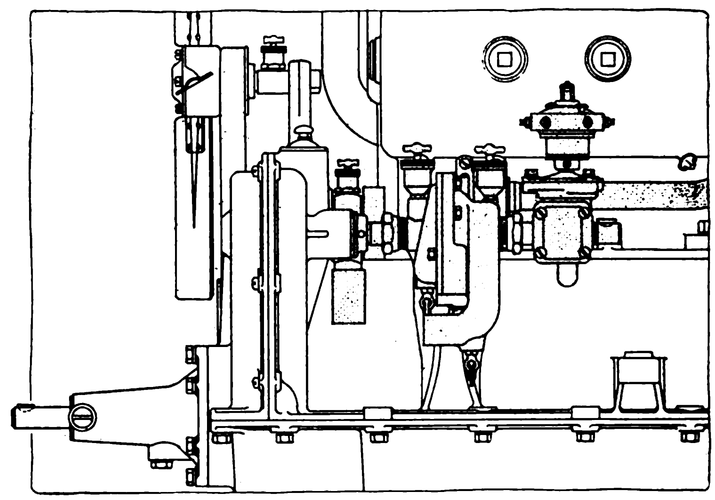
Besides bringing the line down to a two-chassis basis and bringing the bodies up to the latest dictates of streamline fashion, the Davis company has made few alterations in the cars themselves. The bodies, in fact, have been kept up to date by giving them the prevailing molded form, eliminating the side lamps and amplifying the dash equipment.

Bendix Gear for Starter

The changing of the instrument board has been rendered possible by an alteration in the starting and lighting outfit. This is the incorporation in the Westinghouse ignition-lighting unit of the coil. The coil used to be on the dash, now it is under the hood with the generator. Another change in the Westinghouse apparatus, which is used for starting as well as lighting, is the use of the Bendix gear for the engagement of the cranking motor to the engine.

The Bendix gear is an ingenious arrangement in which the drive pinion on the cranking motor is carried loosely on the armature shaft of the motor, being free to travel in a spiral groove with which it engages on that shaft. The loose pinion carries a pendulum and when the armature of the starting motor revolves, the gear is held from revolving with it by the weight of the pendulum. Consequently, the pinion travels along the shaft until it engages with the gear on the flywheel. At this point it has to revolve with the shaft of the cranking motor and thus spins the engine. As soon as the latter starts under its own power the gear is thrown off by the centrifugal force of the pendulum and with the opening of the switch the starting motor is thrown out of action.

Although the unit power plant construction has been maintained without change, a shift has been made from the disk to the cone clutch in the four. This has been effected without a change of housing as is provided in the Continental engine.



Water pump arrangement on six-cylinder Davis motor. Thermo-syphon cooling is used on the four

Another change is in the fuel feed. This was formerly by pressure but since the tank is located beneath the front seat, gravity has been deemed a sufficient method of bringing the fuel to the carbureter.

Thermo-syphon cooling is still used on the four but the new rounded vertical tube radiator adds more cooling surface. A new carbureter, which the Davis engineers state will produce a notable gain in economy, has been adopted. This is the Stromberg, Model K.

Price $100 Lower Than for 1914

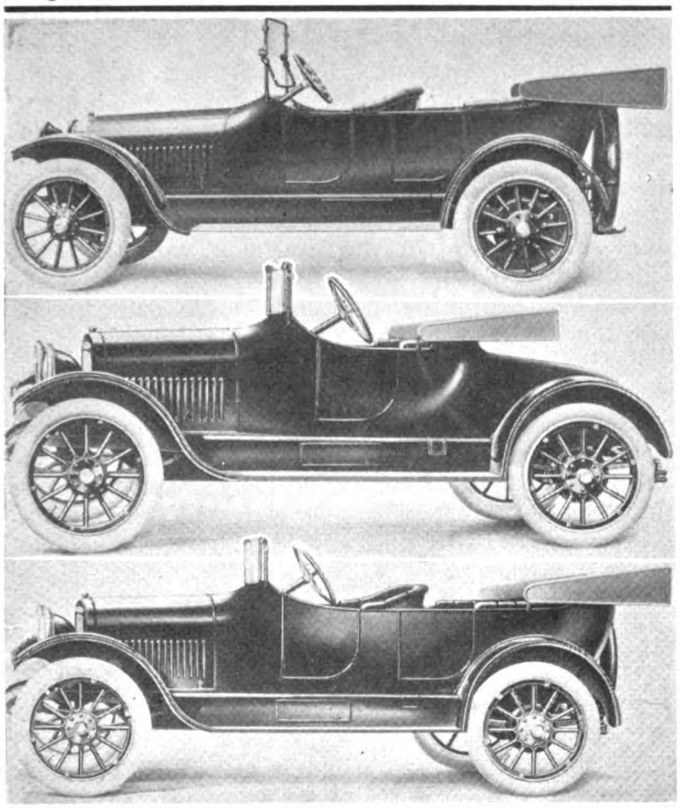
No changes are found in the drive members or in the rear axle, but the wheels are larger and now carry 34 by 4 tires, whereas the previous small four of which this is the outgrowth had 33 by 4. All around, it is a larger car of up-to-date design for less money. The car sells for $1,235 fully equipped in touring or roadster body. This is a reduction of $100 as compared to the smaller four of last season.

The power plant used in the four is the Continental W. It is a block motor with L-head cylinders, suspended at three points and providing a unit plant. The bore of 3.75 and stroke of 5 inches provides a horsepower rating of 22.25, but as the stroke bore ratio is 1.33, this rating is considered very conservative.

Three rings are used on the pistons and conventional practice is followed in regard to I-beam connecting-rods with wide bearings. The crankshaft is of .40 carbon steel analysis.

The disk clutch and gearbox are housed in the same unit, as the crankcase of this motor is carried back past the flywheel ending in a broad face to which the gearset housing is bolted. The gearbox is a Warner three-speed design. The gears in this set are designed for maximum toughness, having a chrome-vanadium composition.

The driveshaft is inclosed in a torsion tube, but the drive is transmitted to the car by way of the rear springs. The rear axles are Weston-Motts, three-quarter floating. A feature of these axles is the ease of adjustment that can be effected on the mesh between the drive pinion and the large bevel gear.



Upper—Six-cylinder Davis five-passenger touring car for 1915 selling at $2,150. Note streamline form and absence of dash lamps. Middle—Four-passenger, two-cylinder roadster type. Lower—Four-cylinder, five-passenger touring car which sells for $1,235

The frame construction is such that a straight taper is given. The springs are Sheldon products, being 2 inches in width and of platform construction in the rear.

A full line of equipment is supplied. The Westinghouse two-unit lighting, starting and ignition is provided. It is a 6-volt job with the lighting and ignition generator in a unit with the step-up coil for high-tension ignition. The distributer is also a unit with the generator. This unit is mounted on the right of the motor. The battery is a Willard. The wheelbase of this car is 112 inches.

Few Changes in Six—New Bodies

The power plant and chassis of the six remains practically the same as for 1914, although parts of the electric equipment have not as yet been determined, and deliveries will not start on the remodeled body until November.

The six L-head cylinders are cast in threes, and have a bore and stroke of 3.75 by 5.25 inches. This is the Continental Six P type. The motor has a three-bearing crankshaft of 90,000 pounds tensile strength. The bearing diameters are respectively 2, 2.25 and 2 inches for the front, center and rear. When finish ground the crankpins have a diameter of 1.875 inches.

The pistons are three-ringed with pins having a bearing length of 1 7-32 by 1 7-8 inches. Connecting-rods are drop-forged I-beams of .40 carbon steel and the caps on the lower bearing are held by nickel-steel bolts.

All valves are inclosed and are on the right side, being driven by a 1 1-16 inch diameter camshaft having three bearings. The timing gears are helical.

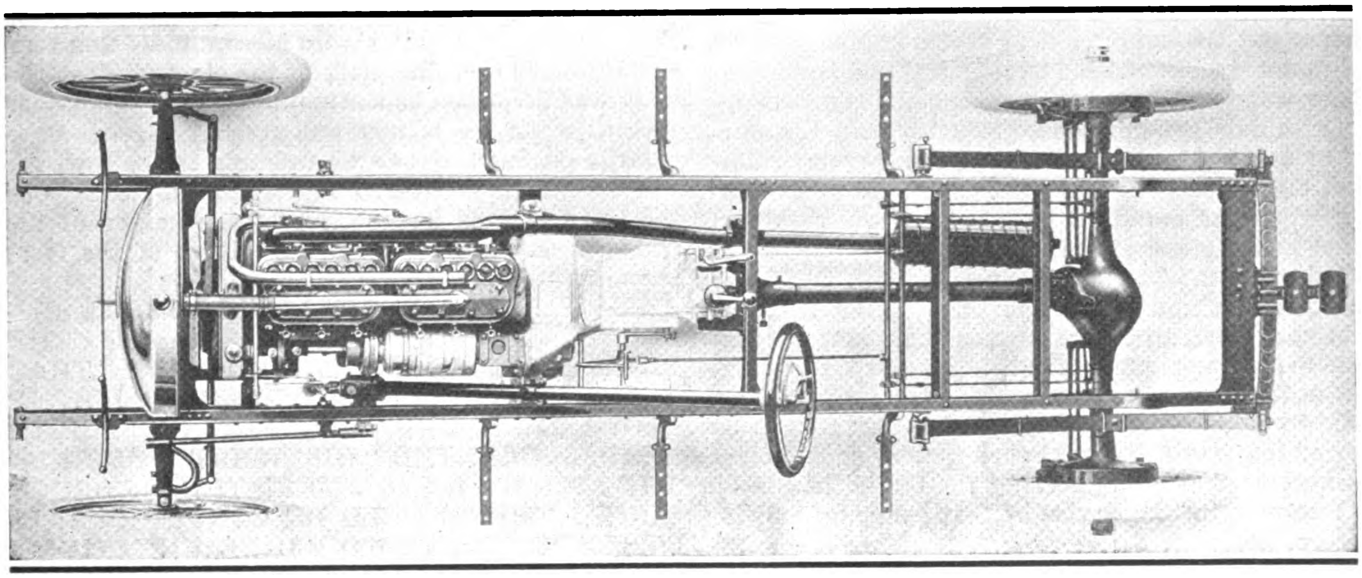
Ignition will be taken care of by a Bosch dual system, the battery end of it being taken care of by a Willard installation. The carbureter is the Stromberg G.

Pump Water Circulation

On this car, pump water circulation is used. Another point of difference between this and the four is the use of a disk clutch and Warner four-speed gearbox.

The rear axle is floating. Left drive and center control, 37 by 4.5 inch tires and a 128-inch wheelbase are features of the chassis.

The new bodies on this car are full streamline effects without a break. Full equipment is sold with the car. The prices on this are $2,150 for the five-passenger and $2,185 for the six-passenger.



Plan view of six-cylinder Davis chassis showing left drive and center control and mounting of Westinghouse starting system at the left of the motor. Note platform rear spring, and extra tire bracket

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Traffic Engineering

LAST week's "get together" convention of a score or more of motor truck makers emphasized the old problem of selling motor trucks and incidentally drove home once more the argument that traffic engineering is daily becoming a greater factor in the selling of trucks.

Three years ago when one of our industrial engineers put the expression of traffic engineering on the motor truck salesmanship map, the traffic engineer was some form of superior personage occupying a middle ground somewhere between the purchaser and the maker. He was not a regular salesman, but a specialist who was called into consultation when the standard proposals of the salesman failed to bring conviction to the buyer.

Today the movement, as expressed last week, has gone further, and now traffic engineering is, or at least should be, an asset of every salesman, who expects to continue in merchandising power transportation in the form of motor trucks. The proposal was made by one of the speakers, and it deserves to be carried into execution, that each factory should open a school on traffic engineering for the education of all salesmen in the service of that company and its dealers.

This is a bold conception and a commendable one. It has but one mission, namely, actually selling motor trucks, in contrast with trying to dispose of them whether they best meet the requirements of the buyer or not.

The establishment of such a school pre-supposes the fact that to date many trucks have been sold that are not well suited to the field of work they have been placed in. There is one result that can follow such a condition—the truck does not work to its maximum capacity, its efficiency factor is too low, the purchaser is not satisfied.

What would you think of a garageman who in order to do his regular line of repair work bought an immense factory lathe, one only intended for special lines of work in a large factory. It would be a very poor investment. But we meet with such absurdities in the truck field. Today you find a merchant with a 3-ton truck when a 1500-pound vehicle would better meet his requirements. Perhaps the salesman was to blame in his anxiety to make a sale.

Traffic engineering, even in its simplest elements, would in the mind of the salesman work against such ill-advised sales, sales which though satisfactory at the beginning will end in disappointment when the buyer becomes aware of his folly.

The day of traffic engineering school in every factory will be welcomed if it will do nothing more than give salesmen the proper perspective of the field of truck operation, so that they will not err in selling to a merchant a type of vehicle entirely unsuited to his field. Better that such a sale were not made, than that it stand to bring discredit later upon the vehicle and its maker.

The Streamline Concept

NO term in the automobile world has been more abused than the expression "streamline." Three years ago when it came on the horizon, in its application to certain aspects of body lines, its misuse began and it has increased ever since in direct proportion to the number of concerns manufacturing bodies that they imagine come under this classification.

The term is misused, largely due to ignorance of the true meaning of the word streamline. One year ago if a cowl took the place of the straight dash the body was described as a streamline one. In another factory when the bonnet was given a flare so as to enlarge gradually from the radiator to the cowl the word streamline covered the situation. This year the word is used irrespective of the nature of the body curves, and for 1915 the misuse of the term promises to be as general.

THE WORD "STREAMLINE" FROM ITS SIMPLEST MEANING SUGGESTS THAT THE LINES MUST BE SIMILAR TO THOSE THAT A STREAM OF WATER WOULD FOLLOW IF FLOWING AROUND AN OBJECT OF SIMILAR SHAPE. GRANTED THIS, WHAT WOULD BE THE FIRST CHARACTERISTIC OF SUCH LINES? THEY WOULD BE CONTINUOUS; IN OTHER WORDS IT WOULD BE UNNATURAL TO HAVE LINES SUCH AS TO SET UP EDDY CURRENTS, OR MINIATURE WHIRLPOOLS

AROUND DIFFERENT PARTS OF THE BODY.

A final test of the streamline conception might be carried out imaginatively if a body were placed in a current of water with the radiator end pointing up stream. Observe if the water flows regularly along the side lines from front to rear. Does it adhere closely, or are there curves which tend to throw the water off, away from the body, and before it returns to the body little eddies are set up.

SUCH AN IMAGINARY TEST REVEALS NOT A FEW ESSENTIALS OF STREAMLINE DESIGN. TO BEGIN: THERE MUST NOT BE ANY CURVE THAT LEADS THE EYE AWAY FROM THE BODY LINES IN REAR OF THAT CURVE; RATHER EACH CURVE SHOULD LEAD THE EYE INTO THE BODY FURTHER BACK.

Apply this test to any body you desire. Does the curve at the cowl lead the eye away from the body and direct it upwards, if so the streamline ideal has been violated, the curve is exactly the reverse of the true streamline one.

In streamline formations the front end is invariably the largest and there is a general tapering towards the rear. The fastest fishes, those capable of sustained speeds of nearly 60 miles per hour, are fashioned true to this conception of the streamline. The largest diameter of the body is much closer to the head than to the tail. Observe such mammals swimming and there is not a place on the entire body where a curve tends to lead out of the body, but rather each curve is formed to lead into the body—it is in short an unbroken line from the tip of the nose to the end of the tail. This is the true streamline conception.

VanDervoort Nominated for S. A. E. President

NEW YORK CITY, Oct. 12—W. H. VanDervoort, president of the Moline Automobile Co., has been nominated for the presidency of the Society of Automobile Engineers for next year by the Nominating Committee, and to succeed Henry L. Leland, who has occupied this post during the present year. Mr. VanDervoort has had wide experience that should qualify him for this post. In addition to his experience as a manufacturer, he was, previous to his connection with the motor car industry, a professor in the University of Illinois.

The complete list of officers nominated follows:

President......W. H. VanDervoort	Second Vice-Pres...Jos. A. Anglada
First Vice-Pres. Frederick R. Hutton	Treasurer ....A. B. Cumner

COUNSELLORS

C. B. Rose.................1915-16	W. P. Kennedy............1915 16
John Wilkinson 1915-16	Frank M. Germane.........1915

Frederick R. Hutton, familiarly known as Prof. Hutton, is associated with the testing laboratory of the Automobile Club of America. Jos. A. Anglada has been a member of the counsel for 2 years, and is a consulting engineer in New York. A. B. Cumner, consulting engineer, New York, is nominated to take the place which has been held by Hermann Cuntz for a number of years.

Packard Surplus is $1,797,820.42

DETROIT, MICH., Oct. 14—The Packard Motor Car Co. in its annual statement issued today shows a surplus of $1,797,820.42. This is $600,000 greater than the surplus for the previous year. This surplus remained after deducting for plant depreciation, paying all expenses of the business and interest on debenture notes or setting aside proper reserves to cover the same and after paying the regular dividends on the preferred stock and a special distribution of the common stock of the company.

During the fiscal year 3,612 vehicles of all types, including passenger and commercial types, were manufactured.

Australian Imports Decrease 8% in 1913

NEW YORK CITY, Oct. 10—At the request of the Motor Traders' Assn. of New South Wales, the Federal Dept. of Trade and Customs has compiled a return of motor-vehicle importations into Australia for the calendar year 1913. A comparison with similar figures for 1912 shows a falling off in chassis imports of 8 per cent., the amounts expended for the respective years being: 1912, $7,063,700; 1913, $6,489,722. Every state with the exception of Tasmania, which gained 32 per cent., lost ground in chassis importations during the year under review. Body imports also declined, the decrease in 1913 as compared with 1912 being $43,488, or about 4 per cent.

The combined chassis imports from the United States and Canada substantially exceeded those from the United Kingdom. This is the first time on record that this has happened, and denotes the great demand for the cheap, light car, to which the American and Canadian manufacturers pay special attention.

Details of the imports into the Commonwealth are given in the accompanying table.

CHASSIS FOR MOTOR CARS (NOT INCLUDING RUBBER TIRES, LORRIES AND WAGONS).

Imported from—	New South Wales	Victoria	Queensland	South Australia	Western Australia	Tasmania	Commonwealth
United States	$645,787	$394,533	$301,277	$167,330	$102,211	$29,914	$1,641,052

372 Companies Allotted Space for National Shows

New York Has 188 and Chicago 184—Ninety-five Car Exhibitors for New York—Five Electrics—Chicago Has Ninety-six, with Seven Electrics

NEW YORK CITY, Oct. 12—Final allotments of space for the automobile shows at this city, on January 2-9, and at Chicago, January 23-30, were made on October 8. A total of 372 companies received space allotments for the two shows, New York leading with 188 and Chicago with 184, as compared with 353 in 1913, with 183 for New York and 170 for Chicago.

There will be ninety-five passenger car exhibitors at New York City, divided up into ninety gasoline and five electric car companies, while Chicago will have ninety-six passenger car exhibitors, with seven of these being electric car exhibitors. Seventy-four of these are N. A. C. C. members.

Last year there were seventy-nine car exhibitors at New York and sixty-five at Chicago.

There will be ninety-three accessory exhibitors at this city and eighty-eight at Chicago. Last year there were 104 at this city and 105 at Chicago. This decrease is due to the tire, axle and ball bearing people's refusal to exhibit this year. Only two of these concerns have expressed their desire to exhibit and they are the Bock Bearing Co., Toledo, O., maker of roller bearings, and the Bearing Co. of America, Lancaster, Pa., maker of ball bearings and universal joints.

Those companies which are exhibiting for the first time at the shows are the American Cyclecar Co., Detroit, Mich.; Argo Motor Co., Jackson, Mich.; Cresson-Morris Co., Philadelphia, Pa.; Durant Dort Carriage Co., Flint, Mich.; Enger Motor Car Co., Cincinnati, O.; L. P. C. Motor Car Co., Racine, Wis.; Cowles-MacDowell Pneumobile Co., Chicago, Ill.; Milburn Wagon Co., Toledo, O.; W. A. Paterson Co., Flint, Mich.; Sphinx Motor Car Co., York, Pa.; Remington Motor Co., Rahway, N. J., Crawford Automobile Co., Hagerstown, Md.; Entz Motor Car Corp., New York City; Scripps-Booth Co., Detroit, Mich., and the Pilot Motor Car Co., Richmond, Va.

Those companies exhibiting at last year's show which will not be present this year are the following: Pope Mfg. Co., Hartford, Conn.; American Motors Co., Indianapolis, Ind.; Palmer-Singer Mfg. Co., Long Island City; Simplex Automobile Co., New York City; Thomas-Howard Co., Jackson, Mich.; Vaughan Car Co., Kingston, N. Y.; Norwalk Motor Car Co., Martinsburgh, W. Va., and the Selden Motor Vehicle Co., Rochester, N. Y.

In the drawing for space the first choice fell to the Overland, followed by Studebaker, Buick, Cadillac, Chalmers, Hudson, Packard, Maxwell, Hupp, Reo, Oakland, Pierce, Paige-Detroit, White, Jeffery, Cole and Locomobile. The complete order of drawing is given at the end of this article.

Exhibitors at New York and Chicago Automobile Shows

Abbott Motor Co.............Detroit, Mich.
American Electric Car Co......Chicago, Ill.
Anderson Electric Car Co......Detroit, Mich.
Apperson Bros. Automobile Co.Kokomo, Ind.
Auburn Automobile Co........Auburn, Ind.
Austin Automobile Co..Grand Rapids, Mich.
Baker Motor Vehicle Co....Cleveland, Ohio
Briggs-Detroiter Co. ....Detroit, Mich.
Briscoe Motor Co..........New York, N. Y.
Buick Motor Co................Flint, Mich.
Cadillac Motor Car Co........Detroit, Mich.
Cartercar Co. ....Pontiac, Mich.
J. I. Case T. M. Co., Inc........Racine, Wis.
Chalmers Motor Co............Detroit, Mich.
Chandler Motor Car Co....Cleveland, Ohio.
Cole Motor Car Co.......Indianapolis, Ind.
Cunningham, Son & Co., Jas.Rochester, N. Y.
F. I. A. T.............Poughkeepsie, N. Y.
H. H. Franklin Mfg. Co.....Syracuse, N. Y.
Garford Co. ....Elyria, Ohio
Haynes Automobile Co........Kokomo, Ind.
Hudson Motor Car Co..........Detroit, Mich.
Hupp Motor Car Co..........Detroit, Mich.
Imperial Automobile Co.......Jackson, Mich.
Inter-State Automobile Co.....Muncie, Ind.
Jackson Automobile Co.......Jackson, Mich.
Thomas B. Jeffery Co.........Kenosha, Wis.
King Motor Car Co............Detroit, Mich.
Kissel Motor Car Co..........Hartford, Wis.
Kline Motor Car Corporation.Richmond, Va.
Krit Motor Car Co............Detroit, Mich.
Locomobile Co. of America.Bridgeport, Conn.
Lozier Motor Co..............Detroit, Mich.
Lyons Atlas Co...........Indianapolis, Ind.
McFarlan Carriage Co.....Connersville, Ind.
Mack Bros. Motor Car Co..New York, N. Y.
Marion Motor Car Co.......Indianapolis, Ind.
Maxwell Motor Co., Inc........Detroit, Mich.
Mercer Automobile Co.........Trenton, N. J.
Mitchell-Lewis Motor Co.......Racine, Wis.
Moline Automobile Co......East Moline, Ill.
Moon Motor Car Co..........St. Louis, Mo.
Motor Car Mfg. Co.........Indianapolis, Ind.
National Motor Vehicle Co.Indianapolis, Ind.
Nordyke & Marmon Co....Indianapolis, Ind.
Oakland Motor Car Co..........Pontiac, Mich.
Ohio Electric Car Co..........Toledo, Ohio
Olds Motor Works...........Lansing, Mich.
Packard Motor Car Co.........Detroit, Mich.
Paige-Detroit Motor Car Co...Detroit, Mich.
Peerless Motor Car Co.......Cleveland, Ohio
Pierce-Arrow Motor Car Co...Buffalo, N. Y.
Premier Motor Mfg. Co....Indianapolis, Ind.
Pullman Motor Car Co.............York, Pa.
Rauch & Lang Carriage Co...Cleveland, Ohio
Regal Motor Car Co..........Detroit, Mich.
Reo Motor Car Co...........Lansing, Mich.
Saxon Motor Co..............Detroit, Mich.
S. G. V. Co...................Reading, Pa.
Speedwell Motor Car Co.......Dayton, Ohio
F. B. Stearns Co............Cleveland, Ohio
Stevens-Duryea Co....Chicopee Falls, Mass.
Studebaker Corp..............Detroit, Mich.
Stutz Motor Car Co......Indianapolis, Ind.
Velie Motor Vehicle Co..........Moline, Ill.
Waverley Co. ....Indianapolis, Ind.
Westcott Motor Car Co......Richmond, Ind.
White Co. ....Cleveland, Ohio
Willys-Overland Co.............Toledo, Ohio
Winton Motor Car Co.......Cleveland, Ohio
Woods Motor Vehicle Co........Chicago, Ill.

The following manufacturers who are not members of the National Automobile Chamber of Commerce will exhibit at both New York and Chicago.

Allen Motor Co.................Fostoria, O.
American Cyclecar Co.....Bridgeport, Conn.
Argo Motor Co................Jackson, Mich.
Cresson-Morris Co..........Philadelphia, Pa.
Crow Motor Car Co............Elkhart, Ind.
Davis Motor Car Co..........Richmond Ind.
Durant-Dort Carriage Co.........Flint, Mich.
Enger Motor Car Co......Sioux Falls, S. D.
Herff-Brooks Corp........Indianapolis, Ind.
Herreshoff Motor Co..........Detroit, Mich.
L. P. C. Motor Co............Racine, Wis.
Lexington-Howard Co....Connorsville, Ind.
McIntyre Co., W. H............Auburn, Ind.
Metz Co....................Waltham, Mass.
Monarch Motor Car Co.........Detroit, Mich.
Milburn Wagon Co...............Toledo, O.
Paterson Co., W. A.............Flint, Mich.
Partin-Palmer Motor Car Co..Detroit, Mich.
Remington Motor Co.........New York City
Sphinx Motor Car Co...............York, Pa.
Scripps-Booth Co............Detroit, Mich.
Twombly Motors Co..........New York City

The following, made up of non-members of the N. A. C. C. are on the list for the New York show only: Pilot Motor Car Co., Richmond, Ind.; Fischer Motor Corp., New York City; Grant Motor Co., Findlay, O.; Crawford Automobile Co., Hagerstown, Md., and Entz Motor Car Corp., New York City.

The following non-members of the N. A. C. C. will exhibit at Chicago only; Bartholomew Co., Peoria, Ill.; Buckeye Mfg. Co., Anderson, Ind.; Empire Automobile Co., Indianapolis, Ind.; Cowles-Macdowell Pneumobile Co., Chicago, Ill.

Accessory Exhibitors of New York and Chicago Shows

American Bronze Co............Berwyn, Pa.
Apple Electric Co..............Dayton, Ohio
Automobile Supply Mfg. Co..Brooklyn, N. Y.

Badger Brass Mfg. Co., The..Kenosha, Wis.
Bearing Co. of America, The..Lancaster, Pa.
Benford Mfg. Co..........Mt. Vernon, N. Y.
Blackledge Mfg. Co., John W...Chicago, Ill.
Bock Bearing Co., The..........Toledo, Ohio
Brown, William H.........Cleveland, Ohio
Brown-Lipe-Chapin Co......Syracuse, N. Y.
Brown-Lipe-Gear Co........Syracuse, N. Y.
Byrne, Kingston & Co.........Kokomo, Ind.

Carr Co., F. S.................Boston, Mass.
Champion Ignition Co............Flint, Mich.
Cowles & Co., C..........New Haven, Conn.
Cramp & Sons Ship & Engine Bldg. Co., The Wm..................Philadelphia, Pa.

Detroit Lubricator Co.........Detroit, Mich.
Dixon Crucible Co., Jos....Jersey City, N. J.
Doehler Die-Casting Co.....Brooklyn, N. Y.
Double Fabric Tire Co..........Auburn, Ind.
Dunlop Wire Wheel Corp..New York, N. Y.
Dykes, John L. G.............Chicago, Ill.
Dyneto Electric Co..........Syracuse, N. Y.

Electric Storage Battery Co., The, Philadelphia, Pa.

Findeisen & Kropf Mfg. Co....Chicago, Ill.

Gabriel Horn Mfg. Co.......Cleveland, Ohio
Garage Equipment Mfg. Co..Milwaukee, Wis.
Garford Mfg. Co., The..........Elyria, Ohio
Gemmer-Detroit Starter Co....Detroit, Mich.
Globe Machine & Stamping Co., The, Cleveland, Ohio
Golde-Patent Mfg. Co......New York, N. Y.
Gray & Davis................Boston, Mass.

Halladay Co., L. P.............Streator, Ill.
Harris Oil Co., A. W......Providence, R. I.
Hartford Suspension Co....Jersey City, N. J.
Hassler, Robert H.........Indianapolis, Ind.
Heinze Electric Co., The......Lowell, Mass.
Hoffecker Co., The............Boston, Mass.

International Acheson Graphite Co., Niagara Falls, N. Y.

J. M. Shock Absorber Co..Philadelphia, Pa.

Kellogg Mfg. Co...........Rochester, N. Y.
Kent Mfg. Works, Atwater..Philadelphia, Pa.
Kokomo Electric Co..........Kokomo, Ind.

Leather Tire Goods Co..Niagara Falls, N. Y.
Lovell-McConnell Mfg. Co....Newark, N. J.

Mosler & Co., A. R........Mt. Vernon, N. Y.
Motsinger Device Mfg. Co..LaFayette, Ind.

National Screw & Tack Co., The, Cleveland, Ohio
National Tube Co...........Pittsburgh, Pa.
N. Y. & N. J. Lubricant Co..New York, N. Y.
North East Electric Co....Rochester, N. Y.

Pantasote Co., The........New York, N. Y.
Pittsburgh Model Engine Co..Pittsburgh, Pa.

Randall-Faichney Co., The....Boston, Mass.
Rose Mfg. Co.............Philadelphia, Pa.
Royal Equipment Co., The.Bridgeport, Conn.

Sager Co., J. H............Rochester, N. Y.
Schrader's Son, Inc., A......Brooklyn, N. Y.
Schwarz Wheel Co., The..Philadelphia, Pa.
Shaler Co., C. A...............Waupun, Wis.
Sparks-Withington Co., The..Jackson, Mich.
Spicer Mfg. Co..............Plainfield, N. J.

Splitdorf Electrical Co.......Newark, N. J.
Standard Thermometer Co....Boston, Mass.
Stewart-Warner Speedometer Corp., Chicago, Ill.

Stromberg Motor Devices Co...Chicago, Ill.

Taylor Instrument Co. (Motometer Co.), New York, N. Y.

United States Light & Heating Co., The, Niagara Falls, N. Y.

Vacuum Oil Co.............New York, N. Y.
Valentine & Co.............New York, N. Y.
Van Sicklen Co., The Aurora, Ill.
Veeder Mfg. Co., The........Hartford, Conn.
Voorhees Rubber Mfg. Co.Jersey City, N. J.

Waltham Watch Co.......Waltham, Mass.
Warner Gear Co...............Muncie, Ind.
Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
Wheeler & Schebler.......Indianapolis, Ind.
Willard Storage Battery Co..Cleveland, Ohio.

Accessory Exhibitors at New York Show Only

Bosch Magneto Co........New York, N. Y.
Budd Mfg. Co., Edward G..Philadelphia, Pa.

Coes Wrench Co..........Worcester, Mass.

English & Mersick Co....New Haven, Conn.

Hartford Machine Screw Co..Hartford, Conn.
Haws, Geo. A.............New York, N. Y.
Herz & Co................New York, N. Y.

Light Mfg. Fdry. Co..........Pottstown, Pa.
Manufacturers Fdry. Co., The., Waterbury, Conn.
Perfection Spring Co........Cleveland, Ohio

Sloan & Chase Mfg. Co. (Motor Compressor Co.) ....Newark, N. J.
Springfield Metal Body Co..Springfield, Mass.
Standard Welding Co., The..Cleveland, Ohio

Ward Leonard Electric Co..Bronxville, N. Y.
White & Bagley Co., The..Worcester, Mass.

Accessory Exhibitors at Chicago Show Only

Buda Co., The..................Harvey, Ill.
Continental Motor Mfg. Co....Detroit, Mich.
Edison Storage Battery Co....Orange, N. J.
Ham Mfg. Co., C. T........Rochester, N. Y.
Imperial Brass Mfg. Co., The....Chicago, Ill.
National Coil Co.............Lansing, Mich.
Remy Electric Co............Anderson, Ind.
Sulzberger & Sons Co...........Chicago, Ill.
Vesta Accumulator Co.........Chicago, Ill.
Warner Mfg. Co...............Toledo, Ohio

Eight Electric Makers Exhibit at Palace

Both Passenger Cars and Trucks Are Displayed—Batteries, Machine Shop, Etc.

NEW YORK CITY, Oct. 10—Over fifty cars are shown by eight exhibiting companies at the Electrical Exposition and Motor Show which opened in Grand Central Palace on Wednesday, October 7, to remain open until October 17. In addition there are a score of other companies exhibiting products of interest and use to electric vehicle owners, while the machine shop and garage shown on the third floor are of interest to gasoline car owners as well.

There are five exhibitors of passenger cars, the Baker Motor Vehicle Co., Cleveland, O., S. R. Bailey & Co., Boston, Mass., Anderson Electric Car Co., Detroit, Mich., Flanders Electric, Pontiac, Mich., and Rauch & Lang Carriage Co., Cleveland, O. There are three exhibitors of trucks, Commercial Truck Co. of America, Philadelphia, Pa., General Vehicle Co., Long Island City, and Ward Motor Vehicle Co., New York City. Some of the exhibits are described herewith:

The Baker exhibit consists of a single car—a double-drive brougham model BBD upholstered in dark green cloth. The lever control system is fitted with an interlocking device preventing the use of more than one set at a time. The control lever is set just above the steering lever and is considerably shorter. The controller is of the continuous torque drum type and gives six speeds forward and three reverse. An automatic circuit cuts off the current when the emergency brake is applied and the current cannot be turned on again until the brake is released. The body work is up to date, the panels being of aluminum, window sashless with mechanical lifters and equipment being complete. The car sells for $3,000 with bevel gear drive and $3,250 with worm drive.

The Rauch & Lang company shows two cars, both broughams, one a double drive model costing $3,200 and the the other a single drive at $2,950. The former is finished in gray and the latter in black. Both have the characteristic R. & L. worm drive system in which the motor drives through a short propeller shaft with two universal joints direct to the worm. The worm is carried on ball bearings above the gear. The springs are long and flexible, sashless windows, deep and comfortable upholstery, complete lighting and full equipment being provided.

The Anderson company has the largest exhibit of pleasure cars, showing two Detroit Electric broughams and one cabriolet. These models were fully described in THE AUTOMOBILE for October 8 and further comment is unnecessary than to state that they are up to date in every particular and fitted with the most complete equipment. All but one of the six body types for 1915 are mounted on 100-inch wheelbase underneath worm drive chassis, while the other is fitted to a 94-inch bevel drive chassis. Among the improvements on the new cars are: The new wiring method, facilitating body removal, increase in battery capacity, better protection for mechanism, and the drip molding over the doors for production against the rain. Prices on Detroit electrics range from $2,660 for the 94-inch wheelbase car with lead battery to $3,880 for the five-passenger with Edison battery.

The General Vehicle Co. shows a 2-ton chain drive chassis on the third floor which is painted in a variety of colors, each color distinguishing a separate system; for instance, the brake system is all one color, the control system another, the drive system another, and so on. There is a large chart explaining the significance of the various hues. On the track there is a 1,000-pound chain drive car with a standard department store type of body. The exhibit on the main floor consists of two cars, a 1,000-pound worm driven truck with panel body and doors, as in pleasure cars, at the driver's space, and a 1-ton chain drive model with standard panel body.

The Commercial Truck Co. shows a 1,000-pound truck with two-motor drive direct to the wheel, there being no axle shafts or other intermediate members except for the reduction gears, which are built into the casing between the motor and the wheel. Thus the differential is eliminated and a strong type of double axle used. The company builds trucks up to 7 tons capacity and in the models from 3 1-2 tons up, four wheel drive is employed, there being steering pivots for all four wheels, permitting four wheel steering also. The motors swing with the wheels. In the small type worm drive also is employed. Upstairs on the track, on the third floor, there is a 1-2-ton truck running and also a two-motor taxicab.

An extensive exhibit is made by the Ward company comprising four trucks and a chassis, ranging from the new little delivery car with steel panel body, the price of which is $875, to a big 5-ton truck. The little car is a new model having a Westinghouse motor driving through a jointed propeller shaft to the Timken rear axle. The carrying capacity is 750 pounds. Equipment is complete. The regular battery equipment of the Ward trucks is Philadelphia, although any battery the purchaser prefers will be installed. Other Ward exhibits include the 1,000-pound trucks used for delivery and heavier types in which final drive is through a jackshaft and chains and to the jackshaft from the motor through a silent chain.

The garage and machine shop exhibit on the third floor includes a variety of machine tools ranging from a heavy motor driven lathe to a light drill press. There are milling machines, shapers, electrical controls and switchboards, forges, vises, etc. The Andrew Greis Co., New York City, shows a corrugated steel garage beside the track on which demonstrations and tests are being given.

Philadelphia, Exide, Edison and Gould batteries are shown complete and in detail and although there are no radical changes it is noticeable that thin plates are much favored for lead batteries. By designing these plates so that the sediment spaces are sufficiently large to hold all the deposit until the plates are worn out, the necessity for washing is eliminated.

The Automobile Club of America has an exhibit where information on roads, sign boards of various types and general tourists' information is available. The Electric Vehicle Assn. of America has an exhibit of charts of electric truck operation costs, amount of money invested by express and transfer companies, public utilities companies, department stores, Federal Departments, etc. The reduction in charging rates brought about during the last few years is also charted.

Hupp to Continue Model 32

DETROIT, MICH., Oct. 13—The Hupp Motor Car Co., has decided, owing to the general demand of its dealers, to continue to manufacture in 1915 the Model 32, in addition to the new model K announced some time ago.

Next season's price for the model 32 roadster and touring car is $950 f.o.b. Detroit instead of $1,050 this year, and the price in Canada is $1,230 f.o.b. Windsor. At these figures electric starter and lighting system are not included, but with such equipment the price will be $1,050, as compared with $1,200 in 1914.

The two models, roadster and touring cars, will remain the same in general construction as they have been this year, except in refinements of details.

The 32 has a four-cylinder block motor, 3 1-4 by 5 1-2, multiple-disk clutch, cooling by thermo-syphon, positive-feed lubrication, high-tension ignition and selective three-speed gearset. The rear axle is a floating type. The wheelbase is 106 inches. Tires either 32 by 3 1-2 or 33 by 4, the latter with cars having the electric starter and lighting system.

24 Makes of Small Cars at Boston

BOSTON, MASS., Oct. 12—Twenty-four makers and dealers of small cars are holding an exhibition or show in Horticultural Hall this week, opening today and continuing until Saturday. Thirty-one cars are on exhibition, representing twenty-four different makes. There is a great difference between the machines exhibited and the cyclecars seen in this city last spring. Instead of the twin air-cooled motor there are many four-cylinder, water-cooled types, and the belt system of transmission has largely given way to selective sets with shaft drive. The narrow tread with tandem seating is not present in such quantities as it was 10 months ago, there being a tendency to approach nearer to the standard 56-inch tread, although there are several treads under 40 inches, in which staggered seating is used.

One purpose of the present show seems to be a concerted movement to impress on New Englanders the change that has been wrought during the last 10 months, demonstrating the passing of the cyclecar and the stepping up into the regular automobile field. Today it is a standard design of motor, only smaller; a standard gearset, only smaller; a standard transmission system, only smaller;; a standard body design, only smaller; in fact, there is not any division in the automobile field as many would like to make out, rather the cyclecar movement has almost spent itself, and those who have come through the last year of development are today building smaller-sized motor cars, that have all of the components, or most of them, of the moderate car.

Among the different makes exhibiting are Coey, Carnation, Dayton, Dudley, Imp, Kearns, Merz, Mohawk, Morgan, Mercury, Peter Pan, Princess, Remington, Sigma, Scripps-Booth, Saginaw, Salvador, Trumbull, Tiger, Twombly, Vim, Vixen and Zip.

There are twenty-one different makes exhibiting four-cylinder motors, practically all of which are water-cooled types, a fact which proves the passing of the twin two-cylinder, air-cooled motor which was so much in the public eye when the cyclecar movement was started. The majority of the cars exhibited are for two passengers in which they are seated side by side rather than tandem. Some of the concerns which manufactured some of the cars on exhibition are not manufacturing at the present time.

Hess-Bright Wins Bearing Suit Appeal

Conrad Patent on Continuous Race Held Valid and Lower Court Reversed

PHILADELPHIA, PA., Oct. 7—Reversing the decision of lower court, the Philadelphia Circuit Court of Appeals today handed down a decision in favor of the Hess-Bright Mfg. Co., in its suit against the J. S. Bretz Co. alleging infringement of the Conrad patent Numbers 822,723 and 838,303 covering the continuous and uninterrupted race type of construction in ball bearings.

The suit was brought last year by the Hess-Bright Mfg. Co. of Philadelphia, Pa., and the Deutsche Waffen und Munitions Fabriken of Germany, against Hedwig Fichtel and Ernst Sachs of Germany, doing business as Fichtel & Sachs, and their exclusive American representative, the J. S. Bretz Co., of New York.

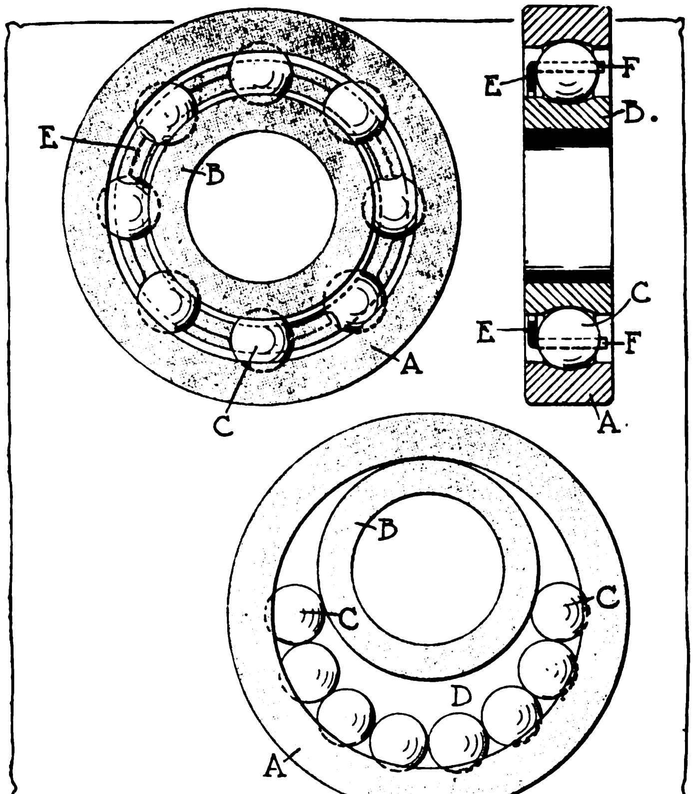
Judge McPherson in the U. S. District Court of Philadelphia handed down a decision in favor of the defendants last December, and shortly afterward the Hess-Bright interests appealed the case to the Circuit Court of Appeals, which has just decided in their favor.

In a nutshell the decision states that the F. & S. bearing infringes because it is a ball bearing with a continuous grooved race surface while in actual operation. Although the F. & S. bearing has an opening in the groove through which the balls are inserted, the groove is not fully interrupted and therefore is continuous after the bearing has been assembled.

The case was argued before Circuit Judges Buffington and Hunt and District Judge Witmer. In the decision Judge Buffington brought out the following points:

"It will be noted that Conrad patents for finished ball bearings adapted for use and not for the method of assembling. Thus in his patent he says: 'I do not claim in the present application to describe method of assembling the parts of my improved ball bearing, this method being claimed in a divisional application filed May 18, 1906.' And, as showing that his patent was for a finished ball bearing, adapted for use, he says: 'The principal advantage of the new bearing lies in the continuity of the size of the groove, which insures the regular running of the balls, and consequently great durability of the bearing.'

"The practical ball bearing art as practiced prior to Conrad's patent was well described by Judge Holland in 177 Fed. Rep. 144 in these words: 'Many patents have been issued for ball bearing devices, which have not been entirely satisfactory for the reason that the tracks or ways were interrupted and the ball consequently could not travel freely therein. It was old to have inner and outer rings with opposing grooves, but the sides of these grooves were interrupted in one way or another to permit the introduction of the balls. In some cases, filling openings were provided and in some instances these were filled up or plugged after the balls had been introduced in order to prevent the escape, but these prior devices were defective in that the raceways would crumble or were at the interrupted parts of the raceway, and then the injured balls would cause undue wear to the remaining portions of the raceway, and thus the bearing suffered a rapid depreciation, and often entire failure in a comparatively short time, and where the filling openings were plugged to prevent the escape of the balls the



The Conrad ball bearing patent embodies two concentric rings, A and B, having between them a number of balls, C. Each ring has a groove, the sides of which overhang the balls to a slight extent. The edges of the rings are spaced so far apart that they may be displaced, leaving a crescent-shaped space, D, for the insertion of the balls. The rings can then be restored to the concentric position and the spaces, F, which are held together by the ring, E, shown in section, keep them in their relative positions

plugs could not be given precisely the same temper as the rings forming the remaining portion of the raceway, and unequal wear would ensue which resulted in injury to the balls and raceway, and an undue shortening of the life of the bearings. These bearings could safely be subjected only to light loads, and were entirely unsatisfactory and not fitted for use in heavily built rapid moving vehicles."

"Conrad simply brought into the art a metallically unbroken groove pathway for the balls. This pathway he kept unbroken by introducing the balls by eccentric displacement of the rings; the retention of the balls and the concentricity of the rings he effected by ball spreaders. Conrad's novelty and contribution to the art consisted in disclosing the actual use of a continuous or unbroken groove as a pathway for a ball bearing.

"The specification as originally made, together with all the claims, were not satisfactory to the office—a fact possibly due to the non-familiarity of the foreign applicant with American patent requirements—and in the subsequent proceedings each and every one of the original claims were rejected. The entire original specification was then withdrawn and another substituted. These facts are all important for the contention of the defendant in effect is, that the claims granted should be given the effect the claims originally made would have had. That the device itself for which Conrad received his final claims was the same one for which he sought his original claims there is no question. But while Conrad had in view the broad, general character of the ball bearings he there disclosed and illustrated, we think, his specification as originally drawn did not specifically and with exactness define wherein the precise inventive feature of his device lay nor did he properly confine his claims to such inventive feature. As we have seen, the gist of the ball bearing disclosed by Conrad was the unbroken, continuous, unrecessed and integral grooved pathway. When, however, he came to make all three of his original claims they were each and all not for such grooves, but for rings 'unrecessed and unbroken.' While of course, such an 'unrecessed and unbroken' ring undoubtedly physically had on its face Conrad's 'unrecessed and unbroken' groove, yet the unbroken face of the ring was a mere mechanical strengthening incident for no matter how much the ring face, as a face unbroken and unrecessed, the invention did not lie in the integrity of the ring face but in the continuity of the sides of the groove. Such being the case, it is clear that the claim originally made for rings 'unrecessed and unbroken' needlessly embodied in the claim the narrowing limitation of necessitating the ring surface to be unbroken when the real invention lay in requiring the groove side to be unbroken and unrecessed. And anticipating what will later be apparent we may here say that if Conrad's claims had thus remained for 'unrecessed and unbroken' rings the defendant would have avoided infringement of this narrow claim by merely slotting its rings though in doing so it had cut into and broken the continuity of the sides of the groove. Presumably attention must have been called to this fact by the office, since in the new specification and the claims which met the office approval, this oversight was remedied and in the new specifications it was shown that 'the principal advantage of the new bearing lies in the continuity of the side of the groove' and new claims were made, not for rings 'unbroken and unrecessed' as before, but for 'opposing grooves on their adjacent faces, the sides of said grooves being uninterrupted throughout their circumference,' 'each ring having a groove both sides of which overhang said balls and are continuous and practically integral throughout their circumference.'

"We find nothing in the way of prior patenting or use that suffices to shear Conrad's device of patentable novelty, for without entering into a discussion of the prior art, we may say that while ball bearings were known and used, there was prior to Conrad no use of ball bearings in the high speeds and heavy loads which his device has made possible. . . . We therefore hold the claims of his patent here involved are valid.

"The question of infringement practically and mechanically turns on the effect and sufficiency as a ball confiner of a steel dam or barrier so slight in height that its gradual rise from the central line of the balls' grooved pathway ceases when 44-10,000 of an inch is reached. The Court below said: 'How such a minute fraction as 44-10,000 of an inch would 'overhang' is not perceptible.' At bar, counsel for complainant stated, that if this defendant cut his channel entrance deeper by 44-10,000 of an inch all questions of infringement would be abandoned. That the curve does 'overhang' the ball is, we think, self evident.

"The methods of introducing the balls are practically the same in the case of both complainant and defendant, the slot-inserted additional balls of the defendant's device being the mechanical equivalent of Conrad's spreaders.

"The decree dismissing the bill must therefore be reversed and the case remanded with directions to the court below to enter a decree holding the claims in issue valid and infringed and directing an accounting."

Cuts Gasoline Price—Raises Storage

NEW YORK CITY, Oct. 13—The movement on the part of New York's West Side garagemen to raise storage $5 a month and place gasoline on a 5-cent profit basis has not met with the success anticipated. About thirty garagemen were affected and it was expected that they would make their rates $35 and $40 a month in non-fireproof garages and $40 and $45 in fireproof garages.

One of the leaders in the movement was Morris Segall, of the Apthorp Garage, 214 West Eightieth street, and when, as he states, he found that his competitors were cutting storage rates and taking in cars at the old schedule he decided to take action against them. Accordingly he has reduced gasoline to 16 cents—a 3-cent profit—and is selling it at that figure. His storage remains at the new schedule.

Under the old rates of about 22 cents for gasoline and the old prices for storage, garagemen stated that the sole profit of the business came from gasoline, oil and supplies, and the storage increase was sought as a real business move.

Disappearing Safety Signs for Detroit

DETROIT, MICH., Oct. 12—The Police Department has presented a project for the establishment of disappearing safety zone posts, that would be in the shape of iron standards carrying a marker upon which the words "Safety Zone" would be written. The posts are to be embedded in the streets fitting in an iron casing in which they would be locked up at night. They could be raised and lowered by the traffic officers and will have chains attached to them to mark off the street car stopping zones. The advantage of such posts will be to leave the streets entirely free for parades or any special events and would also do away with the suggested platforms. If desired a light could be provided for the posts.

Illinois Garage Owners' Association Formed

CHICAGO, ILL., Oct. 13—The National Garage Owners' Assn. has been formed in Chicago and has opened offices at 2431-41 Cottage Grove avenue. F. E. Christian is president and G. E. Pfleger is secretary of the garage men; M. I. Iles is president and C. B. O'Hare is secretary of the supply men.

Maxwell Earns 12 Per Cent. on First Preferred

Net Earnings for Fiscal Year Total $1,430,444.52—Quantity Production Economical

NEW YORK CITY, Oct. 12—The annual report of the Maxwell Motor Co., Detroit, Mich., whose fiscal year ended July 31, 1914, shows net earnings of $1,430,444.52, or 12.26 per cent. on the first preferred, after deducting costs of manufacturing and expenses of advertising, selling, administration and taxes. Other income, including cash discounts on goods purchased and sundry miscellaneous revenue, amounted to $339,979.02, while the total income amounted to $1,770,423.54. Deductions, that is, depreciation on buildings, machinery and tools, over and above repairs and replacements, amounted to $264,956.45, bringing ten net income, or surplus, for the year to $1,505,467.09.

The general balance sheet shows: Assets—real estate, machinery and equipment, $4,462,222.42; investments, $694,656.15; good-will, models, patents, trade marks and trade names, $26,500,000; current working assets, inventories, $4,588,972.70; accounts receivable, $428,495.55; notes receivable, $212,455.36; prepayments, $50,898.46; cash, $1,785,992.68,992.68, total assets, $38,723,693.32.

Liabilities: First preferred stock, $13,000,000; less in treasury, $720,667.99; second preferred stock, $11,000,000; less in treasury, $872,532.01; common stock, $13,000,000; less in treasury, $221,942.42; real estate, mortgages, $30,160.60; current liabilities, $951,490; reserve for depreciation of capital assets, $280,132.68; reserve for contingencies, $100,000; surplus, $1,505,467; total liabilities, $38,723,693.32.

In his report to stockholders President Walter E. Flanders says: "Early in the first fiscal year the management became convinced of the wisdom of concentrating its energy on a large volume of production of moderate priced Maxwell cars. Accordingly preparations have been under way during the past 10 months to bring the factories in Dayton, Newcastle and Detroit up to a large production which is particularly adapted to a quantity production of one model car has been installed at all of these plants. The Maxwell Motor Co., Inc., is especially fortunate in that it produces nearly the complete automobile from raw materials in its own factories, which effects a large saving in costs over assembled cars.

"The net working assets of approximately $6,000,000, of which over $1,750,000 is cash, place your company in a strong position. Although the net earnings of the company amount to more than $1,500,000 as against annual dividend requirements on the first preferred stock of $895,553, the management has deemed it advisable to conserve the liquid assets of the company for the development and extension of its business. Therefore, no dividends have been declared."

Market Reports for the Week

A few prices declined in this week's market reports. These were $0.00 1-4 for antimony, $0.50 per ton for Bessemer steel, $0.20 per barrel for cottonseed oil, $0.04 for linseed oil and $0.87 per 100 pounds for tin. Electrolytic copper rose to $0.11 7-20 while the Lake copper rose to $0.11 1-2 per pound. Rubber, fine Up-River Para remained constant throughout the week at $0.64.

Franklin's Sept. Shipment Increase 743%

SYRACUSE, N. Y., Oct. 13—The Franklin Automobile Co., this city, is showing a large increase in business. Shipments during August and September show an increase of 254 per cent. over the same 2 months of last year. For September the shipments were 743 per cent. over the same period of last year. For the 3 months of July, August and September the shipments were 124 per cent. over the same period last year. For the 12 months ending September 30, sales were 88 per cent. over the previous 12 months.

Efficiency Survey in Financial Difficulties

CHICAGO, ILL., Oct. 14—*Special Telegram*—An involuntary petition in bankruptcy was filed in the United States District Court, in Chicago, Monday, October 12, against the American Efficiency Survey of Motor Car Units, a corporation formed for the purpose of making tests of various motor car parts and accessories. The liabilities of the concern are said to be in excess of $60,000. The Central Trust Co., Chicago, has been made receiver;; the assets, according to the attorney for the petitioning creditors, consist of office furniture in the company's twelve-office suite on Michigan Boulevard.

The American Efficiency Survey of Motor Car Units came into prominence 6 months ago when its president, Harry Newman, announced that day and night tests were being conducted at the testing laboratories of Purdue University with a view to advising motor car manufacturers as to the merits and demerits of their products or parts. No reports have been made public up to this time, but it was stated by the president some weeks ago that data for publication would be ready in a short while.

Electric System for Saxon, $70 Extra

DETROIT, MICH., Oct. 14—*Special Telegram*—The Saxon Motor Co. is now furnishing its cars with an electric starting and lighting system, if so desired, at an addition of $70, the price of the car thus being $465.

26,811 Cars Licensed in Connecticut

HARTFORD, CONN., Oct. 12—The secretary of state's business for the year which has just come to a close amounted to $406,623.34, an increase of $85,826.82. Licenses issued for passenger and commercial cars were the greatest source of revenue.

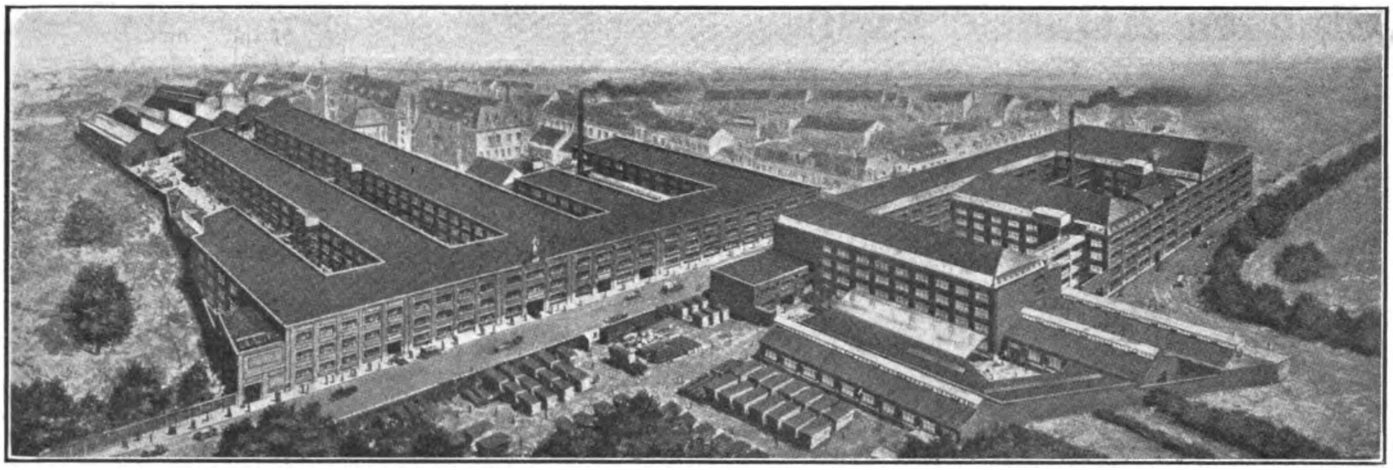
In 1913, 22,440 licenses were issued, for which the sum of $226,650.10 was received.

For the fiscal year of 1914 the number of licenses was 26,811 and the revenue was $291,371.36. There were 823 livery cars licensed in 1913 and 1,289 in 1914, the revenue increasing from $6,529.30 to $10,302.10.

There was a big drop in the number of dealers' licenses. In 1913, 372 dealers were registered, in 1914, 171, a drop of approximately 54 per cent., which may be accounted for by the fact that the dealers' rate was increased this past year which had a tendency to eliminate many of the so-called dealers who never registered more than one car. This past year the dealers' rate was $50, against $20 a year back. However, the revenue increased from $6,955.82 in 1913 to $7,224.97 in 1914, or approximately an increase of 3 per cent. There were 36,372 operators' licenses issued in 1914, against 30,199 in 1913, a jump of 20 per cent., and the fees jumped from $60,398 in 1913 to $72,744.

163,604 Cars Registered in New York

NEW YORK CITY, Oct. 13—Mitchell May, Secretary of State, announced recently that since February 1 last, 163,604 automobiles have been registered in this state, 69,197 representing new machines registered and driven for the first time by resident owners, 28,888 being resident owners of New York City. After August 1, when the law allows one-half rate for all original registrations, there have been 8,578 new cars, 3,425 belonging in New York City. The total number of cars registered for the entire 12 months of last year amounted to 134,405, of which 61,094 were originals.



Bird's-eye view of the Minerva Motor Works at Antwerp, destroyed in the recent siege of the city. One of the buildings was used by the Belgians for making firearms and ammunition

90 Per Cent. of Passenger Cars in Red Cross Work

NEW YORK CITY, Oct. 12—J. R. Clarke, recently with the Packard company in Paris, France, has just returned to this country after serving nearly 1 month as driver of a Packard car in the service of the Signal Department of the Allied Army. During 18 days of service of this capacity he had an opportunity of observing many of the conditions that motor trucks and passenger cars are confronted with in the war work. Fully 90 per cent. of all the passenger cars are being used in Red Cross work. These cars are suffering largely from lack of drivers. Frequently taxicab drivers are placed on high-powered cars with which they are not familiar and accidents are frequent. Many of these taxicab drivers are not familiar with necessary care a car should receive, and consequently there are many cars destroyed through sheer carelessness.

There is much danger connected with driving cars in any service, largely because the lights are put out in the city streets and at points along country roads for safety purposes. They are not allowed to use headlights and as there is practically as much driving done at night as in the daytime there are many cars destroyed. Many Ford cars are at present being used in the ambulance service. When war broke out a number were requisitioned by the government and at that time the company started to equip a number of chassis with ambulance bodies which are proving satisfactory.

Mr. Clarke had an opportunity of observing the work of the motor truck convoys in the transportation of ammunition and supplies. At times 150 to 300 trucks are run in convoys, successive trucks being about 50 yards apart. They travel generally at 15 miles per hour and keep on the regular roads, there being such a network of these that it is not necessary to do any cross-field work.

At present the English army is losing approximately 100 trucks a week and the French army an equal number due to the average destruction which occurs. For example, a truck halts at the roadside to make some repair and if the driver leaves it there is danger of the drivers of other vehicles stealing magnetos, carbureters, or other spares which they require. Because of this many trucks are eventually destroyed for minor troubles.

The broadest use of motor trucks for the different armies is from what is known as Pailhead, which means the end of the railroad system in use, to within a short distance of the firing line, in fact, provision wagons are operating right up to the trenches in some places and Red Cross vehicles are also working right to the firing line.

The Goodrich tire factory in Paris is being operated by the government which is manufacturing solid rubber tires for trucks. Practically all of the other factories in France are being operated by the army, but in many the output is very restricted because of lack of material.

At present ten Packard cars are being used in service of the American ambulance and Red Cross work.

Minerva Works Near Antwerp Destroyed

AMSTERDAM, Oct. 12—Dispatch to London *Daily Chronicle*—The following details of the occupation of Antwerp by the Germans have been given by Dutchmen who have been there since Friday:

Most of the damage done by shells is in the southern part of the town in the suburbs of Berchem and Zurenberg. Among the buildings destroyed were the St. Joseph's Church, Hippodrome and the Minerva Motor Works.

The Minerva works consisted of two large four-story buildings, on opposite sides of the street. The newer of these two buildings was largely filled with American-made machinery, while the old building was used for repair work, pattern-making, drafting, etc. Early in the war a great deal of machinery was brought down from the F. N. works in Liege. This machinery was used in the manufacture of fire arms and ammunition, automobiles, motorcycles, etc. It was installed in the old Minerva works, and most of the Belgian shells were made there. Owing to this fact it is probable that the Belgians blew up the buildings rather than let them fall into the hands of the Germans. The capacity of the Minerva works was fifteen automobiles a day. The buildings were situated just across the street from the fortifications, the ends of both structures being toward the forts.

The S.A.V.A. works, which manufacture the S.A.V.A. car, are situated nearer Antwerp, being nearly a mile from the Minerva works, so they may have escaped destruction.

The F. N. works at Liege, as well as the Derihon factory, are intact and some departments are working.

$200,000 May Be Devoted to Armored Trucks

WASHINGTON, D. C., Oct. 10—According to information gleaned from army officers and members of Congress, the next military appropriation bill will carry a paragraph setting aside $200,000 for the purchase of a certain number of armored motor cars for the use of American troops. Sentiment for such an appropriation has developed in Congress with surprising rapidity since the European dispatches began to tell of the extraordinary efficiency of armored cars in the present conflict abroad.

It is pointed out that today the United States is the only great world power which has no armored cars in its military equipment. Europeans have recognized their theoretic value for the past two or three years and the conclusions which they have reached in time of peace have been more than verified by the events of the war.

Representative Anthony, of Kansas, as previously reported in these columns, has announced he will shortly introduce a bill for the purchase of armored cars for the war department. He is convinced that there is more than enough sentiment in Congress to pass his bill through both houses. His opinion of the necessity of acquiring this equipment for the troops is backed up by the expert opinion of many army officers.

An army officer who does not wish his name to be used at this time, in discussing the subject said: "It is the opinion of many authorities on this subject that it is high time for this government to begin developing the possibilities of the armored car. It seems only reasonable that as the motor car is developed more and more, all food and other supplies will be transported by means of that vehicle. And, by the same token, it seems safe to assume that an attempt will be made to have all these cars armored as thoroughly as possible. Therefore, it does seem that the United States cannot afford to lag behind any longer in developing what is bound to become one of the most important and essential features in all military equipment."

Chicago Athletic Assn. Wins Interclub Run

Captures Ray Cup—Automobile Club Wins Cup For Most Perfect Scores

CHICAGO, ILL., Oct. 17—The Chicago Athletic Assn won the interclub team match between it and the Chicago Automobile Club with a score of 177 demerits as against 244 for the losers. There were sixty cars in the contest, thirty-seven representing the C. A. C. colors and twenty-three for the other club. In addition there were eight official cars.

The winning club took the Allen S. Ray cup while the automobile club took the Carelton White cup, given for the greatest number of perfect scores, the C. A. C. having twenty-nine as against sixteen for the C. A. A.

The run was a 1-day affair, going to George Ade's farm at Brook, Ind., for the noon stop, a distance of 95 miles. The afternoon run was 82 miles, finishing at the South Shore Country club, where the losing team paid for the dinners.

A feature of the match was the competition of Ralph de Palma and Joe Dawson. Both made perfect scores, de Palma driving a Chandler and Dawson a Marmon. This was Dawson's first appearance since his accident at Indianapolis on May 30.

Three failed to finish and in each case there was a penalty of 250 points given. Forrester in a Packard was put out when another contesting car punched a hole in his gasoline tank. Hosmer in a Hudson was disabled, while Rankin in a Cole never checked in. Most of the other penalties were of a minor character.

Mitchell Perfect in St. Louis Run

ST. LOUIS, MO., Oct. 10—A Mitchell was the only car to make a perfect score and get 1,000 points in the 126-mile owners' reliability run today conducted by the Automobile Club of St. Louis. It contested in Class B for roadsters.

In the Class A division for touring cars the first five cars to finish were Franklins with respective scores of 996, 995, 994, and two with 993 points each.

In the roadster division a Mercer was second to the perfect-score Mitchell with a score of 996 points and a Henderson was third with 995 points.

Two women drove in the contest, one in a Stutz finishing fifth in the runabout division and the other finishing third in a Franklin.

The route was over the hilly roads outside of the city and seven checking stations were used. The roads were poor owing to recent rains.

A penalty of 1 point was given for being off schedule, while other penalties were given for the stopping of the motor, rendering of assistance to contestants, taking on supplies at any other than the one checking station at Pond, for hitting or being hit by another car and for being arrested.

London Dealer Secures American Agencies

NEW YORK CITY, Oct. 10—Frank Morriss, a motor car and accessory dealer from London, England, and who has recently been in this country for upwards of 3 weeks, has secured numerous agencies for cars and parts which shows the activity towards American goods that is being manifested abroad at the present time. Among the arrangements made are those covering Salisbury axles, Zephyr carbureter, Imperial car, Scripps-Booth small car, Signal truck and farmer motor.

Six Entries for Corona Road Race

CORONA, CAL., Oct. 7—Six entries have been received for the Corona road race to be held here Thanksgiving Day. Three Mercers have been entered by the Pacific Coast Mercer agency.

Walter M. Brown, Los Angeles sportsman and manager of the Stutz interests throughout Southern California, has entered three Stutz cars. Earl Cooper, winner of the Corona classic last year, has been named as the driver of one of the cars. Gil Anderson is the second member of the Stutz team and Barney Oldfield is slated as the driver of the third Stutz.

Frank Young has announced that he will enter the Ono racer which was wrecked at Tacoma, July 4. The Ono is the Fiat which won the Santa Monica road race two years ago. The Fiat engine has been displaced by a Pope-Portola motor and the car has been rebuilt completely.

Sigma Stars at Small Car Races

BOSTON, MASS., Oct. 10—A program of small car races was held at Combination Park, Medford, this afternoon before a good crowd. There were ten machines entered. The opening event was 5 miles for Class A cars and it was won by the Dudley Bug. The Sigma won three events, the 5-mile class B, 2-mile match race between this car and the Tiger and Zip and a special match race with the Tiger at 2 miles. The big event was the 50 kilometer, free-for-all. The race was won by the Tiger, with the Coey Bear second and the Imp third.

Fuel Tax Protests Flood Congress

WASHINGTON, D. C., Oct. 13—*Special Telegram*—Despite the fact that the Senate Democratic caucus decided to eliminate the tax on automobiles and gasoline, Congress continues to be flooded with protests against the proposed tax. If the house has any idea of reviving the tax the thousands upon thousands of protests surely will tend to convince the representatives of the people that such a tax would be a death blow to one of the greatest industries in the country.

Senator Simmons, Chairman of the Senate Finance Committee in a speech, said that a war emergency tax would prove unpopular.

Senator Borah in a sensational speech yesterday predicted that another revenue measure would have to be passed in a short time imposing additional taxes, and if this were so automobile manufacturers are likely to suffer.

Yesterday, Senator Simmons tried to get an agreement by unanimous consent for vote on the war revenue bill October 22, but Senator Overman objected and disclosed for the first time that senators from the cotton growing states were preparing to offer as an amendment to the war bill, legislation to help out cotton planters in the South.

To Reorganize Piggins Truck Co.

RACINE, WIS., Oct. 13—The Piggins Bros. Motor Truck Co., Racine, Wis., which went into bankruptcy about a year ago, is being reorganized by the Piggins brothers and expects to resume operations about November 1 in the former plant on West Sixth street. The entire equipment was sold at bankrupt sale to the Badger-Packard Machinery Co., Milwaukee, and most of it has now been repurchased and is being installed in the plant. The Racine company has secured ample financial backing.

Voiturette May Auction Off Cars

DETROIT, MICH., Oct. 9—At the meeting of the creditors of the American Voiturette Co., held at the Detroit Trust Co., receiver, it was decided to continue and build quite a large number of Car-Nation cars and a few Keetons for which all the needed parts and material to assemble them is on hand. Together with the finished Car-Nations on hand there will be 375 such cars which will be offered for sale at a uniform price of $250, while the Keeton cars will be offered at $1,000. If the Detroit Trust Co. does not receive a satisfactory offer within the next few days, it is likely that an auction sale will be arranged to dispose of the cars.

According to the statement which was issued by the Detroit Trust Co., concerning the affairs of the company, the total assets are $477,294.76, while the liabilities are $508,889.77.

Urges Adoption of Metric System

LONDON, ENGLAND, Oct. 3—The metric system of weights and measures prevails in the great majority of neutral countries with which hitherto Germany has carried on a very large trade, and if the efforts to capture that trade are to be successful British manufacturers and shippers must adapt their methods to those of their customers. This is made quite clear by the recent Board of Trade reports which confirm what this association has been preaching for years past.

The Decimal Assn. will do its best to help manufacturers and merchants who need advice on this subject, and if sufficient support be forthcoming for the campaign a series of lectures under the auspices of Chambers of Commerce will be held during the winter. Legislation is obviously out of the question for the time being, but every effort will be made to awaken public opinion to the necessity for the change, and to show that in many centers it is indeed impatiently demanded. Not only do our obsolete and cumbersome weights and measures hamper our external and internal trade, but the time wasted in teaching them in schools might well be put to very much better use.—G. E. M. JOHNSON, Secretary of the Decimal Assn.—*The Autocar.*

Governor Will Ride in New York Pageant

NEW YORK CITY, Oct. 13—When a Committee from the New York Commercial Tercentenary Commission, including Colonel Louis Annin Ames, Commissioner William J. Lee, and E. A. Norman, visited Governor Glynn at Albany last Tuesday and extended the Commission's formal invitation for him to participate in the Tercentenary Automobile Pageant on the night of Wednesday, October 28, the Governor not only accepted and agreed to review the Pageant from the Court of Honor, but to ride in the parade over the full line of march as well. He also will be accompanied by his military staff. Mayor Mitchel and numerous other high officials have been invited to ride in and review the pageant, including Secretary of Commerce Redfield, Secretary of State Mitchell May, General Nelson A. Miles, Mayor Preston of Baltimore, and the Mayors of numerous other cities.

Indiana S. A. E. Studies Cord Tire Making

INDIANAPOLIS, IND., Oct. 14—The October meeting of the Indiana Section of the Society of Automobile Engineers was held in the Hoosier Motor Club Rooms, Claypool Hotel, last evening. The subject of the evening was: Steps in the Process of Manufacture of the Latest Types of Automobile Tires with Special Reference to the Cord Tire and Its Advantages, by Otto F. Wagenhorst, of the B. F. Goodrich Co., Akron, O.

The Engineering Digest—Carey's Oil Transmission

(*Continued from page* 722)

pens to be under pressure, this automatic throw-over valve consisting of a ball working between two conical faces; it also connects the balancing areas of both the pump and the motor valves to the pressure side of the apparatus. Some of these details are indicated in the section to the right of the illustration.

With regard to the practical advantages of the Carey construction, it is noted that the whole machine is contained in a single body casting of even bore throughout and is easily accessible, as all the parts can be withdrawn from either end by unscrewing the end covers. The machine work is simple and internal packings are not required, the only packings being leather washers around the ends of the rotating shafts, and these have little pressure upon them, being separated from the working oil by a series of minute passages, in the shape of play in the various bearings, acting as reducing valves.

Further developments of this transmission, in the direction of adapting it for use in automobile chassis, are expected.—From *The Engineer*, August 14.

Utilizing the Camshaft for Power in Renault 8-Cylinder Motor

With the advent in the American market of the 8-cylinder V-type motor some of the features which have been associated with this style of motors in Europe claim attention and serve to throw light on possible new developments. The reduction in the size of cylinders which would naturally follow, for given power requirements, where an 8-cylinder power unit were adopted to take the place of a 4-cylinder one, suggests at the same time cooling by air draft instead of by water. While the De Dion-Bouton 8-cylinder motor is water-cooled, the Renault aviation motor which is arranged on the same plan, though with either 8 or 12 cylinders, is air-cooled. It also is remarkable for being arranged to drive a propeller screw through its camshaft, which is located in the crotch of the V, and the camshaft gears are consequently made substantial enough for transmitting the power. The main object of this arrangement is to reduce the speed of the propeller to 900 revolutions per minute with a motor running at 1,800 revolutions at its best—the propulsion efficiency being thereby increased 15 per cent., it is said—but when it is contemplated to use a similar motor for automobile purposes, especially for trucks, and to get the advantage in compactness to be obtained by using a motor of small dimensions and relatively high speed, the value of reducing the speed of the power shaft without introducing additional gearing becomes as conspicuous as in the case of aeroplanes, and the question comes up whether Renault's expedient to this end or the adoption of a worm drive will in the end prove the more acceptable method, and whether perhaps in some cases both these means for accumulating torque at the rims of the driving wheels should be combined. In the case of automobiles, the utilization of the camshaft for power would at first glance seemingly also involve the use of two flywheels instead of one, one in front on the crankshaft and another at the rear of the motor on the camshaft, for action with the clutch, but with an 8-cylinder motor these flywheels could of course be relatively light, so as to render it practicable to use them efficiently for ventilation also, and the distribution of the flywheel weight would tend to a better distribution of stresses and the avoidance of vibrations in either shaft.

Unusual Manifolds on Singer Six

(*Continued from page* 725)

The four-speed gearset is provided throughout with Timken bearings. The shifting mechanism is simple, the gear lever being mounted directly on the gearcase cover.

Two Spicer universals and a drive shaft of the same make carry the torque from this point to the rear axle, which is a Timken type of extra heavy construction. A triangular torque member is fitted. Internal and external concentric brakes 5 by 2.5 inches are used.

The fuel is carried in a 25-gallon cylindrical tank at the rear of the chassis. The filler cap is conveniently situated on the right side while in the center there is a gauge. Pressure is supplied by means of a small air pump operated from the rear end of the exhaust camshaft.

An exceptionally heavy frame design has been adopted. The depth of section is 5 inches while the flanges are 4 inches. Houk wire wheels or Schwarz wooden wheels are optional. With the latter Firestone demountable rims are furnished. Plain tread tires are used on the front while Goodyear All-weather tread tires are found on the rear.

A feature of the radiator mounting is the use of ball trunnions allowing a slight amount of movement in every direction.

Liberal springs are used and an interesting detail of their construction is the slitting of the ends, of each spring leaf, which fit into bosses on the next larger leaf, these serving as guides to prevent shifting. The cantilever spring is 54 inches long without load and 56 inches width. It has nine leaves 5-16 inches thick and 2.5 inches wide. The front springs are 35.5 inches long, 2 inches wide and nine leaves 3-16 inch thick are used.

Cole Four Averages Over 22 M. P. G. in Tests

Six 1-Gallon Economy Runs Made—Highest Average 24.4 Miles—Conditions of Tests Varied

INDIANAPOLIS, IND., Oct. 9—A Cole four averaged 22.459 miles to the gallon of fuel at an average speed of 23.6 miles per hour in six 1-gallon economy tests held yesterday and today under the supervision of the American Automobile Assn. The highest average was 24.426 miles per gallon, which was accomplished in the fifth trial, held this morning; the lowest was 20.844 miles, made in the second trial. After these tests were over, the car was subjected to a 30-minute speed trial in which an average speed of 55.63 miles per hour was maintained. All these records were made with the top down and the windshield folded back.

The object of the tests was to determine the fuel economy of the four-cylinder Cole, with and without hot air connection to the carbureter, with pressure, gravity and vacuum feed and with various passenger loads.

The car used in this test was a four-cylinder series 11-4 with a bore and stroke of 4 1-4 by 5 1-4 equipped with a Stromberg H2 carbureter, 1 1-4 inch size, Silvertown cord tires, 34 by 4 all around and Delco starting lighting and ignition units. The car weight is given as 3,230 pounds without passengers.

In order to be able to use either pressure, gravity or vacuum feed a separate 5-quart tank was carried, the main tank at the rear being disconnected. The test tank was provided with connections so that it could be used for the different systems of feeding. For gravity a measured gallon was poured into the tank and the latter fastened to the left windshield bracket. For pressure feed the same tank was placed on the running board and a hand pump used to force air into the tank. For vacuum feed the tank was left on the running board but the feed was through a Stewart vacuum tank behind the dash of the car.

Four Trials Yesterday

Yesterday four fuel economy trials were held, the first starting at 11.20 a. m. when the thermometer showed 81 degrees. The feed to the carbureter was by gravity. No hot air connection was used and the Cole, driven by engineer Charles Crawford and accompanied by another passenger, ran out of its 1 gallon of fuel after completing 22.496 miles.

This was at an average speed of 23.20 miles per hour. The fuel used was purchased of the Crescent Oil Co., is known as Coalene and was of 67 degrees Baumé. This fuel was used in all of Thursday's trials. On the first trial the car weighed 3,586 pounds complete.

On the second trial a standard gallon of fuel was fed to the carbureter under 2 1-2 pounds pressure and during this trial the weather was very unsettled, a shower and a severe drop in temperature coming in the second half. At the start of this trial the thermometer showed 81 degrees and at the finish 74. That the motor was affected by this is evident by the notometer readings which varied from 100 at the start at 12.40 p. m. to 115 at 1.05 p. m. to 100 at 1.10 p. m. and 110 at the finish. The run was made with the driver and one passenger and the engine stopped for lack of fuel at 20.844 miles after traveling at the rate of 23.38 miles per hour. The drop in mileage per gallon may be directly attributed to the varying temperatures. No hot air connection was used.

The third trial was made with the carbureter fed from the tank by the Stewart vacuum system. No hot air connection was used and with one passenger and the driver the car completed 22.028 miles on 1 gallon of gasoline, the speed of the car being 22.1 miles per hour. The temperature was slightly higher on this trial, being 90 degrees at the start and 82 at the finish and the motometer showed 110 degrees at both start and finish, due to the settled weather following the shower which interfered slightly with the previous trial.

The fourth and last trial of the day was made with seven passengers in the car, giving a total weight of 4,350 pounds. No hot air connection was used and the fuel was fed to the carbureter by the vacuum system. The Cole went around the speedway for 20.454 miles before the measured 1 gallon was exhausted and the speed for the trial was 23.40 miles per hour.

Two economy trials with hot air connections to the carbureter and one speed trial were held today and in all three events gasoline of 61 degrees Baumé was caused.

The first trial today was made at 10.10 a. m. with the carbureter fed by the vacuum system and fitted with a hot air tube leading from a stove on the exhaust manifold to the carbureter. Two passengers were in the car including driver Crawford who piloted the Cole for 24.462 miles at a rate of 24.55 miles per hour, before the 1 gallon of fuel was exhausted. The car weighed 3,650 pounds, the added weight being due to a supply of gasoline taken on for use in succeeding tests. A heavy shower caused various changes in the registrations of the motometer. At the start of the run it showed 120 degrees; at 10.32, 140 degrees, at 10.45, 120 and at the finish, 110 degrees. The air temperature was 70 degrees at both start and finish.

With Seven Passengers

The last fuel-economy run was made with the same fittings as in the previous one, but there were seven passengers in the car. The weather was by far the most favorable of the day and the 1 gallon of fuel gave out at 24.135 miles, the car having traveled at the rate of 24.75 miles per hour. The total weight of the car with passengers was 4,390 pounds and the air temperature was 72 at the start and 71 at the finish. There were, however, greater variations in the motometer readings, the start showing 150 and the finish 135.

The last event was the 1-2 hour speed trial in which Lew Pettijohn, the driver, the only one in the car, drove it at the rate of 55.63 miles per hour for 1-2 hour. The car was given a flying start and eleven laps of the speedway were covered, the total distance for the half hour being 27.815 miles and a feature of this trial was the consistency of the car. During this trial the fuel was fed to the carbureter by pressure from the regular rear tank.

Plantation Tires Make 4,000 Miles in Test

LONDON, ENGLAND, Oct. 3—Four tires made entirely from Hevea plantation para have been submitted to a 4,000-mile test under R. A. C. observation. The trial was made at the instance of the North British Rubber Co., of London and took place from June 18 to August 1. A certificate has just been issued in which the following facts have been noted:

The tires were of the non-skid type, size 895 by 135 millimeters fitted to a 60 horsepower (R. A. C. rating) six-cylinder Napier car. The car weighed 4,411 pounds and the load carried was 643 pounds, giving a total running weight of 5,054 pounds. The car was fitted with wire wheels and the inflation was 90 pounds. The trial was held over the ordinary roads met in England and Scotland. The first cover burst at 3,077 miles and was withdrawn. The second ran 4,018 miles and while no work was done upon it the casing was found to be sound at the end of the trial. The third was deflated at 3,134 miles due to a pinched inner tube and again at 3,622 miles by a blowout through the cover. With this patched the two completed the test. The fourth was deflated at 2,727 miles due to the tube being nipped in some cracks in the inner lining of the casing. A tube cover completely en-

Results of 1-Gallon Economy Tests of Cole Four at Speedway

	Trial 1	Trial 2	Trial 3	Trial 4	Trial 5	Trial 6

Weight of car empty, 3,230.
Grand average, 22.459 miles per gallon.

veloping the tube for its entire length was fitted and with this the two completed the test. In a word, three out of the four successfully completed the run of 4,000 miles.

I. A. E. Discusses War and Trade

LONDON, ENGLAND, Oct. 14—At the meeting of the Institution of Automobile Engineers held tonight, L. H. Pomeroy will present a paper entitled, Automobile Engineering and The War. Mr. Pomeroy will commence his paper by indicating the duties of the I. A. E. in connection with the war. In his paper he will bring out the necessity of having ample supplies of war material as well as efficiently equipped work shops and scientific production methods.

The most important part of this paper will deal with the substitution of British made parts and accessories for those formerly secured on the Continent, and he will propose that a committee be appointed to see what can be done in the way of promoting scientific research along the line laid down in the large Continental factories. In closing his paper he will point out the necessity of increasing the production of commercial vehicles for war purposes and also the fallacy of using passenger vehicles for the commercial work.

DETROIT, MICH., Oct. 7—At the meeting of the common council held Tuesday night, the aldermen voted 27 to 7 in favor of the maintenance of street or curb gasoline pumps, notwithstanding the opposition of the Corporation Counsel, who stated that the city had no right to grant permission for the establishment of such gasoline pumping stations upon its streets. To this one of the aldermen replied that it might be so, but, that during the last 10 years the aldermen have done many things which they had no right to do. Besides, said this good alderman, these pumps are an accommodation to the public. Which was shown by the vote.

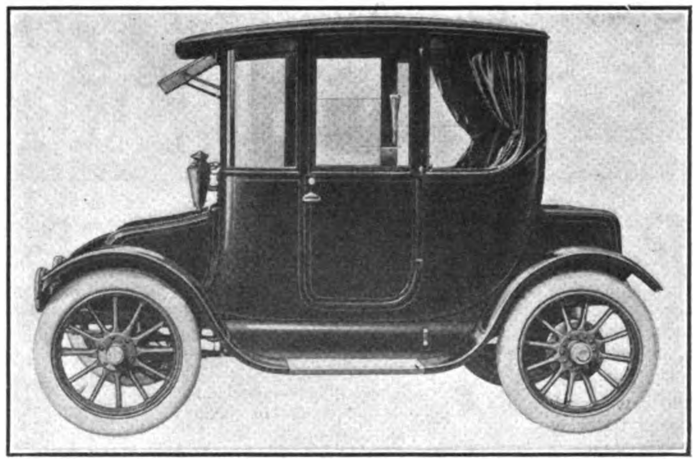
Alco Discontinues Service Station

NEW YORK CITY, Oct. 13—The American Locomotive Co. has announced that it has discontinued the operation of its automobile service station on Jackson avenue, Long Island City.

Owners of Alco vehicles in this city and vicinity requiring parts for Alco vehicles can obtain them at the service station of the International Motor Co., West End avenue and Sixty-fourth street, this city, with which company an arrangement has been made to carry a complete stock of Alco parts.

Minerva Motors Co. Takes Moline Agency

NEW YORK CITY, Oct. 13—The Minerva Motors Co., Broadway and Sixty-sixth street, this city, has taken on the agency for the Moline Automobile Co., East Moline, Ill. The Minerva company is moving from the above location to the salesroom formerly occupied by the Thomas Motor Car Co. This company has a territory which includes the Metropolitan district, Long Island, Western Connecticut, New York State as far as Poughkeepsie and northern New Jersey.



THE LATEST BAKER ELECTRIC COUPÉ

The new car weighs 1,000 pounds less than many of the electrics seen on the streets today. A unique feature of the new Baker is its seating arrangement. The front seats are of a new disappearing type and fold back out of the way when not in use. Hence, the car can be instantly converted into a three or two-passenger car.

Fafnir Co. to Sell Direct from Factory

NEW YORK CITY, Oct. 12—The Rhineland Machine Works Co., this city, reports that since a part of its business, which covers the importation of Rhineland and R. B. F. ball bearings, is so greatly interferred with by the European war, it has been arranged that the Fafnir Bearing Co., New Britain, Conn., for which it has been heretofore acting as selling agent, will market its products direct from the factory, which will in the future be the sales headquarters of the company.

D. D. Davis, who has been the Chicago manager of the Rhineland company, will make his headquarters at New Britain, and take charge of the sales of the Fafnir company. The Rhineland company will continue to assist in the sale of Fafnir bearings in conjunction with the sale of its stock of imported bearings, and such R. B. F. and Rhineland bearings as are now coming in from Europe.

Merchandising Reforms at Truck Convention

(*Continued from page* 709)

"The manufacturers alone can control the evil of cut prices, and makers can only continue in the industry by honestly placing their list prices at a reasonable figure over and above all manufacturing, administration, sales and overhead costs, and then maintaining these prices." In this sentence J. C. Millman, of the Stegeman Motor Car Co., outlined his conception of his topic "Reforms Needed in Merchandising Motor Trucks."

Mr. Millman decried extravagant discounts to dealers from inflated list prices to permit dealers to cut retail prices as a sales inducement, and stated that overproduction and inexperienced salesmanship were largely responsible for cut prices in the commercial vehicle industry.

Inefficient salesmanship is another evil. It is bred by inexperience and incompetence, and is a strong factor in the creation of the price-cutting evil. The evil of improper ratings and extravagant overload claims is disappearing. He advocated the standardization of load capacities for given specifications and referred to the practice of overload guarantees as a dishonest practice, resulting in cheating of the buyer who in his simplicity endeavors to employ his truck in defiance of natural and mechanical laws.

The trading evil, the practice of taking in used trucks as part payment on new vehicles at inflated valuations, was suggested as soluble by the discontinuance of appraisal by the dealer in the new truck, and substitution therefor, appraisal at a minimum figure by the owner and sale by the dealer for the best figure above such minimum possible. Another suggestion that struck at the root of the evil was that of restricting the creation of the used car supply by regulating and restricting the application of trucks where their adaptability to the conditions of use is iu doubt, thus permitting the user to keep his truck in service, instead of attempting to trade it back for one better suited after he has learned by experience that the salesman had made a faulty recommendation in order to compete in price with his competitors.

Mr. Millman did not condemn time payments, but advocated their restriction and placing upon a sound business basis. He stated that he considered any first payment of less than one-third unsafe, and that there was no reason why the manufacturer should turn banker, but that the matter of financing the sale be left between the buyer and his bank. There was no reason why the manufacturer should be expected to take risks that the banker will condemn. The knocking evil was not taken seriously.

FIRESTONE Uses 12,000 Tons of Steel—C. C. Carlton, head of the rim department of the Firestone Tire & Rubber Co., Akron, O., quotes figures regarding the company's rim plant, in which 12,000 tons of steel were converted into rims during the past year. It required 150,000 square feet of floor space and almost 400 mechanics to handle this material. Sixteen electric welders were required, one of them especially constructed to handle stock 14 inches wide. The storage space required to carry the stock of raw steel necessary to insure prompt handling of all orders amounted to 15,386 square feet. It requires about 1,000 box cars to carry away the season's output of rims. If these cars were made up into one train they would stretch out for almost 8 miles. Firestone rims will be used exclusively during the 1915 season by forty-nine automobile manufacturers.

Warren Rubber will Add—The Warren Rubber Co., Warren, O., will begin at once the erection of a large addition to its factory.

Wood Co.'s Motor Truck Plant—J. L. Ware, manager of Wood Motor Vehicle Co., plans to erect a motor truck factory in St. Paul, Minn.

Hupp's Dynamometer Test Dept.—The Hupp Motor Car Co., Detroit, has recently installed a dynamometer test department at an expense of over $75,000.

Manufacturing Piston Rings in Vancouver—Harmington & Diggs are arranging to open a factory in Vancouver, B. C., for the manufacture of piston rings.

Sphinx Operations Increased—Operations at the new plant of the Sphinx Motor Car Co., York, Pa., are being gradually increased, and within the next 30 days the factory will be working to capacity.

Purchases Michigan Top Equipment—The A. C. Knapp Co., Detroit, Mich., manufacturer of tops, hood warmers, slip-covers, trimmings, etc., has purchased the entire equipment of the Michigan Top Co.

Large Maxwell Shipment to California—One of the largest shipments of automobiles ever received on the Pacific Coast was the trainload of Maxwells delivered to the Lord Motor Car Co., Los Angeles, southern California distributer.

Adamson Machine Will Add—Adamson Machine Co., Akron, O., maker of automobile tire molds, will enlarge its plant with an addition 80 by 100 feet, to be used for a foundry. Some new machinery will be installed.

2,200 Fords Assembled Since March—A statement just issued by the Ford factory branch in Seattle, Wash., shows that 2,200 Ford automobiles worth $1,281,347 have been assembled and completed in Seattle since last March, when the $300,000 plant was completed.

Hill Co. Will Add—The J. Lawrence Hill Co., Cambridge street and Park avenue, Rochester, N. Y., manufacturer of carriages and automobiles, will continue the manufacture of its present lines and will not produce batteries or their parts, as has been reported elsewhere. It will add to its factory equipment.

Berry Pump Co. Secures Factory—The Berry Automobile Pump Co., Detroit, has been incorporated with a capital stock of $10,000 by H. J. Berry, W. W. Gunn and Charles Redder. The new company, which will engage in the manufacture of pumps and other devices, has already secured factory quarters.

Anderson's New Repair Plant—Because it interfered greatly with the regular work at the factory and also occasioned much congestion the Anderson Electric Car Co., Detroit, Mich., has decided that all the repair work and service department will be taken care of hereafter from the salesroom and service station at 687 Woodward avenue.

Die Castings Plant in Madison.—The Berkely-Fourness Co., organized at Madison, Wis., several weeks ago, to manufacture die castings, stampings and appliances, including a regulator for motorcar lighting systems, has established a plant at 619-621 Williamson street, Madison. The concern is also bringing out an improved lock-nut for motor car and railroad work.

Braender Rubber Enlarges Factory—The Braender Rubber & Tire Co. is erecting a large addition to its present factory at Rutherford, N. J., which will increase the capacity of its plant to approximately 1,000 tires and 1,000 tubes per day. The new building has been designed along the most up-to-date lines of factory construction. It will be 141 feet wide by 129 feet long and built entirely of brick. It will be four stories high, fireproof throughout and equipped with all the latest time and labor-saving machinery for tire and tube making.

Edwardsville Exploiting New Car.—Edwardsville, O., has a new industry, an automobile manufacturing concern, well under way. The capital stock is $100,000, of which $50,000 has been paid in. The company is building a factory 550 feet long and 150 wide in the southern part of town, and expects to turn out 5,000 machines a year. The company is incorporated as the American Standard Automobile Co., and its machines will be known as American Standards. Six types of cars, to retail at $1,375, $1,000 and $750, will be manufactured and known as American Standards. Henry Trares, Jr., Judge John E. Hillskotter, Peter Bernhardt, of Edwardsville, and H. B. Gardner, of Chicago, are directors. C. H. Gerling, of Edwardsville, and Louis Karsch, of St. Louis, are large stockholders.

The Automobile Calendar

Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.

Mar. 9-15	Des Moines, Ia., Show, C. G. Van Vliet.
Mar. 14	San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

The Week in  the Industry

McCULLA Goes to Knox—W. R. McCulla, who has been with the Packard Motor Car Co., Detroit, Mich., for several years as assistant research engineer, has resigned to become assistant chief engineer of the Knox Motor Co., Springfield, Mass.

Brown Resigns—F. L. Brown, formerly manager of the Stutz Motor Car Co., of Connecticut, with headquarters in Hartford, has severed his connection with that concern.

Worfolk Regal Advertising Manager—The Regal Motor Car Co., Detroit, has appointed C. E. Worfolk as its advertising manager.

Tisch Advertising Manager — The Paige-Detroit Motor Car Co., Detroit, Mich., announces that Roy Tisch has been appointed manager of its advertising department.

Gray Apperson Branch Manager—W. C. Gray has been appointed manager of the Apperson Bros. Automobile Co., Detroit, Mich., established at 1581 Woodward avenue.

Douglas Joins Stewart-Warner—S. A. Douglas, formerly Jones speedometer sales manager for the Johns-Manville Co., has taken a position as special factory representative for the Stewart-Warner Speedometer Corp., Chicago, Ill.

Butler Succeeds Clute—L. L. Butler has taken over the management of the Vancouver Island Motor Car Co., Ltd., Victoria, B. C., replacing Mr. Clute, who has resigned.

Mann Bowser District Manager—W. M. Mann has been appointed district manager in Texas for S. F. Bowser & Co., Fort Wayne, Ind. His offices will be located in the Commerce Bldg., Dallas, Tex.

Woods Goes to New Haven — T. G. Woods, who has been connected with the White company's sales forces at Boston and Providence, has gone to New Haven to act as commercial sales manager for the White agency in that city.

Avery Forms Advertising Agency—M. LeRoy Avery, who until recently was advertising manager of the Regal Motor Car Co., Detroit, Mich., and F. W. Reed, an advertising man, have organized the Avery-Reed Advertising Agency.

Snow Appointed Manager—H. M. Snow has been appointed manager of the branch just opened in Copley square, Boston, Mass., by the Ford company, and which will eliminate the sub-branches in that city. The branch will be under the control of the big wholesale distributing plant at Cambridge, Mass.

Coulter Joins Firestone—C. W. Coulter, formerly with the Western Rubber & Supply Co., of Pasadena, Cal., has joined the Firestone Tire & Rubber Co.'s branch at Los Angeles and is to handle the trade of Santa Barbara and Ventura counties.

Allen Oldsmobile Montreal Manager—W. A. Allen, lately manager of the Pope Hartford Motor Co. of Canada, has been appointed manager for the Gordon Motor Co., which handles the Oldsmobile cars in Montreal, Que. Larger premises and show rooms have been taken at the New Birks building, Montreal.

Recent Minneapolis Changes—K. E. Corrington is the new district salesmanager for the Empire Tire & Rubber Co., headquarters Minneapolis, Minn. R. E. McComas, who came to Minneapolis a year ago from the Chicago office of the Woods Electric Car Co., to the Owl Electric Garage Co., agent for the Woods car, has taken an interest in the company and is now secretary and manager. J. N. Johnson is president, W. A. Simonson is vice-president and A. M. Wintheiser is treasurer. The P. J. Downes Co., representative of the Jeffery car, will push the truck department and have added two men to the branch work, H. B. Foley of Cleveland and F. M. Trew of Minneapolis.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

California

LOS ANGELES—L. A. Automobile Works; capital, $10,000. Incorporators: Thomas E. Mitchell, John Stintin and others.

SAN FRANCISCO—Foard Starter Mfg. Co.; capital, $20,000; to manufacture motor cars and supplies.

Florida

JACKSONVILLE—Florida Tire Co.; capital, $25,000; to deal in motor cars, tires and supplies. Incorporators: George Adams, George M. Hopkins and Claude M. Shine, all of Jacksonville.

Illinois

CHICAGO—Shasta Machine Co.; capital, $21,000; to manufacture motors, etc. Incorporators: Edward J. Carey, Helen Dias and Charles C. Mull.

CHICAGO—Carman Mfg. Co.; capital, $2,500; to manufacture and deal in motor car parts and accessories. Incorporators: Edward L. Archibald, Richard V. Megary and Charles R. Brown.

EDWARDSVILLE—American Standard Automobile Co.; capital, $100,000; to manufacture and deal in motor cars. Incorporators: P. Berhardt, C. H. Gerling and L. Kirsch.

ROCKFORD—C. B. Williamson Corporation; capital, $2,500; to manufacture and deal in motor vehicles, accessories, supplies, etc. Incorporators: C. B. Williamson, F. C. Gleasman and O. V. Williamson.

Iowa

DES MOINES—Successful Motor Sales Co.; capital, $25,000.

MUSCATINE—Muscatine Motor Car Co.; capital, $25,000; to buy, sell, rent, lease and deal in motor vehicles and operate a garage and repair department. Incorporators: F. C. Vetter, J. G. Campbell, C. M. Weber, R. K. Smith, W. F. Bishop and G. A. Chaudoin.

Kentucky

COVINGTON—Madison Motor Car Co.; capital, $5,000; to deal in motor cars. Incorporators: E. J. Moore, Jr., Charles E. Madris and Maria Moore.

Maryland

CAMBRIDGE—Chersaw Motor Car Co.; capital, $5,000. Incorporators: R .B. May and others.

Massachusetts

BOSTON—E. A. Gilmore Co.; capital, $20,000; motor cars. Incorporators: Earnest A. Gilmore, Augustus C. Gilmore and Arthur P. Teele.

Missouri

KANSAS CITY—Kansas City Auburn Auto Co.; capital, $8,000. Incorporators: R. W. Gall, B. P. Gall and E. H. Farmsley.

Ohio

AKRON—Smith Motor Co.; capital, $5,000; to deal in motor cars. Incorporators: E. D. Smith, E. E. Smith, F. W. Hachtel, W. S. Nicodemus and Mary Distel.

CLEVELAND—Cleveland Motor Car Sales Co.; capital, $25,000. Incorporators: M. D. Bramley, Harry C. Walker, Arthur Hutt, M. Barthelman and J. C. Simon.

NEWARK—Blair Motor Truck Co.; capital, $100,000; to manufacture motor trucks. Incorporators: J. F. McCune, C. A. Smith, R. W. Smith, C. H. Spencer and W. S. Weiant.

Oklahoma

MUSKOGEE—Muskogee Buick Sales Co.; capital, $3,000; to deal in motor cars. Incorporators: Hugh Swift, Fay H. Swift and W. T. Wisdom, all of Muskogee.

South Dakota

MITCHELL—Motor Mart; capital, $2,500; to deal in motor cars. Incorporators: M. P. Fugel, C. A. Allison and Mary E. Allison.

SIOUX FALLS—Cadillac Sales Co.; capital, $25,000; to deal in motor cars. Incorporators: D. P. Fargo, C. M. Fargo and M. F. Beveridge, all of Sioux Falls.

Washington

EVERETT—Paddock-Fowler Auto Co.; capital, $10,000; to deal in motor cars. Incorporators: W. R. Paddock, G. W. Fowler, Harry B. Gay and A. C. Edwards, 211 Realty Building.

Wisconsin

LACROSSE—Moll-Savage Co.; capital, $10,000; to deal in motor vehicles, etc. Incorporators: A. L. Moll, M. D. Savage and George H. Gordon.

GARAGES AND ACCESSORIES

California

RIVERSIDE—Fairmont Garage & Machine Works; capital, $50,000. Incorporators: A. A. Gamble, W. W. Gamble, R. E. Gamble, L. W. Gamble and Dora V. Gamble.

SAN FRANCISCO—Ford Starter Mfg. Co.; capital, $20,000; to manufacture motor car starters. Incorporators: E. P. DeBerry and W. L. Hoyt, both of Berkeley; F. L. Dreber.

Delaware

WILMINGTON—Hester Tire & Rubber Co.; capital, $300,000; to manufacture tires, tubes, etc. Incorporators: B. H. Friel, L. A. Brownhill and G. M. Purcell.

Illinois

CHICAGO—Boiler Insulated Wire Co.; capital, $20,000; to manufacture and deal in motors, electrical appliances, machinery, etc. Incorporators: Peter Boiler, William N. Boiler and W. H. Bentley.

PEORIA—National Electric & Supply Co.; capital, $75,000; to manufacture electrical and motor car supplies. Incorporators: Ralph V. Miller, Theodor E. Bass and H. H. Moody.

Indiana

INDIANAPOLIS—Indiana Garage Co.; capital, $2,000. Incorporators: Roger Kenny, H. N. Siefert and Oscar Siefert.

INDIANAPOLIS—Indiana Taxi Co.; capital, $2,000; to conduct a motor transit and taxi business. Incorporators: R. Kenney, H. N. Siefert and O. Siefert.

Massachusetts

BOSTON—American Motorists' Protective Association; capital, $50,000. Incorporators: Frederick L. Keith, Richard R. Snow and Alfred P. Goodell.

WORCESTER—Stoddard Rubber Co.; capital, $60,000. Incorporators: Charles A. Stoddard, F. Madge Stoddard and Samuel L. Cowitz.

Michigan

DETROIT—Addison Garage Co.; capital, $8,000. Incorporators: W. F. Malow, George C. King, Edward E. Esper and W. T. Phillips.

Minnesota

MINNEAPOLIS—Automobile Trail Blazing Assn.; capital, $50,000; to mark and blaze trails through America and sell guide books. Incorporators: A. L. Meigs, Ira Farr and L. C. Meigs, all of Minneapolis.

MINNEAPOLIS—Tire Supply Assn. to Western Automobile Supply Co.

Missouri

ST. LOUIS—Best Service Auto Truck Co.; capital, $30,000; to conduct a general motor vehicle business and operate a garage. Incorporators: E. H. Abadie, E. E. Scott, Lewis Perry, Robert B. Snow and E. G. Curtis.

New Jersey

NEWARK—The Gasolene Protectometer Co.; capital, $100,000; to manufacture gasolene and other protectometers. Incorporators: W. Reppein, C. A. Alliston and L. Olschewski, all of Newark.

NEWARK—S. & S. Starter Co.; capital, $40,000; to manufacture starters for automobiles. Incorporators: W. M. Golden, Jr., Brooklyn, N. Y.; A. L. Whitmer, Newark; J. W. Shinholser, Bretton Hall, N. Y.

New York

BROOKLYN—Russian American Rubber Tire Works; capital, $100,000. Incorporators: Rose Miller, 477 Stone avenue; Isidore Kelner and Sruel Bilik, both of 1549 Pitkin avenue.

BUFFALO—Davis-Rae Oil Co.; capital, $5,000; to sell oils and other motor car sundries. Incorporators: Frank B. Rae, 713 Park avenue, Rochester; Albert H. Davis and Lillian E. Davis, both of 1018 Main street.

NEW YORK—Advertising Auto-Car Co.; capital, $100,000. Incorporators: Rocco J. Cipriano and Antonio DiGiorgi, both of 107 Broad street; Julius J. Lusardi, Raritan, N. J.

NEW YORK—Drubin Funeral Car Co.; capital, $10,000; motor cars for funerals. Incorporators: Arthur W. Drubin and Herman Drubin, both of 127 West 26th street; Alexander Schneeweiss, 1941 7th avenue.

POUGHKEEPSIE—S. L. S. Electric Co.; capital, $30,000; to manufacture storage batteries and automobile accessories. Incorporators: A. Bolognesi, Highland; A. M. Sherer, Poughkeepsie; J. B. Ball, Milton.

Ohio

CINCINNATI—Palmer Automatic Gear-Shaft Co.; capital, $10,000; motor car supplies. Incorporators: R. P. Palmer, S. R. Palmer, W. H. Palmer, C. P. Lindsay and G. W. Frank.

Oregon

PORTLAND—Electric Service Vehicle Co.; capital, $25,000. Incorporators: A. E. Blair, F. S. Robinson and R. A. Leiter.

Texas

SAN ANTONIO—Alamo Packard Auto Livery Co.; capital, $4,500; to operate a motor livery. Incorporators: Jennie D. Tucker, Arthur M. Tucker and George T. Tucker.

Utah

OGDEN—American Auto & Transfer Co.; capital, $25,000; to operate a motor transit line. Incorporators: P. W. Madsden, Ogden, and others.

Washington

SEATTLE—Western Auto Subcasing Co.; capital, $100,000. Incorporators: Hiram S. Nettleton and Marius S. Williams; Wright, Kelleher & Caldwell, 402 Burke Building.

CHANGE OF NAME AND CAPITAL

Illinois

CHICAGO—Kloeber Motor Co. to Exchange Motor Co.

ROCKFORD—Barnes Motor Sales Co. to Williamson Motor Co.

New York

BUFFALO—Lumen Bearing Co.; from $200,000 to $300,000.

Ohio

CLEVELAND—Overland-Garford Sales Co. to Overland-Cleveland Co.

Accessories for the Automobilist

ROTHERMICH Combination Light—A simple combination tail light, signal light license pad illuminator and holder is announced by A. P. Rothermich, St. Louis, Mo. This device consists of a regular tail light with a glass and metal case around it, this case being attached to the license pad by two irons. The construction is such that by moving a lever, within easy reach of the driver, the case containing the tail light may be moved. When set in one position the word SLOW faces the car behind. as shown in Fig. 1, and in the same illustration the other position is shown in which the warning signal is turned down. However, the license pad is illuminated, when the word "slow" is turned down, by light passing through the signal glass. When set as shown at the top of the illustration the pad is illuminated by a transparent glass at the bottom of the case. This signal affords a simple means of warning the driver of a car that a turn is to be made or that the car will make a sudden stop.

Fig. 1—Rothermich combination light

Bremer Pump Nipple—Motorists who are in the habit of holding the tire pump nipple in place over the valve stem will be interested in a new nipple which does not require attention once it is set. The new device is a product of the Bremer Cycle Co., Milwaukee, Wis., and is said not to leak when once properly set over the stem. The parts of the nipple. which is shown in Fig. 2, are made of brass and steel. There are four parts, two of which form the body and the means of adjustment, one to receive the lead from the pump, and the other which slips over the valve stem. The nipple sells for 50 cents.

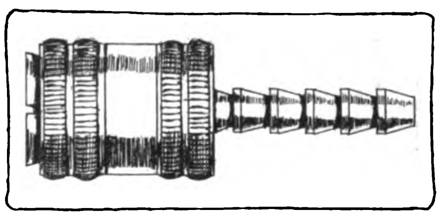

Fig. 2—Bremer pump nipple

Scott Tread Economizer—An arrangement to make possible the using of old tire treads, as outer treads for other tires, has been patented and placed on the market, under the name of the Scott Economizer, by the Scott Economizer Co., Bromford Lane, Erdington, Birmingham. England.

The tendency of former arrangements of this kind to cause the outer covering to creep has been overcome by this system. Two chains are passed around the circumference of the wheel. one on the outside, one on the inside. These chains may be tightened by a screw adjuster, and springs are interposed on each chain to keep up the tension should the tire become slightly deflated. V-shaped links are attached to the old tread, acting as the outer cover, and from which, of course. the bead has been cut off, by two small bolts and nuts; consequently they can be removed and attached to another cover when necessary. This makes the device applicable to any number of old covers, and to any size, as the chain can easily be lengthened or shortened.

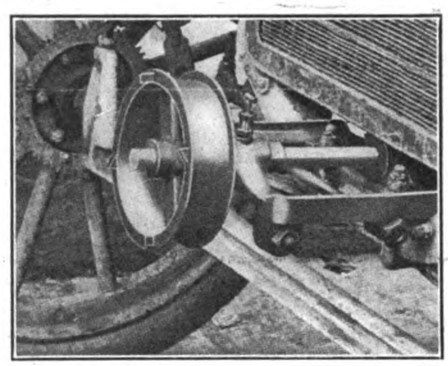

Fig. 3—Ruff-Ford power transmitting attachment

Fitting the old cover over the new can be done by one man in 5 minutes. A kink is put in the sound cover by bending it against the operator's knee. It is then folded and placed inside the economizer cover, the kink gradually worked out by pressing with the foot, and finally by bouncing the combination on the floor. The two covers are then put on the wheel in the ordinary way, the tube inserted, chains adjusted and the tire pumped up. All can be done within 45 minutes, it is claimed.

Ruff-Ford Power-Transmitting Attachment—Power for driving machine tools, pumps, etc., can be obtained from a Ford by means of the attachable pulley and bracket shown in Fig. 3, which is manufactured by the Ruff Tire Trading Co., 50 William street, Newark, N. J. The price of the attachment is $20.

Go Motor-Speeder—In the device shown in Fig. 4 carburetion is aided by introducing a stream of hot air into the main passageway of the intake manifold. This is heated by a coil of pipe passing around the exhaust pipe. The amount of air flowing through the coil is regulated by a valve that is connected up to the throttle. The device is manufactured by the Go Motor-Speeder Co., 318 Flint avenue, Three Rivers, Mich., and sells for $10, ready to install.

Rochester Fanhorn—A combination radiator fan and diaphragm horn has been announced by the Rochester Mfg. Co., Rochester, N. Y., the feature of this device being that the rotation of the fan operates the horn. The horn is controlled by a hammer, which normally is out of contact with the diaphragm of the horn, but upon pressure of a button it is brought into contact. The greater the pressure on the button the louder the sound emitted from the horn, and the higher the engine speed the greater the volume of sound. The tone can be made loud or soft, to suit conditions. On a country road, for example, the loudest note would be more appropriate, whereas in the city a more subdued tone would be advisable. The elimination of the care necessary with a separate horn unit and the saving due to mechanical operation are two features of this Fanhorn, as it is called.

Another product of this concern is a combination gasoline gauge and filler cap fitting. This bringing together of two units with two distinct functions into one unit of two functions is the feature of the instrument. The indicator of the gauge is in the form of a ring provided with numerals, these numerals being visible through a small glass window at the front of the instrument. The numerals register gallons of fuel.

The inside of the filler tube just above the indicator is provided with a protecting grill to guard the indicator and the entire construction allows ample space for the free passage of gasoline to the tank. It is designed in sizes and types for use either with rear mounted tanks of the pressure or vacuum system, or for tanks carried in the cowl. In the latter, the instrument is furnished with an escutcheon plate to trim the gauge upon the instrument board and is furnished either with a straight tube, when the angle of the gauge, which is decided by the shape of the tank, will permit, or with an upturned tube, when it is desired to bring the opening nearer vertical for convenience in filling. It is also

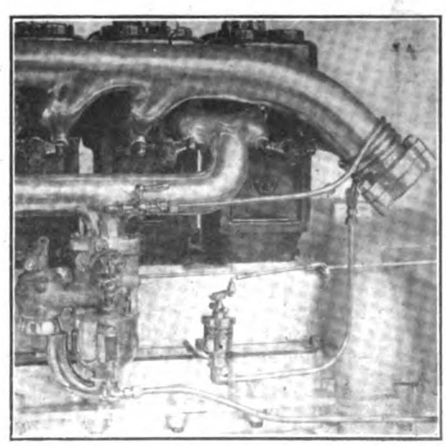

Fig. 4—Go Motor-Speeder for heating the charge

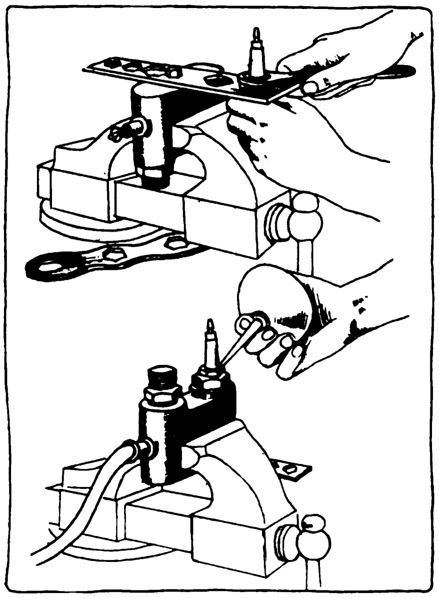

Fig. 5—Method of using Cico spark plug fixture

furnished with a flanged base for screwing to the tank flange or collar instead of the threaded base shown. The standard finish is black.

Cico Spark Plug Fixture—A handy garage tool for use in cleaning, repairing and testing spark plugs has just been brought out by the Champion Ignition Co., Flint, Mich. This tool consists of a cast-iron box, as shown in Fig. 5, with two openings at one end to receive spark plugs, and an arrangement on the other to hold a plate for securing plugs when they are desired to be taken apart. The upper illustration shows the plate in position and a plug about to be disassembled. The holes in the plate are for different size plugs. Two wrenches also are supplied, which will fit the bushings on all standard plugs. The lower illustrations show how the tool is used in testing plugs. For this operation the box is reversed in the vise and the plug inserted into one of the openings of the box, which now is made to act as a compression retainer. Connection is made with a tire pump or similar source of compressed air and after the air has been pumped into the box the conventional leak test is made. This consists in squirting a little oil over the plug joints and should bubbles appear the plug is leaky.

Goodyear White Vulcanizing Cement—The Goodyear Tire and Rubber Co., Akron, O., has recently put on the market a white vulcanizing cement after testing it thoroughly in its repair department. This new product has the advantage that the repair is the same color as the rest of the tire whereas the dark-curing cement formerly used made the repaired spot darker than the original tread.

In the most recent issue of the No-Rim-Cut News, the house organ published by this company, some good advice to repairmen is given regarding the vulcanizing of treads: "Sand bags may be used instead of air bags, in curing tread cuts. Internal pressure only is needed against the tread in such repairs. For each sectional mold size one sand bag and one steel bar will be needed. The bag should be of heavy canvas, shaped like a common salt bag and filled loosely, not packed, with fine sand. The steel bar should be of 1-inch section about 1 foot long, and curved so it will fit within the mold.

"The sand bag is placed within the casing, the casing dropped within the sectional mold, and the steel bar laid along the sand bag, concave side up. The clamp screw is screwed on the mold against the center of the bar. This spreads out the sand bag and supplies the necessary pressure against the tread. It is a good plan to drill a hole or slot in the bar so that the clamp screw can get a grip."

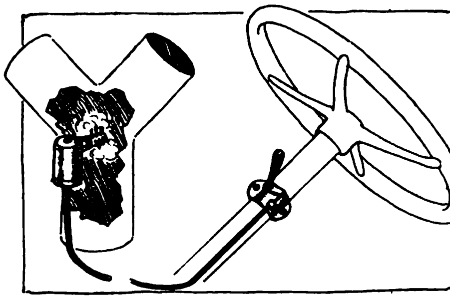

Fig. 6—Jumbo gasoline economizer

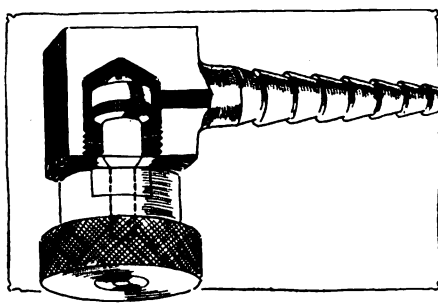

Fig. 7—Edelmann automatic air chuck

Jumbo Gasoline Economizer—E. Edelmann & Co., 225 W. Illinois street, Chicago, Illinois, is offering the simple economizer shown in Fig. 6 for $2.50. It consists of a steering-wheel controlled air valve that allows more or less air to enter the manifold as desired. The valve is operated from the wheel by means of a small lever and a flexible cable suitably encased. It is stated that it can be attached in ten minutes.

Edelmann Automatic Air Chuck—An improved form of air chuck for connecting the pump hose to the tire valve is illustrated in Fig. 7. It is manufactured by the E. Edelmann & Co., 225 W. Illinois street, Chicago, Ill., and the Eastern agent is Asch & Co., 1779 Broadway, New York City. To operate this device it is merely necessary to force it over the valve stem. No screwing is required. When it is removed, the valve closes automatically until again used. All parts are renewable. It sells for $1.00.

Alpha Grease—High melting point petroleum greases suitable for the lubrication of bearings subjected to intense heat or bearings affected by water are manufactured by the Albany Lubricating Co., Adam Cook's Sons, proprietors, 710 Washington street, New York City. These greases are sold under the trade name Alpha and are of especial value for clutch grease cups, or water pump grease cups where the grease is liable to melt and allow a leakage of water.

Mabey Electric Patching Tool—An electric patching tool for use in vulcanizing small cuts and holes in tires is announced by the Mabey Electric & Mfg. Co., Indianapolis, Ind. It is simple in construction and consists of a hand grip with a metal terminal at one end for centering the heat for vulcanizing. The Mabey vulcanizer tool is operated from a 6 or 12-volt circuit and incorporates an automatic temperature regulator. It is 6¼ inches long, consumes ¾ ampere and is sold for $2.75 complete with 8 feet of lamp cord and vulcanizing rubber.

Lubcke Frameless Windshield—An uninterrupted view is the goal aimed at by the windshield brought out by Charles Lubcke, M.E., 320 Fremont street, San Francisco, Cal. The new design is shown in Fig. 8, where it will be noted that it is made in two pieces hinged at each end. The lower half is braced and the few metal fittings required are made from dull-finished brass. The bottom clamp is a felt insert to give a cushioning effect. It is stated that the windshield has sufficient mechanical strength to resist any stress.

American Valve Grinders—Adjustable to any size valve, of which they will grind a set in thirty minutes, the American Adjustable Valve Seating and Facing Tools, of which there are two, are being placed on the market by the American Valve Tool Co., of Stamford, Conn., to save motor car owners the $3.00 to $5.00 charges which they pay for this service and the loss of time consequent. The set as shown in Fig. 9 sells for $10.00.

Canvas Garages—What is probably the most portable of portable garages is the tent garage manufactured by the Couch Brothers Mfg. Co., Cincinnati, O. These are made in eight different sizes and are of six different grades. The prices range from $41.35 for a 9½ by 12-foot, 8-ounce army duck, to $119.88 for especial United States Government tan duck, which is rain and mildew proof. The garage tents may be used as a permanent housing for the car, and as they make a very small package when packed up, tourists can take their garages with them on trips.

VOL. XXXI NEW YORK—THURSDAY, OCTOBER 22, 1914—CHICAGO No. 17

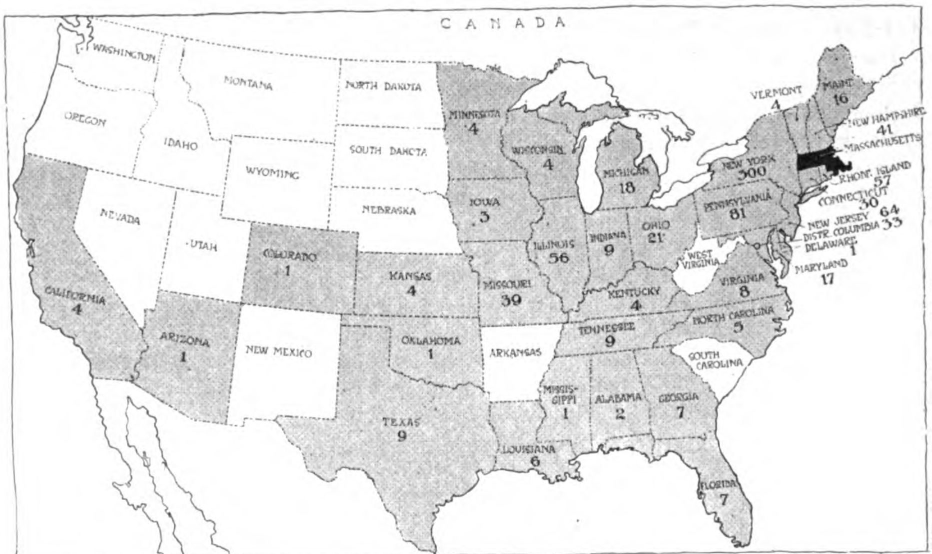
The AUTOMOBILE

New England–Tourists' Realm

72,790 Visiting Cars, from Nearly Every State in the Union, with 129,400 Owned in New England Bring a Revenue of Over $8,000,000

By James T. Sullivan

BOSTON, MASS., Oct. 1—If any-one were to state casually—having in mind that these are supposedly not very good times for business—that in 2 months this summer, July and August, automobilists spent more than $8,000,000 while touring in New England it would seem like a very exaggerated statement. Yet conservative figures place the sum at that amount. When one figures that there were more than 202,000 cars on the highways of that section in 2 months, or some 12 per cent. of the entire registration in the United States, some credence must be given to the amount spent.



Shaded portions of the map indicate states represented by automobile tourists in New England during the past summer, figures giving the number of cars

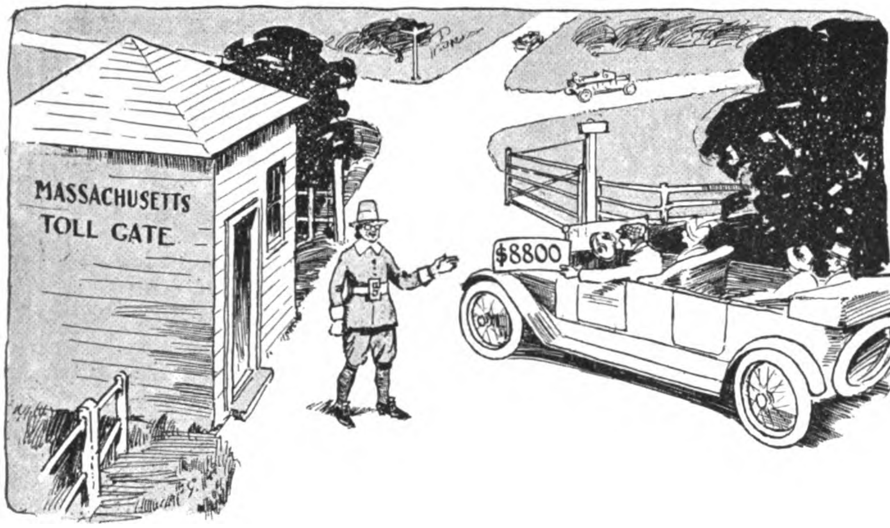
129,400 Cars in New England

On July 1, admittedly the beginning of the touring season, according to THE AUTOMOBILE, there were registered in this country 1,548,350 cars. Now it is not stretching a point too far to say that in the next 2 months the registrations all over the United States put the figures close to 1,600,000. Taking that for granted the registrations in the New England States totaled 129,400, or about 8 per cent. of the total registration. By a process of deduction to be explained later some 72,790 visiting cars toured that section, making a total of 202,190, or about 12 per cent. of all the cars owned in this country.

Giving each car an average of three passengers it makes a total of 606,570 who were making trips. It is not putting the figure too high to say that each car used up at least $1 worth of gasoline and oil a day. No account is taken of the money spent for meals, hotels, etc., for the writer wants to keep his figures as conservative as possible. Certainly many cars showed a daily expenditure of its occupants, even if only three, for car and occupants together as high as $15 a car or more. So when the figure is held down to $1 it more than counterbalances any idea of exaggeration.

$8,491,900 Spent on Tours

Therefore taking the 129,400 cars owned by New Englanders, and which were daily on the road for 60 days, it gives a total of $7,764,000 at the $1 a day average. Adding to that the 72,790 visitors, and allowing that they spent at least 10 days on an average here, and it gives $727,900 more, a total of $8,491,900 for the summer. That is the reward New Eng-



Owners of cars from other states contributed $8,800 in license fees to the state of Massachusetts alone during the past summer

land is reaping for opening to tourists her shore resorts, splendid boulevards and state highways. And if there is one real convincing fact, that proves more than any other that New England is the Mecca for motorists yearly, it is found in the figures that show that in 3 years, out of all the states and territories comprising the Union only ten were not represented in the list of non-resident registrations in Massachusetts, and these non-residents registered were those who came here to stay for a period long enough to take out such a license. In that same period eight foreign countries were represented. The ten unrepresented states were in the Far West where motoring has not taken a very strong hold.

A 1-Day Census in Maine

However, it is the figures that count. Maine now has approximately 14,000 pleasure cars registered. The Maine State Automobile Assn. officials take a great interest in motor affairs, and a year ago a census was taken of cars on various roads. This year there was other important work on hand and it was not possible to give the time to a similar census. But just to get some data on 1 day in August, not a Sunday or holiday, a man was stationed for 2 hours on the road several miles from Portland to make some statistics. In that time he noted 125 cars coming into Maine and 115 leaving, all non-resident machines. There were about 150 Maine cars passing in both directions also. Taking that as a basis, and allowing that it was for 2 hours only, it gives a total of 240 foreign cars. Multiplying that by 60 gives 14,400 for 2 months.

New Hampshire Is Popular

New Hampshire had 1,157 non-residents registered in 1913 and 1,200 this year up to September 1. That state watches visitors carefully, and they have but 10 days to remain in the state without taking out a license. As it is a very popular touring section set in a place where it is bordered on all sides by states having many motorists it is not putting the average too high to say that for each one registered there were at least twenty-five who went through without registering. That would give a total, including the registered ones, of 31,300. For Vermont it would not be over-estimating the figure to say that 50 per cent. of the New Hampshire visitors crossed over into the other State, it being so near, and has so many attractions. That would give some 15,600 cars. From New York State with its immense registration and other New England States it is not claiming too much to say that some 4,400 cars went in and out, giving a total of 20,000. The non-resident law is so broad that few take out registrations and no separate list is kept of them. Vermont has about 8,000 cars registered.

Massachusetts is recognized as the pioneer touring place because of its splendid roads built for many years, and its fine summer attractions. So it is not surprising that its figures would exceed all others. To get to some of the other states the Bay State must be traversed. Until this year the law allowed but 10 days for motorists to stop without registering. This year when many visitors came here they found that the law had been changed to 30 days. At first it seemed a very hospitable act. But it had its joker. The non-resident with 10 days only could register for 3 months at a reduced fee. This year, if he remained more than 30 days, and many of them did, it meant paying an entire year's fee. It created a rumpus. At first it was thought that the total of non-residents would dwindle, but they did not. On the separate list this year, those registering for 1 month, there were only thirty-nine, but the total for all non-residents who had to pay the yearly fee ran up to 880. This was an increase of 140 over the same period in 1913.

Now it is well known that for every car registered to stay 2 or more months there are some fifty cars that come in and out of the state for short periods. This year they seemed more numerous than ever about the streets and around the hotels. On Sundays there were constant streams of them heading over our boulevards. So multiplying the 880 regulars by the fifty transients and one gets, including the 880, a total of 44,880. The state registrations show about 60,000 pleasure vehicles.

Connecticut, being the entering state from southern New York and the South, many of the visitors to New England pass through there. Others go through there leaving New England. Then there are many others who go from New York for brief visits to summer homes along the Sound, and others from Rhode Island. If we take 50 per cent. of the Massachusetts visiting cars it gives 22,440. And certainly from New York and Rhode Island during the 2 months there are at least 2,560 to make a total of 25,000. The state registration is some 23,500. Rhode Island has a lot of shore re-

Non-Resident Tourists Visiting Massachusetts

	1912	1913	1914		1912	1913	1914
Alabama	2	0	2	North Dakota	0	0	0
Arizona	0	0	1	Ohio	40	29	21
Arkansas	0	0	0	Oklahoma	0	0	1
California	7	4	4	Oregon	0	0	0
Colorado	2	0	1	Pennsylvania	78	80	81
Connecticut	43	43	30	Rhode Island	42	42	57
Delaware	0	2	1	South Carclina	0	2	0
Florida	3	8	7	South Dakota	0	0	0
Georgia	1	2	7	Tennessee	6	5	9
Idaho	0	0	0	Texas	8	10	9
Illinois	39	45	56	Utah	0	0	0
Indiana	3	7	9	Vermont	2	4	4
Iowa	2	5	3	Virginia	5	5	8
Kansas	1	9	4	Washington	0	0	0
Kentucky	4	9	4	West Virginia	0	1	0
Louisiana	4	3	6	Wisconsin	1	2	4
Maine	3	6	16	Wyoming	0	0	0
Maryland	17	16	17	Dist. of Col	12	23	33
Michigan	15	13	18				
Minnesota	2	4	4	*Foreign:*			
Mississippi	0	0	1	Canada	2	3	7
Missouri	40	41	39	Puerto Rico	2	4	3
Montana	0	0	0	England	0	1	1
Nebraska	4	3	0	Germany	0	0	1
Nevada	0	0	0	Portugal	0	0	1
New Hampshire	12	10	41	Cuba	1	1	3
New Jersey	56	80	64	Honolulu	1	0	0
New York	209	220	300	Brazil	1	0	0
New Mexico	0	0	0				
North Carolina	0	2	5	Totals	671	744	879

sorts, among them Newport and Narragansett Pier. Others not so well known, however, are very popular for Massachusetts and Connecticut motorists. So by a further process of deduction by taking 25 per cent. of Connecticut visitors, giving 6,250, and allowing 3,750 from Massachusetts and Connecticut regular registrations one gets 10,000, not a very extraordinary number. The state has some 14,000 registrations, so it is quite a motor section. All non-residents are merged with the regular registrations. From these figures one gets the following statistics:

New England Summer Figures

	STATE REGISTRATIONS.	VISITING CARS.
Maine	14,000	14,400
New Hampshire	9,900	31,300
Vermont	8,000	20,000
Massachusetts	60,000	44,880
Rhode Island	14,000	10,000
Connecticut	23,500	25,000
Totals	129,400	145,580

Now if 50 per cent. of the visiting cars are dropped as being machines which have duplicated by touring various states, or comprise also New England cars, it leaves a total of 72,790. And so, adding this latter figure to the state registrations, it gives the 202,190 cars touring in New England. And by multiplying each car by three one gets 606,570 motorists on the roads this summer.

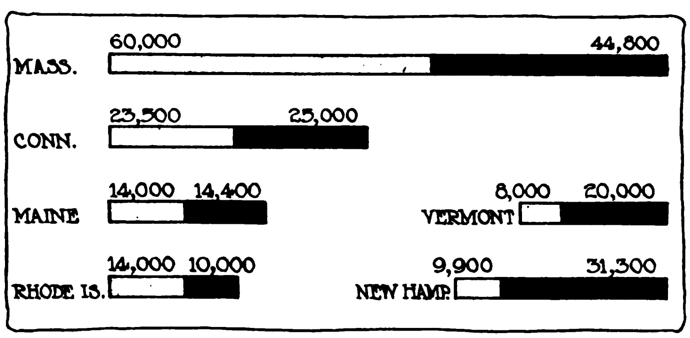
Here are the recapitulated figures:

Cars on the road, resident, daily	129,400
Cars on the road, non-resident, 60 days	72,790
Daily expenditure, resident	$129,400
Total expenditure, resident, 60 days	$7,764,000
Total expenditure, non-resident, 10-day average	$727,900
Total cars on road for summer	201,190
Total expenditure, all cars, all summer	$8,491,900
Total motorists touring, all cars, all summer	606,570

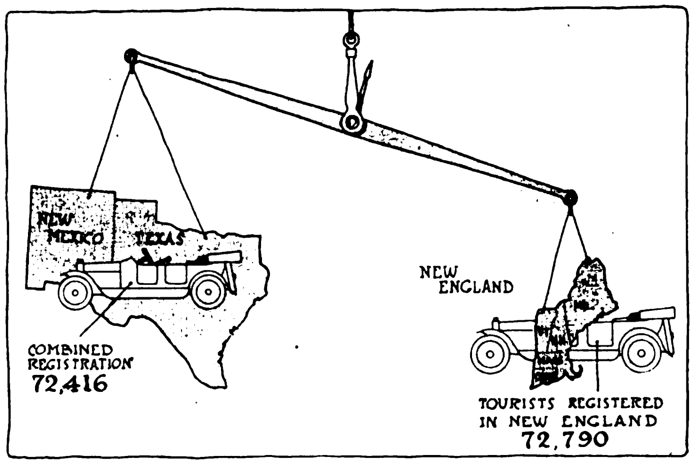
As New Hampshire registers her non-residents from the place where they happen to be staying while in her state, and Massachusetts gives the home address of visitors it is through the registrations on the Bay State books that one gets an idea of the cosmopolitan character of the visitors to New England every summer. The figures show that in 1912 there were twenty-nine states represented on the regular non-resident list. There were five foreign countries represented. Last year the number had been increased to thirty-one with but four foreign countries. This year there are thirty-three states on the list, with six foreign countries. The non-residents in 1912 were 671; in 1913 they jumped to 744, and this year the figures show 879. They would have gone higher but for the new law. The foreign countries represented during the 3 years comprise Canada, Porto Rico, England, Germany, Portugal, Cuba, Honolulu and Brazil.

New York Sends Most Tourists

For purposes of comparison the various states have been grouped together somewhat geographically. They give some interesting tables for a 3 years' comparison. New York, as a state, individually leads all others every year, having about



The shaded portions indicate the car registration of the New England states, while the black sections represent the number of visiting cars during the past summer



Cars from other states visiting New England last summer totaled 72,790, or more than the combined registration of the two great states of Texas and New Mexico

30 per cent. or more of the total. The other two big states are Pennsylvania and New Jersey, they being even with eighty each a year ago, but the former gaining one this year and the latter losing sixteen, dropping into third place.

The first group chosen naturally is New England. Maine made a big gain of ten, New Hampshire, thirty-one, Rhode Island, fifteen, Vermont remaining the same and Connecticut dropping thirteen. So the total is 148, a gain of forty-three over last year.

New England Group

	1912	1913	1914
Maine	3	6	16
New Hampshire	12	10	41
Vermont	2	4	4
Rhode Island	42	42	57
Connecticut	43	43	30
Totals	102	105	148

The Atlantic Coast group also shows a gain. Alabama and Mississippi are added this year, the first time for the latter. The District of Columbia shows a gain of ten, which, with the gain of a few here and there, offsets the big drop of New Jersey, and so there is a total of 150, a gain of seven.

Atlantic Coast Group

	1912	1913	1914
New Jersey	56	80	64
Maryland	17	16	17
Florida	3	8	7
Virginia	5	5	8
Louisiana	4	3	6

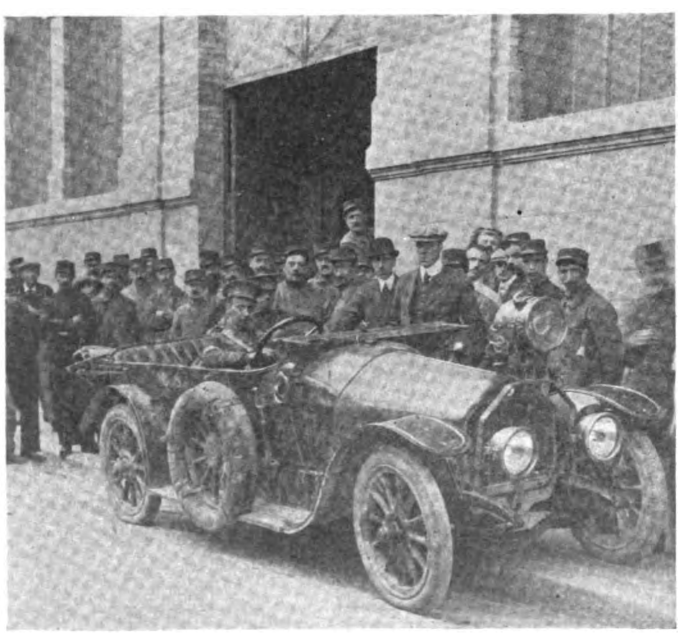
French Regulations Grow Stricter

Cars Confiscated if Rules Are Violated

By W. F. Bradley

Special Representative of THE AUTOMOBILE *with the Allied Armies in France.*

PARIS, Oct. 7—Non-military motorists are being held down tighter than ever. It may be an inconvenience to the motorist, but it is a remarkable testimony to the value of the automobile. Individual passes to use a car are given out by the military governor of Paris and must be renewed every week. These passes allow the holder to travel within an area approximately 6 miles around the city walls. If the car is taken beyond these limits it is confiscated. Special passes for a single journey to some town which must be stated are given out after personal examination of the applicant. If the town is in the war district, the application is rigorously refused. Even for other parts of France, not at all affected by the war, the pass will not be given unless it is shown that the applicant has real business to perform. These single journey passes must bear the photograph and signature of each person carried in the car. If these regulations are not observed the car is seized and the occupants returned under escort to their homes.



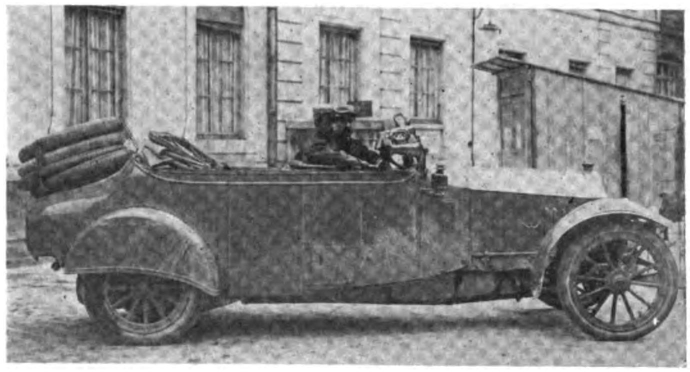
Lieutenant Director of Supplies leaving the Darracq factory for the front

Up to quite recently a number of cars have been going out to the Aisne battlefield to bring in wounded to the Red Cross hospitals. Although the drivers of these cars were registered and were always accompanied by an officer in the British army, orders have been given that they must be withdrawn. In future the wounded will be brought in by hospital trains to suburban stations and carried from there to the hospitals by car. R. N. Goode, manager of the Packard company in Paris, was one of the first to volunteer to bring in wounded from the front. In connection with the American Hospital, he has made a journey every day for a month to the battlefields, bringing in from one to three wounded officers and men on each occasion. In common with others he will have to stop this useful work.

A Packard has been the victim of an unusual adventure. A special pass having been obtained from the military governor of Paris, one English and three American journalists were taken out to the battlefield. The officers in the field refused to recognize the pass given by the Paris governor. The journalists were sent back by train and put under parole not to write anything for 9 days. The car and chauffeur were retained, the latter being ordered to instruct another man to drive it. After being put to rough usage for a week, the car was returned to Paris, but the chauffeur was kept under military observation for a week longer.

L. K. Clarke, one of the demonstrators attached to the Paris Packard branch, also broke through the lines with a body of journalists. The newspaper men were sent back and the car was seized. Mr. Clarke volunteered to serve with the English staff as driver of the car. His offer was accepted, and for a time he remained near the firing line, dressed in the British uniform, carrying English officers from point to point on his American car.

The stringency displayed towards motorists appears to arise from a fear of spies. A car is the most valuable adjunct a spy can possess. Only a few days ago a car entered Versailles carrying German spies disguised as British officers. Another party drove to the dock at Boulogne and were about to step on the boat for England when a slight mistake in their papers led to their arrest. In the districts where fighting is in progress it is absolutely forbidden for a civilian to take a car. In other parts of France the use of cars by civilians is cut down to the lowest possible numbers. In this way it is believed that a more rigid control can be kept on motorists and that spying and the spread of information can be arrested. People who have a need to travel and who cannot conveniently make use of the railroad are annoyed at the restrictions under which they are placed. They cannot protest effectively, for the military authorities will not admit discussion and newspapers will not publish their complaints.



Mercedes 60-horsepower armored car captured from the Germans and now used by French headquarters staff

Big Tire Business Expected After War

Goodrich Foreign Manager Thinks American Makers Should Reap Harvest

PARIS, Oct. 7—How the war has affected American tire interests in Europe was related to the Paris correspondent of THE AUTOMOBILE by Arthur Lumsden, general manager of the French and English auxiliaries of the Goodrich Tire Co.

"Our men had been paid as usual at noon on the Saturday France mobilized her army. At 4 30 o'clock the notices were issued putting the nation on a war basis. As our pay list is made up on Wednesday evening, arrangements were made for the cashier to be at the office on Sunday morning at 5 o'clock, in order that the men who were going to the front could collect their arrears of wages. In this way every man who left our works to go on active service went away fully paid.

"On Monday morning I was curious to see what the conditions would be at the factory. We found we had eighty men who were not eligible for active service. These men included most of those engaged in the band tire department. According to a previous arrangement with the French government, this department went under military control automatically as soon as war was declared, and we were put under an obligation to produce certain quantities of tires for army trucks." (This arrangement, it should be explained, is a part of the French army subsidy scheme. A couple of years ago Goodrich tires were admitted as part of the equipment of army subsidy trucks. Only the fact that the Goodrich company actually manufactures in France and has on its French board of directors men who have military responsibilities under the French law enabled this arrangement to be made.)

"London and Paris were violently panicky as soon as war broke out. The leading French tire firm, doing an immense business in England, called in all its stocks and refused to do business on anything but strictly cash terms. This move was followed immediately by the leading English firm. Deal-

Electric Vehicle Convention Opens—Over 400 Delegates Gather in Animated Session

Attendance of 500 Expected—Passenger Car, Truck, Battery, Parts and Accessory Makers Represented as Well as Central Station Interests

Interesting Papers Provoke Lively Discussion—More Activity in Building Business Urged

PHILADELPHIA, PA., Oct. 19—The fifth annual convention of the Electric Vehicle Association of America opened in this city today its 3-day session for the discussion of topics pertinent to the use of passenger and commercial electric vehicles.

By noon over 300 delegates had registered and it is expected that 500 will be in attendance before the convention closes. Those present represent the passenger and commercial vehicle departments of the industry, together with battery makers and other builders of component parts, such as motors, tires, frames and chassis necessaries. Over one-half the delegates are from central station interests, that is concerns in many cities manufacturing electric current for varied purposes.

More Activity Is Needed

The general sentiment among the delegates is that the electric vehicle industry has not progressed as it should and that more activity is necessary.

James H. McGraw, a New York publisher, read a very analytic paper, in which he endeavored to explain why the industry has not progressed as the conditions of the time warranted. Mr. McGraw regards the present condition of the industry unsatisfactory for three reasons: First, the novel character of the business has been depended upon to carry the business to a point where exhaustion has set in. Second, those responsible for the administrative conduct of the business have done little in a constructive or creative way to open up new lines of business and have depended too much on the routine of subordinates. Third, the central stations have not co-operated to the extent they should have in pushing the industry.

While considering the industry in its present condition Mr. McGraw thinks that all these ills can be corrected without superhuman effort, by simply applying to them such reasoning as will develop adequate comparison with progress made in other lines of business, and by adapting principles which have been known to bring results.

Dr. Steinmetz Answered

J. Crawford Bartlett, of Philadelphia, read a brief paper answering a paper read some months ago by Dr. Steinmetz, the eminent electrician of the General Electric Co., and one who ranks highest in the world in many electrical matters. In his paper Dr. Steinmetz prophesied the $500 electric that will travel 20 miles on one battery charge and have a speed of 15 miles per hour. He predicted 1,000,000 of such vehicles within 10 years.

Mr. Crawford in replying said: "Dr. Steinmetz predicted an electric of 20-mile radius for $500, and not an electric of 60 or 70-mile radius. I can take care of Dr. Steinmetz's $500 car for $7.50 or $10 per month as he prophesied. We had that kind of a car 10 years ago, but who would buy it today? Before 1909 I drove to Atlantic City in a 1,200-pound electric car, but today the public wants heavier cars and now I ride in one weighing 3,200 pounds. The public today does not want your puny, weak, electric, but is demanding the swift, sturdy, comfortable car that will go 75 miles on one battery charge. The greatest setback the electric vehicle industry received was the low-priced small vehicle of 10 years ago."

To Suit the Public

George H. Kelly, of the Baker Motor Vehicle Co., agreed with Mr. Bartlett that the public today wants the big car and not the little one. The electric vehicle makers are going to give the public what it desires in a car, rather than following a missionary course of trying to convince the public that it should use the light-weight, short-radius vehicle.

The Committee on Garages and Rates created much discussion when its report was read. The report contained a map of the Lincoln Highway, extending from New York to San Francisco. The majority of the report consisted of the tabulation of mileage on the Lincoln Highway, the ostensible inference to be drawn from the report as presented being that it was to show the possibility or impossibility of touring by electric from Coast to Coast. No sooner had the report been presented than George H. Kelly moved that it be laid on the table because the manufacturers of electric vehicles advertised their passenger cars for city use and not for country use, and that while the report on the map proved interesting information they were all wrong so far as the spirit of the electric is concerned. In America there are 225 cities of over 25,000 population, and in these the electric vehicle manufacturer should hope to make his sales for several years to come, and to these centers the association through its Committee on Garages and Rates should endeavor to assist the industry.

Animated Discussion

Immediately the convention was divided into two factions, those favoring the electric as a vehicle possible for touring, and those representing the industry considering it more in its present form as a vehicle for city use. P. D. Wagoner, of the General Vehicle Co., in siding with Mr. Kelly, believes that the public will not generally adopt the electric for touring purposes through the country until the speeds of the vehicles are higher than at present, and until batteries are perfected so that they will carry an entire day or until they are perfected along other lines which will permit them to be recharged or boosted in as long a time as it takes to fill a gasoline tank in a gasoline touring car.

The entire convention was not, however, of this belief. Day Baker, of Boston, Mass., and Treasurer of the Association, is a staunch believer in electrics and does his country touring in a machine that he has used for 8 years. With it he regularly makes the trip from Boston to Providence, 46 miles in 3 hours, whereas the average gasoline car making the trip does it in 2 hours and 30 minutes.

Improvements Necessary

Additional realism was added to the possibilities of cross-country touring by two electrics which recently made the trip from Washington to Philadelphia, and averaged 12 miles per hour for the entire distance. They do not recommend that people go touring in the ordinary electric vehicle as built today, as trouble will surely be encountered. The batteries are of not sufficient capacity, and other improvements are necessary in the vehicle.

J. M. Skinner, of the Philadelphia Storage Battery Co., believes that it is possible to use electrics for touring throughout all of the eastern United States, and corroborated his belief by citing that he has frequently made the trip from Washington to Boston without difficulty, averaging 50 miles per charge.

With the present charging facilities, there are only fifty charging depots on the line of the Lincoln Highway between New York and San Francisco, and of this number there are only fourteen west of the Mississippi River. With the present distribution it would be impossible for the tourist to even get from New York to Chicago, as there is one jump of 123.2 miles in Pennsylvania between Chambersburg and Greensburg, where there is not a charging station. This is the longest gap between New York and the Mississippi. West of the Mississippi there are but three stations between the Mississippi and the Missouri at Council Bluffs. There is not a single station between Omaha and Cheyenne, and from the time you leave Salt Lake City you do not meet with another charging station until you reach Sacramento, Cal.

Electric Taxicabs

An interesting part of the report was the fact that there are 600 electric taxicabs, or were before the start of the war, in Berlin, Germany. To keep these taxicabs supplied in batteries there are two battery maintenance systems in the city, one with 700 batteries, and the other with 450, the batteries having 250 amperehour capacity. These maintenance companies charge the operators 3 cents per kilometer for battery service, including minor repairs to the car, but not including washing and garaging. The chauffeurs receive as their compensation 25 per cent. of the fare, plus all tips. The expense of washing the cab is 25 cents, and one-half of this charge is taken out of the percentage earned by the drivers.

Changing the Batteries

The changing of batteries is handled as follows: The drivers are required to report at the maintenance depots at specified hours for changes of batteries, this practice distributing the load and reducing the number of employees in the depots. When the cab reports for a fresh battery the odometer reading is taken, and collection is made of the chauffeur or driver for the previous charge. When it is noted that a certain minimum mileage cannot be secured from a charge the taxi is required to go to the shop for overhauling. At the charging station the workmen are paid a premium when the battery life exceeds 10,000 kilometers.

The following are some interesting facts in connection with these system:

Number of taxicabs in Berlin	600
Taxi speed maximum miles per hour	20
Taxi income average per mile	$0.16
Battery capacity, at 5-hr. discharge rate, A. H.	250
Number of cells in battery	40
Life of battery plates, positive, miles	9,375
Life of battery plates, negative, miles	18,750
Time of battery change at depot, minutes	2.5

The prevailing conception that there are few electric vehicles in use in the different cities of Europe was fairly well exploded by P. D. Wagoner, of the General Vehicle Co., who has recently spent considerable time in Europe, investigating different aspects of the industry. Nearly every city in Europe has its quota of electrics. Thus Berlin in addition to its taxicab equipment has twenty-four electrically driven pieces of fire apparatus, thirty electric water carts for sprinkling the city streets, which are effecting a saving of $400 per vehicle per year over the previous horse system, sixty-seven electrics in the mail delivery service, etc. In Munich there are twelve three-wheel electrics used in the postal service, and Leipsig has twenty electric postal vans.

That the Electric Vehicle Association of America is not idle in its efforts to bring the electric vehicle before the attention of the postal authorities in Washington was well demonstrated in the report of the Committee on Parcel Post Delivery which was delivered by J. H. McGraw, who is Chairman of the Committee. This committee has been in touch with the Postal Departments, and has prepared a booklet entitled "The Electric Vehicle in Parcel Post Service for Economy and Reliability." Special letters together with a copy of this booklet have been sent to the President and his Cabinet, and to all members of the Senate and House of Representatives, to the Collectors of Custom of the principal parts of the country, to the postmasters in all cities of 10,000 population or over in the United States and Canada, and to all Departments of the Government, including army, navy, civil service, etc. The campaign was extended to Canada by having the Canadian Electrical Assn. take up the propaganda and spread it throughout the country.

In Parcel Post Work

The committee has gone further in developing the parcel post business in favor of electrics, and has secured detailed analyses undertaken by the Post Office Department to determine the parcel traffic in each of fifty of the principal cities for specific periods. The combined figures for these fifty cities, which have a total population of over 25,000,000, show that nearly 11,000,000 parcels were mailed out from these fifty post offices during the interval of October 1 to October 15, 1913, and 3,500,000 parcels were received at these fifty post offices for delivery during the same period. The average weight per parcel was 1 pound 11 ounces and the average parcel charge 10 cents. The cost of delivery by automobile was 5 cents per parcel.

Stimulating the Progress of the Electric Vehicle Industry

Inclination To Be Satisfied with Easily Secured Business Must Be Checked

James H. McGraw

TWO features of the problem which stand out boldly are the wealth of possibilities for large development, and the abundant resources among those engaged in the business. Yet in spite of great possibilities there is evidence of sterility in the comparatively little progress made. I say comparative progress judiciously, because I am not unmindful of the great number of vehicles already in service; but in view of what can be done and will be done, this is only a very limited beginning.

Three Reasons of Failure

If, therefore, we may be permitted to regard the present situation as unsatisfactory what are the causes? Aside from the generally depressed condition of business throughout the country, my investigations indicate that there are three reasons for the slow growth:

First, the novel character of the business, which, while it has brought large installations in the commercial field and successfully launched the passenger car, has been depended upon to carry the business to a point where exhaustion has set in.

Second, those responsible for the administrative conduct of the business have done little in a constructive or creative way to open up new lines of endeavor in exploiting their product, and have depended too much upon the routine performance of subordinates.

Third, defective collaboration from central station companies furnishing energy supply has not been received to the extent to which it must be exerted.

Taking up the first cause, we have a condition analogous to that which previously existed in nearly every other field of commercial endeavor where the introduction of new methods or of improved equipment became a problem. And in no case has substantial progress been accomplished until the impediments of novelty have been ruthlessly brushed aside by the stern and irresistible necessities of commercial enterprise.

This is the case with the electric vehicle. It has hardly reached a transitory stage. It is not yet commercialized. We are still fondling it as a luxury, hesitating to put behind it that dynamic energy necessary to force it upon the public which does not know its value and which is waiting to be convinced that it must have it and use it in great numbers as an economic necessity.

Considering the second cause, it must be evident to every keen observer that the solution of most of the many difficult problems now left to the salesmen must be made by those justly responsible for administrative functions. The inclination to drift with the tide of things, and be satisfied with business that can be readily secured, without any effort to sift out and win by sheer merit the more difficult but more profitable undertakings, must be checked.

The present semblance of weakness must be entirely changed, and upon the administration must be laid the task of discovering, testing and establishing those methods of organization and management by which all business productive energies may be united, stimulated, guided and rewarded.

A Great Opportunity

It is as much within the province of companies selling electrical energy to supply it for moving freight and merchandise as for other power applications, illumination, or passenger transportation. Yet the project has never been taken up seriously enough by them to realize the significance of its comparative value with the load now sought in their routine channels. The fact remains, however, that a great opportunity is passing by, practically unseen, except for a limited attention which is insignificant in comparison with what the prospect demands.

It requires but little observation to discover that the field has enormous scope. Every pound of material of any kind within the range of our vision in cities, excepting alone the original virgin soil and natural growths, has been moved at one time or another in some form of vehicle over the city streets. Every building has been carted in on wheels. All the vast equipment we make use of in any way whatever has been transported. In addition there is the enormous quantity of transitory merchandise, constituting our commerce, as well as our consumed materials; the sum total of which transportation might, and probably some day will, be performed electrically.

Some conception of this city vehicle load may be gained by reference to the volume of our transported materials in other directions. The annual tonnage originating on railroads for the past 8 years has averaged 800,000,000 tons. An equal amount was transferred to connecting railroads, thereby making the total annual rail tonnage over 1,500,000,000. It would be fair to assume that at least one-third of this finally reached our principal cities and was carted there at least twice over a distance of only one mile. We have a minimum of 1,000,000,000 ton-miles per annum. If the public service electric companies secure this business as completely as they have secured city rail passenger transportation and illumination, and it is practically within their reach, their profit would be enormous because there would be no such permanent investment or expense as is required in the present fields of their activity.

It is generally conceded that the freight tonnage reaching cities is handled many times over, but assuming as above that it was simply handled once from the railway to business premises and afterwards to the consumer, the above 1,000,000,000 ton-miles at an average energy consumption of 5 kilowatt-hours per ton-mile, would at the 4 cent rate reach a total figure of $200,000,000 per year, or nearly the present gross income of the central stations.

Now to consider the third cause. It may be well acknowledged that the attitude of the majority of central station organizations is favorable towards the advancement of electric vehicle projects, and that at least a half dozen of the larger ones are conducting organized departments for the advancement of vehicle use. Furthermore, all of them have liberally contributed to the funds of the general advertising campaign which has done such effective educational work in the past few years. However, it is equally plain that the central station effort is not at all in keeping with the enormous vehicle load which stands practically at its doors.

Millions in It

I have indicated in what direction the salvation of the industry lies. **We need to show the central stations of the country the great market offered by electric vehicles when they come into their own, and to induce them to preach their use in season and out of season as they do the use of lamps, motors and heating devices. Freight loads are larger than passenger loads and possess greater diversity. If, therefore, it is profitable to transport human beings electrically, how much more so would it be to transport freight; and if central stations are eager for railway loads, they should be even more keen to secure electric vehicle loads. I think they only need to be shown.**

European Development of the Electric Vehicle Industry

Discounting the War, Present Outlook for the Electric Abroad Is Very Bright

By P. D. Wagoner

As early as 1836, an American called Davenport of Brandon, Vt., built a model electric locomotive which was exhibited in London in 1837. In 1839 Robert Davidson, Aberdeen, Scotland, constructed a crude road machine that would move two persons along a rough floor. In 1840 Uriah Clark built at Leicester, Eng., a small storage battery weighing 60 pounds. Sir William Grove constructed his celebrated gas battery in 1842, and Gaston Platé began his researches in 1859, perfecting his battery 15 years later. Camille Faure took out his patent for material for the pasted plate in 1881, and in the same year Rafford of France brought out what Hasluck calls the first electrically driven road vehicle, followed by one G. Trouve 6 months later. The Ayrton (English) electric tricycle appeared in 1882. The first practical American Electric was probably the one built by Fred M. Kimball of Boston in 1888, and the first successful commercial electric, usually credited to Riker, materialized in 1897.

Electric Vehicles in Europe in the Spring of 1914

Country	Passenger	Trucks	3-Wheelers	Postal Cars	Total
Germany	862	554	3	270	1,689
Holland	70	38	1	6	115
Denmark	2	21	..	5	28
Sweden	2	2	..	2	6
Austria-Hungary	132	117	1	15	265
Belgium	1	..	..	..	1
France	100	190	..	28	318
Russia	3	4	..	1	8
England	201	62	..	25	288
Switzerland	131	69	..	..	200
Roumania	..	..	..	1	1
Spain	12	..	..	1	13
Italy	60	173	..	5	238
Total	1,576	1,230	5	359	3,170

Rafford's electric (1881) was a tricycle driven by an electric motor of less than 1-8 horsepower, fed by twelve small Faure accumulator cells. The whole vehicle weighed 176 pounds. Ponchain's 6-passenger phaeton appeared in 1893 with a Dujardin battery weighing 1,100 pounds, over one-third as much as the entire vehicle. In 1896 Darracq exhibited at the Paris Salon du Cycle, a very interesting electric coupé.

There were developments in England and Germany about 1896 and the Jenatzy car and delivery car is mentioned in an English engineering paper in 1897. In 1899 Jenatzy won the kilometer record (mileage contest) in France with his torpedo shaped electric called "Jamais Contente." The De Dion Bouton people brought out a light electric in 1901, the accumulator consisting of forty-four cells of twenty-one plates and giving 200 ampere hours capacity.

The British Electromobile Co. developed an electric in 1902 and the Waverly Co., and the Vehicle Equipment Co. invaded England the following year with electric passenger cars. The Compagnie Francaise des Voitures Automobiles brought out a car early in 1900 which had forty-four cells of Faure-King accumulator, with a maximum speed of 11.1 miles per hour.

The gasoline-electric automobile carriage appeared in France as early as 1899 and in 1902 an alcohol-electric run by Krieger was entered in French tests. The car weighed 2,910 pounds, the forty-four cell battery 882 pounds, and the car had a speed of 9.32 miles per hour.

In 1898 there were contests between electrically propelled hackney carriages in France and electric cabs were relatively successful there from 1899 to 1902. The Opperman Co. (German) placed an electric van in the service of the London Post Office in 1901. American built commercial electrics were shipped abroad that year also.

Europe's Important Part

I mention the foregoing to illustrate that Europe had a very important part not only in the development of storage batteries, but of electric vehicles as well. But all this development practically stopped so far as the electric vehicle is concerned about 1903. The progress made from 1903 to 1909 appears to have been spasmodic.

I regret to say that I cannot tell you positively how many going concerns are manufacturing electric vehicles and batteries in Europe today, but the number of the former probably does not exceed eight or ten. There are a number of automobile manufacturers who build a few electrics in conjunction with their regular line.

There are today approximately 3,200 electric vehicles in the whole of Europe. Probably 25 per cent. of the electric passenger cars in England are of American manufacture and possibly 10 per cent. of those in France. The number of commercial electrics exported to Europe is to date almost negligible.

The number of electric trucks in Europe is very small. The development has been along highly specialized lines; taxicabs, municipal apparatus and postal vehicles predominating, with a few score buses, public utility and mine working vehicles scattered through various countries. Few of the passenger electrics compare with our luxurious cars and many of the mail wagons are of the frail light weight, inexpensive tricycle type. Electric vans for wholesale dry goods, grocery and general heavy delivery service are used to only a very small extent in England and parts of Germany and France, and fleets of from twenty-five to fifty 5-ton or even 2-ton trucks are unknown.

Cabs in Berlin

Motor cabs first made their appearance in Berlin in 1900. Early in 1914 there were 3,090 horse cabs, 1,946 petrol cabs and 386 electric cabs in use in the city of Berlin.

A very interesting phase of the taxicab situation in German cities is the demand made by the police authorities that for every motor cab placed in service, one if not two or more horse cabs must be retired. In Breslau and Bremen, two cities having an unduly large number of horse cabs, five and four horse cabs respectively are removed for each motor cab licensed.

In some cities no motor cabs are allowed to start operation beyond a certain predetermined number, with the result that some hack drivers in Berlin have sold their permits to motor cab operators for 2,000 marks (about $475). In Munich the motor cab operator must show 100 marks operating capital and pay 3,000 marks to displace a horse cab operator who has been in business five years.

The Allegemeine Berliner Droschken Gesellschaft operates 200 taxicabs. They have several charging stations and 400 batteries. The battery is placed under the driver's seat. Batteries are changed in about 2 minutes by means of hydraulic lift. When fully charged these electrics make from 50 to 60 miles and some of the cabs can be speeded up to 22 miles per hour. Other taxicab companies operate smaller fleets in Berlin and other German cities.

Higher Speed Made

Electric trucks and delivery vans have a higher rated speed in Germany than vehicles of the same capacity in this country. One-half and 1-ton vans often have a speed of from 15 to 18 miles and at more moderate speeds give as high as 62 miles per charge, while 5-ton vehicles at 7 1-2 to 9 miles per hour give from 37 to 44 miles per charge.

Bakers and dry goods firms are beginning to use the electric in Germany and a few electric vans have been placed in storage warehouse work. Electric water carts are very largely employed, about thirty being used in Berlin alone. These carts water about 49,000 square yards of pavement per day of 8 hours against 30,000 square yards for horse apparatus. The saving of the electrics over horses is about $400 per electric car per year.

The Berlin Fire Brigade was using twenty-four electrically driven vehicles in March of this year. Electric dust carts are extensively used in Hamburg and Altona. Electric tractors are attached to water carts, slop vans, snow carts, street sweepers, etc., in some German cities. The Great Berlin Tramways use several unique electric tower wagons or break-down cars. The tower is placed on a 3-ton chassis and is removable.

In Mail Service

Berlin has sixty-seven electric vehicles in mail service. Nineteen of these are of the tricycle type, 500 pounds capacity; thirteen of the same type are of 900 pounds capacity; the remaining thirty-five are four-wheel vehicles of 3,700 pounds capacity.

Munich has twelve light three-wheel vehicles in postal service and Leipsig twenty-six electric postal vans of 3,500 pounds capacity. The latter are used principally in parcels post service though some move mail in bulk.

On March 1, 1912, the Vienna postoffice approved an experimental electric for

To Develop South American Trade

Establishment of Dollar Exchange and Perfection of Our Selling Machinery Recommended by Latin-American Trade Committee—Financial Assistance Needed by South America

ACCORDING to the Latin-American Trade Committee appointed by the Hon. W. C. Redfield, Secretary of Commerce of the United States, the best methods to remedy the present disorganization of our trade with Latin-America and to place it on a permanently satisfactory basis are the following:

1—The establishment of a dollar exchange, *a*—By the ultimate creation of a discount market; *b*—Pending the establishment of such for the extension of credit by the banks, an establishment of reciprocal balances in the United States and in Latin-America for financing trade.

2—Perfection of our selling machinery, *a*—By furnishing additional support to commission houses already familiar with Latin-American business; *b*—By forming associations of merchants and manufacturers to be jointly represented in Latin-America; *c*—By obtaining information as to the possibilities of developing retail stores in large Latin-American cities.

Extracts from the report and recommendations of the committee fellow:

An Opportunity

"An opportunity is now afforded to place the trade of the United States with other American nations upon a firm foundation, supporting a more comprehensive structure which may be built as the situation again more nearly approaches normal.

"The Committee feels, however, that there is great danger that our merchants and manufacturers unfamiliar with Latin-American conditions may be induced by recent publicity to undertake ventures in that field which not only will be unremunerative but actually disastrous, and, in their ultimate result, make for a reaction of the very healthy and much to be desired interest in foreign trade now manifest throughout the United States, an interest which, if properly directed, should be of great permanent value.

"The trade of the principal South American countries with England, Germany and the United States is shown by the accompanying table.

Our Exports Concentrated

"Our export trade to South American countries particularly, and to a lesser degree the Central American States, is concentrated. It is estimated that 75 per cent. of our principal exports to South America are the products of large organizations. Our principal exports to the River Plate may be roughly stated to consist of agricultural machinery and allied products, steel products, oil products—kerosene, gasoline, etc.—and printing paper of various kinds. Our exports to Brazil, Chile and Peru are largely limited to steel and oil products, locomotives and electrical machinery. Our trade in cotton cloths, shoes, stockings wearing apparel, and miscellaneous goods, has not made up an important part of the total because of our unwillingness or inability to meet British and German competition.

Our Imports Increase

"Even before the war our export trade to all Latin-America, and notably South America, had begun to decrease on account of the prevailing financial stringency. Our imports, however, increased in value, and the trade balance adverse to the United States for the fiscal year 1913-14 greatly exceeded that of 1912-13, both for all Latin-America and for South America alone.

"Since August 1 of this year the countries in South America whose currency is not already on a gold basis have experienced a serious depreciation of their paper money.

"The export of copper, tin, nitrates, coffee and other products has been curtailed because of loss of the normal European markets. As indicative of financial conditions, bank holidays and moratoria were declared at the outbreak of hostilities which were extended in certain countries from 60 to 90 days. The effect has been damaging to American exporters as, under such circumstances, drafts due in August will not be liquidated until November or December. This means a large accumulation of draft indebtedness never contemplated by the shipper. Specie payments were suspended.

"Collections throughout South America, therefore, are difficult, orders are falling off, and after our exporters have completed their contracts for this year, there seems less prospect for new business unless steps are taken to relieve the situation.

"Since the balance of our trade with South America is heavily against the United States, there should be exchange facilities which would enable our exporters to obtain payment from balances created in New York in settlement for goods imported into this country from South America. Such balances, however, are not maintained in this country.

"The external debt of the South American Republics (Federal, State and Municipal), amounts approximately to $1,632,488,580. The bulk of those funds were borrowed from Great Britain. South America therefore invariably has payments to make in London.

Britain's Supremacy

"The greater part of South American banking business, moreover, is conducted by British owned institutions. These facts, together with the facilities offered by the London discount markets, have induced German and other European owned banks trading in South America to maintain London agencies. Sterling credits, therefore, have been the basis of South American trade.

"Our exports to, and imports from, Latin-America are shipped direct. They are, however, (almost exclusively in South American trade, and largely in Central American trade) paid for in sterling bills of exchange.

"United States exporters have, in the past, converted their dollars into sterling at the rate of the day, drawing against their South American customers at 90 days' sight, payable in 90 days' bills on London. Importers have accepted 90 days' sterling bills, which they have liquidate at the current rate of exchange.

"Thus, although the balance of the South American trade of the United States has been increasingly heavy against this country, we do not make settlement direct. We have been obliged, either by the shipment of gold or goods, to settle this adverse balance by remitting to England either gold or goods, to meet interest charges on the South American debt, and to pay for goods purchased in Europe by the South American countries.

Present Problems

"Production in the United States can be maintained if there be a sufficient market at home and abroad for American goods. Production in South America may continue but cannot be further developed unless financial assistance be obtained.

"At the present time steamships are available and sailing regularly from this country to the principal ports of Latin-America and from those ports to the United States. Many of these vessels are unable to obtain full cargoes. Although only a limited number are under the United States flag the above will clearly indicate to exporters, importers and manufacturers that they need not hold back from entering the field on this account.

"Before trade can resume its normal course, the exchange problem must be solved, either by the restoration of old, or by establishment of new, credit facilities.

New Credit Machinery

"Old methods may no longer be serviceable in the situation which will result from the readjustment following the war. It should now be possible indeed, in the mutual interest of the Latin-American Republics and ourselves, to create new credit machinery to perform the functions of the old, and which will at the same time rid us, at least partially, of a dependence upon the London credits and European financial markets which, though essential in the past, has proved to be seriously embarrassing.

"It has been increasingly the practice of European bankers to stipulate the use of European material in the projects which they financed. Latin-America is now turning to the United States for funds. This country is hardly in a position to undertake considerable investments at the present time, **but industries with an already considerable trade at stake may well consider the necessity of protecting that trade by obtaining for their customers some relief from the present stringency. Such investments, if judiciously made, would yield an ultimate fair return and meanwhile provide a market for American materials which cannot now be sold.**

A Security Market

"The question of creating a market for Latin-American securities in the United States, therefore, is highly important. The development of our trade with those countries is largely dependent on its satisfactory solution.

"Unless the restriction of commercial credits be remedied, however, we will not only be unable to extend our trade but we will lose a considerable portion of that which we already have.

"The present effort to secure co-operation of American bankers in massing a gold fund to satisfy our obligations abroad by promising to cause London exchange again to approach normal, will lessen to the American importer the expense of liquidating in London his South American indebtedness. It will nevertheless give effect to the old alienation of the selling power we should derive from purchases of South American products. Liquidation of our South American indebtedness in London will pay for British exports to Latin-America, at a time when American merchandise, intimidated by moratoria, remains congested on our docks. Our available money will serve Great Britain's effort to capture South American markets vacated, perforce by Germany.

"Whenever there is a great disturbance of the world's finances, American exporters and importers in South American trade are injured, because of their dependence on London. **This has happened four times in 25 years.**

"So long as South America must meet interest settlements in London by shipment of goods to the United States, under the old three-cornered system, our South American trade must, to a certain degree, depend upon London exchange.

Independence Needed

"But in view of the facts above mentioned, it has seemed to your Committee that the need for independence, emphasized by the present situation, should be recognized. We feel that an attempt should now be made to evolve some plan whereby we might take advantage of our large direct trade with Latin-America to make a market for bills drawn in dollars, and establish a direct exchange, not with the view to eliminating sterling credits now or later, but in order to provide an exchange channel which will supplement, offset or compete with London, and be available in an emergency when London exchange is disorganized.

Co-operative Exchange Proposed

"A plan for the establishment of a Merchants' 'Co-operative Exchange,' or clearing house for Latin-American trade, has been proposed. This, it has been suggested, would enable importers and exporters of goods to and from Latin-America to watch credits, balances to be remitted on definite settling dates.

"The Committee, however, after careful consideration, feels that the suggested "co-operative exchange" would not be practical, although a powerful banking group or large banking institution willing to assist in maintaining and developing our Latin-American trade might be able to secure and render mutually beneficial the organized co-operation of exporters and importers in matching credits.

'The Committee, however, believes that the extension of credits might be facilitated and some relief afforded, pending the establishment of the Federal Reserve Banks, if, in addition to permitting national banks, which have signified their intention to enter the Reserve Associations, to accept commercial paper, action be taken by the Federal Reserve Board to make immediately effective the rediscount provision of the new banking system, thus assuring early establishment of a discount market.

Extension of Trade

"The question of extending American commerce with Latin-America depends primarily, as does the problem of maintaining our trade, upon the establishment of commercial credits, upon our ability to finance Latin-American enterprise, purchase the products of its soil and industries and upon the perfection of our selling machinery.

"Your Committee feels, however, that merchants and manufacturers now contemplating an entry into the Latin-American field should be careful to avail themselves of the easily accessible information concerning these markets. It is suggested that they should, at the outset, remember that the cost of maintaining individual representatives would probably be too great for any one of them to bear themselves. It is therefore suggested that associations consisting of the smaller firms or corporations engaged in kindred lines of production might be formed, and that either one or more representatives should be sent to South America to look after the interests of such associations, thereby bringing the cost of representation within a reasonable limit."

Trade of Principal South American Countries With England, Germany and the United States

		England		Germany		United States	
Country	Year	Imports	Exports	Imports	Exports	Imports	Exports
Argentina	1913	$126,305,556	$116,154,937	$68,815,721	$55,888,788	$59,861,703	$22,096,385

Autumn Painting and Varnishing of the Car

Protecting the Surface During the Autumn and Winter Months a Matter of Economy

By M. C. Hillick

PAINTS and colors on the automobile wear in proportion to the measure of protection afforded them by the varnish. At this season of the year, after the brunt of the summer campaign is well over, the average car surface is in urgent need of the additional protection which a coat or two of varnish applied at this time or during the next few weeks, will afford.

Saving Repainting

A great many car owners have come to appreciate the importance of varnishing, and, if necessary, of both painting and varnishing, the car during the middle or late autumn. Sometimes a coat of color and a coat or two of varnish applied in the autumn will save a lot of thoroughgoing painting repairs which otherwise might be necessary a few months later. **It is of the utmost importance that the exceedingly sensitive and delicate color coats be kept amply protected by varnish.**

Even car owners, usually indifferent to the actual paint and varnish needs, have in these later years learned to respect the value of maintaining plenty of varnish protection on the automobile. These men, fortunately, have recognized, and are more and more recognizing, that not alone the color coats but the pigments united into a foundation for the support of these colors need the protection which only a strong body of varnish can give.

Autumn Finish Needed

It is due to them, and to the information which they are prepared to give their fellow car owners that a more general autumn painting and varnishing of the automobile is now regularly being done. It is all a very real matter of economy. The surface of varnish that has been, during the summer months, cleaned, renovated and polished, until it would fairly seem stripped of all its substance, has very little left with which to protect and give life to the color coats, and, incidentally, to the coats protecting them.

The cleaning and polishing materials now so extensively employed upon car surfaces have a decided erosive effect. This erosion systematically practiced for a few months will, upon examination, be found to leave a very thin film of varnish to protect the undercoats.

Some Polishes Injurious

A recent examination of a number of different makes of cars which for a period of from 4 to 5 months have been regularly cleaned with patent renovators and polishes discloses the fact that in all cases the varnish has been worn practically threadbare, and in some, the finish has virtually disappeared, leaving the delicate fabric of the color entirely exposed.

Continued examinations of this character would doubtless disclose at this time an amazing percentage of car surfaces with the finish worn until it is no longer capable of serving as a protector of the painting.

Revarnish Every 6 Months

It has been demonstrated over and over again within the past few years that maintaining a strong and ample body of varnish on the car represents the very highest economy.

It has also been proved by numerous tests conducted by automobile painters that the average finish on the car exposed to daily road service needs replenishing at the expiration of 4 or 5, and at the longest, 6 months. To carry the finish along beyond that time without at least a coat or two of varnish, as local needs and conditions may suggest is to trifle with a matter of expense running up close to, and often reaching, three figures.

When the finish is found to have been worn through to the color, with this color materially affected by contact with direct sunlight, the weather, city gases, and other deleterious substances, a fresh application of varnish will not suffice to restore the surface to its original condition. More thoroughgoing measures are needed.

It would be a good plan for every car owner, or everyone invested with authority, to keep it in condition to examine the finish on the car carefully, in order to know personally about what the requirements are at this season of the year. In the main, the ultimate decision as to what the finish precisely needs should be left with the painter. The list of requirements at this time of the year runs, usually, from a simple revarnishing with one coat of varnish to the application of two coats of varnish, one rubbing and one finishing, and from that to a coat of color and two coats of varnish, and finally to thorough repainting throughout. As a rule, however, this latter class of repairs can be deferred until spring by the application of color and a couple of coats of varnish.

Varnish Indispensable

Under no circumstances should the finish, when showing visible signs of wear and tear, be left to get through the winter without the additional protection afforded by at least one full coat of varnish. The cases where a coat of rubbing, and over this a coat of finishing is necessary are provided by surfaces which show a dry and parched condition with more or less fine checks traced here and there through the varnish. The surface showing this condition will first need rubbing down with water and pulverized pumice stone. This process will break down the worn and harsh texture of the finish, cut away the dirt specks, grease, and foreign substances, and in a general way, put the surface in a receptive shape for the varnish coats.

Touching Up Spots

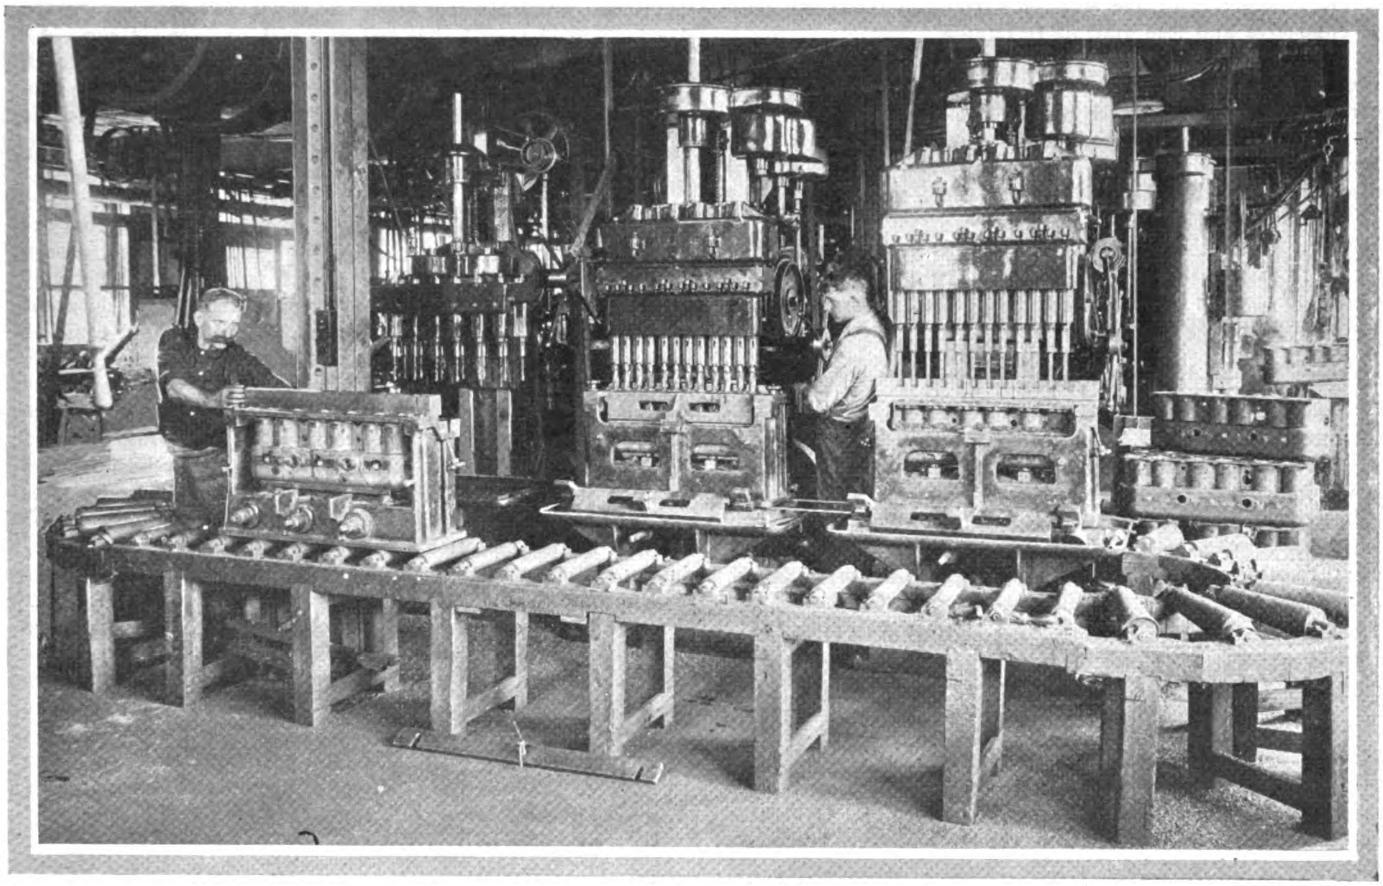
Following this rubbing process the surface should be carefully washed in clean water, and if marred or disfigured in any part, such places should be touched up with fresh color, matched to the existing field color. Making this match color is really one of the most important processes of all. A good eye for color, and experience in working in colors is required. Much depends upon touching up these bruised spots. This should be done with a small pencil brush, and the color should be confined exactly to the bruise. The expert colorist lays much store by this process, and he invariably mixes the color with enough varnish to cause the mixture to dry with a decided gloss, thus excluding the light from the pigment and causing it, when dry, to retain the same tone and shade displayed when mixed for application in the container.

Sealing Up the Checks

When the touch-up color has dried on the surface thoroughly, apply the coat of rubbing varnish. A considerable percentage of this coat will be taken in by the old finish, this absorption serving to seal up the fine checks and the weather beaten fabric of the old finish. Let this coat dry hard and firm, and then rub it down uniformly with water and pumice stone flour, after which wash and clean up thoroughly, and apply one coat of finishing varnish. The finish now presents its royal self once more, and is prepared, with a reasonable degree of care, to stand up strong and intact through the rigors, and the generally hard conditions, of winter service.

If the surface is in such shape that the rubbing coat of varnish is not necessary, a light rubbing with water and pumice stone will only be needed to make it fit to receive the finishing varnish. Touching the surface disfigurements, as above advised, with color will, of course, rank as one of the needed processes. In a general estimate, it may be said that the finish on very few cars which have been used throughout the past season is in a condition to undergo, without a fresh supply of varnish, the rigors of winter service.

Studebaker Machines Cylinders à la Merry-Go-Round and Saves Both Time and Labor



The extent to which the quantity production of high-grade motor car parts has been developed is often illustrated by specially-built machinery and equipment, but it is doubtful if a better illustration of this specialization can be found than the arrangement used by the Studebaker Corp. in its cylinder machining department. In drilling the stud holes, and in drilling and reaming the valve stem guide holes and push rod guide holes in a six-cylinder block casting only 15 minutes are consumed. There is no lost motion, though the blocks of cylinders are not light to handle by any means. One hundred blocks are handled a day by this crew of two men.

The three multiple-spindle machines are arranged in line so that the operator can manage all three at one time. The loader simply places the block of cylinders in the big jig and then pushes it around on the rollers to the first machine, the level of the roller conveyor being even with that of the table of the machine so that it is an easy matter to slide the casting in its jig onto the machine. Then the operator sets the drill in motion, drilling the thirteen stud holes at one time.

This finished, the operator pushes the jig over onto the table of the adjacent machine for drilling the valve stem and push rod guide holes, there being twelve of these. The casting finally progresses to the third machine where the last holes drilled are reamed out. The jig and casting are then shoved back onto the rollers, the jig removed and the casting picked up by a monorail conveyor which carries it to another machine for further work The heavy jig is then rolled around on the circular track to the loading point, when, after reloading, it goes again to the first drill.

There are several jigs so that there is no wait between loading and machining, the loader always having a new block casting ready for the first machine. This merry-go-round method saves the services of at least one more man, and perhaps two if the greater daily production which it makes possible is taken into account.

Thinks 12-Volt Electrical Systems Are More Efficient

The Automobile Engineers' Forum

Finds 6-Volt Types Satisfactory in Principle and Operation, but Considers 12-Volt Ultimate Favorite—Reader Points Out That All Standards Change—Opinions Differ on Economy of Using Oversize Tires

EDITOR THE AUTOMOBILE:—In our opinion, the 12-volt starting and lighting systems will ultimately be preferred by manufacturers of motor cars for the following reasons:

1—It is possible to use smaller wires and these are both less expensive and less difficult to handle.

2—Starting motors and lighting generators can be made lighter with the same efficiency or, if made to have the same weight, can be designed for higher efficiency.

3—If a single cell becomes ineffective because of a short circuit or broken jar, only 16 2-3 per cent. of the battery voltage is lost instead of 33 1-3 per cent., as would be the case with a 6-volt system.

4—The drop in voltage caused by the momentary heavy load of cranking the engine, does not result in as great a loss of efficiency in the motor nor is the drop as great in percentage in the individual cell.

Six-Volt Systems Are Good

We do not think that present-day 6-volt systems are in any way unsatisfactory either in principle or in operation, but feel that the 12-volt design is a part of the natural evolution toward improved efficiency.

We are convinced that just as strong and just as efficient lamps can be made with 12-volt filaments, once the manufacturers turn their attention to this problem.—WILLIAM S. GOULD, vice-president, Gould Storage Battery Co.

Takes Exception to Pneumatic Ideal Car Ideas

NEW YORK CITY—Editor THE AUTOMOBILE:—Willis A. Swan is interesting, without doubt an enthusiast, and that is in this dry age exceedingly refreshing. Unfortunately, automobiles are not built by enthusiasts, otherwise Mr. Swan would have by this time the pleasure of seeing his dream realized. I reread the epistle on two-stroke cycle engines on page 486 of THE AUTOMOBILE for September 10, written by a woman. At least, it speaks there contemptuously of "mere man." "Show me your friends, and I will tell you who you are." Since that epistle is of the broader scope I will answer that first with as much seriousness as is within my command.

The Changing Conditions

Alas, you dreamer, "the light of knowledge" is a very frail thing of but short existence. Where are the altars erected by those gone before us? Pilate, the governor of the conquered province of what we now call Palestine called out, "What is truth?" It is like knowledge, an intangible, everchanging phantom. As we are holding the knowledge of those of former days lightly; so will our day's knowledge be held in contempt some future day.

Even in mechanics we cannot establish a truth, for evermore this no one knows better than those who trod the unbeaten path, the "inventors." I hear Mr. Swan cry out that 2×2 makes 4 and forever will be, and that, therefore he has stated a truth which knows no time. My dear Mr. Swan, you have then stated that red was red, or green green. An accepted term of human intercourse is not Truth. A Truth is susceptible to interpretation and is therefore flexible. The same must be said about Knowledge; that, too, is like a river flowing. But see what you say:

Likes to Hear Motor

To quote: "The low volumetric efficiency and the fuel extravagance of the two-cycle are the results of poor design and poorer inventive ability." And later on: "Efficiency greater than that of the Diesel engine." H. A. B. does not seem to know that the Diesel engine is built in four-cycle as well as two-cycle; the statement therefore is not logical. When H. A. B. complains fuel extravagance then he or she is equally limping: What the comparison? The four-cycle engine? Are there not two-cycle engines showing as good an exhaust as four-cycle engines? that so, there would be no extravagance. Maybe, too much is expected from the two-cycle engine; everything has its limitations. To quote again: "Silence made absolute." There is no difficulty at all in producing a silent engine. Any good designer will take an order to eliminate what little noise there is left; but, dreamer that you are, you have not as yet experienced the pleasure of perceiving the music there lies in a motor which can be heard. But not alone that an experienced operator knows the need of an engine not silent, he learns to understand its language and in so doing the two become friends. Should the engine become distressed, its friend the operator will at once perceive the need of the helping hand and will apply himself in the right direction. But the grand finale: IT CAN BE DONE; IT HAS BEEN DONE.

Now, my dear Mr. Swan, do not conclude because I do not answer fully that what you have said is unanswerable. I have no wish to be rude, I have to keep in mind that space is limited and that the blue pencil of the editor is—well, is but a blue pencil.

Standards Ever Changing

Look backwards: Where are the standards of yesteryear? Do not be deceived because your horizon is small, that is no evidence that the world is no larger than you can perceive it.

All life is a never-ceasing battle; there are a great many standards in various fields of human endeavor that are this moment defending themselves against the onslaught of change or, as some call it, improvement. Our standards are but our momentary resting places; sitting-places, very necessary to keep our strength. They are after all but a link in the chain of events. Absolute standardization means abolishment of inventor and designer alike, and still you admire

H. A. B., who bids both to bestir themselves and produce?

Mr. Swan, you are happy to report that your Wheeling friends are able to produce alcohol so cheaply; but come now; think what would be the case if the U. S. government had standardized the methods of producing alcohol. What supreme master is to sit in judgment to say when the standard is reached?

Nevertheless, you will do the government a service if you will call attention to the misinformation they are handing out, whatever their intention. As to patent No. 692,218, I am sorry to say I am unable at this writing to consider it; I will hasten, however, to send for a copy of this patent, although the weight given is nothing worth mentioning, over 7 pounds per horsepower; when some engines of the first class weigh about 2 1-2 pounds per horsepower, and four-cycle engines, too.

Sees Difficulties in Operation

To quote you: "How simple. All we have to do is to run our present motor at a constant speed, at which it operates most economically." But, since you are unwilling to use gears and clutches, you will have to gear, pardon me, connect your motor to your axle, so that you run at about 3 miles per hour; many times, running between other vehicles, you must maintain that speed for long stretches; but would that not be rather slow? Connect at 20 miles per hour you say. Quite so, but then how are you going to slow down? Meanwhile you forget that your engine is running at about 2,000 revolutions per minute; to have an engine right on the axle under those conditions you will have to use rather small driving wheels, would you not, say of about the size of a spool of cotton thread? Maybe I am all wrong and those are little details you leave to the designers.

When saying that the internal gear is for the horsepower transmitted the most efficient of all; then I admit I have great difficulty in following you; do you measure efficiency in a gear by the surfaces engaged? The rolling friction is the least, you grant that? The rubbing friction the greater; now just study a common spur gear and you will find that if the teeth were but formed heart shape there would be an almost ideal rolling friction; now such gears are made for clocks and the like only, for the reason that at their bottoms they have no strength; the ordinary tooth of a gear is a compromise (as everything else in engineering if you but realized it). Now try an internal gear and you will find an amount of rubbing friction that makes that style useless for most purposes: For example, a certain chain hoist had such an internal gear, but the same people who made that hoist, instead of using but two gears as that hoist had, use now common spur gears and, if I remember correctly, five of them. Why, pray?

And air motors can be had at 5 pounds per horsepower! But an air motor cannot produce power. A gasoline engine is complete, but look at the air motor: You must have an air compressor to operate it that weighs how much? Five pounds per horsepower? That makes now 10 pounds per horsepower. You must have an engine to operate the air compressor that weighs 5 pounds per horsepower? That makes 15 pounds per horsepower. Things are getting rather heavy, are they not?

Carbureter Not Always Used

But, just think: Why not use the engine in the first place to drive the car? Ah, maybe I am a little dull. You are going to use that combination in lieu of gears. But, I am trembling with emotion! Common gears as now used are far more efficient than that, less costly and more reliable.

The three engines finally mentioned I confess I am well familiar with, but pardon me for differing with you; the Diesel engine is sure enough a type. By Hornsby you probably mean a type of engine built by the Hornsby-Akroyd people of England. I know of the Secor engine, but I have never heard anyone referring to that engine as a type. Nor are they the only people who do not use a carbureter.—B. H. BRITT.

Oversize Tires Economical for Both City and Country

NEW YORK CITY—Editor THE AUTOMOBILE:—In the majority of instances, the car manufacturer in selecting his tire equipment, merely takes into consideration the weight of the car when leaving his factory, regardless of what the actual weight of the car may be when it ultimately is delivered to the consumer and put into service by him.

For Overhead Work

What we particularly refer to is the added weight from extra equipment such as gas tanks, trunks, extra tires or even carrying more passengers than the intended capacity of the car. For this purpose tire manufacturers have constructed an oversize tire, which increases the outside diameter of the tire 1 inch and the cross-section diameter 1-2 inch—in this way making it possible to use a larger casing without necessitating any change in the wheel size. The enlarging of the tire takes care of the additional weight, preventing overloading of the tire equipment.

Oversize Increases Comfort

In addition to this, owing to the increased inner or tube surface of the casing, owing to the larger cross-section diameter of the tire, the car will consequently ride with considerably more resiliency, increasing the comfort of driving.

Oversize tires are constructed in such a way so as to properly fit the same rim as is built for the smaller tire, and if the tire is properly seated on the rim and kept properly inflated, there should be no side rolling movement.

It is just as advantageous to the city motorist to use oversize tires as to the country driver. Aside from the advantages of easy riding, this naturally will lessen the possibility of bruising the tires or injuring the carcass from riding over car rails and holes or unevenness in pavement, thereby greatly increasing the service obtained from the tires.

Although the initial expense of adopting the oversize casings may, at first, seem to be greater than would warrant the change, the fact of so many automobile owners adopting these larger size tires and the resultant additional service they get from them is, in itself, proof-evident that it must be to the owner's interest to make such a change.—AJAX-GRIEB RUBBER CO.

Thinks Use of Oversize Tires Is Seldom Necessary

NEW YORK CITY—Editor THE AUTOMOBILE:—We feel that the matter of oversize tires is often overdone.

The majority of the cars that are put on the market come out of the factory equipped with the minimum sized tire that the factory could equip the cars with for ordinary running purposes, but, as is generally the case, people use cars for touring over roads that put the tires to a rather severe test. Therefore, as a general rule, we would advocate oversized tires up to a casing of 5 inches cross-section, but when it comes to putting a 5 1-2-inch as an oversize on a 5-inch tire, we think the additional expense is out of proportion to the actual running service that they render unless it is a car that is being used under extremely hard circumstances and carrying a load of over 6,200 pounds.—COLUMB TYRES IMPORT CO.

The Rostrum

Suggests Hydraulic Clutch for Smooth Starting

EDITOR THE AUTOMOBILE:—Automobile operators use a low gear to get under way and high or direct for driving. This changing requires an undue amount of attention and labor which could be avoided.

The usual friction clutches do not allow slipping to any great extent such as would be necessary to get started on high gear ratio in the first place, but why be content with that?

Some 20 years ago a number of fluid clutches were designed to work in conjunction with electric motors on street cars. The present so-called series-parallel system of control device soon appeared and took its place.

Why not use fluid clutches in our automobiles? If this were done, the gearshift for starting purposes would be avoided and the cost of such a clutch is not prohibitive by any means.

A fluid clutch is not a positive hydraulic transmission device; whatever slipping takes place is lost power but the great convenience derived by its use makes up for it.

In simple form it is merely a rotary pump mounted upon the crankshaft of the engine, the rotor is keyed to the crankshaft and the housing to the shaft of the change-gear box. The pump is full of oil and the discharge is connected to the inlet with a valve in circuit. If this valve be wide open then the clutch is out and the oil will circulate continually. When the valve is entirely closed the oil, unable to leave the discharge, locks the rotor and the mechanism rotates as a whole. If the valve be partially open, the oil flow will find resistance at the valve and will in proportion to this resistance have a turning effort on the housing which is mounted upon the gearbox shaft—the greater the resistance to such oil flow, the greater the turning effort, that is, to speed up, one closes the valve and the car will get under way in proportion to the time used to close the valve. Simple, is it not?

Gearbox Also Required

It does *not* replace the gearbox although it permits the motor to run at maximum speed and the car at any speed, a mere creeping even. At full speed, like a planetary gear the mechanism moves almost as a unit, but not entirely so. There will be some leakage within the mechanism. At all other speeds the power represented in the difference of speed between car and motor is a total loss.

A fluid clutch heats, and that in proportion to the slippage. For this reason as great a radiating surface as possible is provided. It is likely that trucks would need to use a fan to keep the fluid clutch from overheating. Fluid clutches are filled with a heavy oil, and when hot this oil becomes as thin as water so that a definite notch in a quadrant cannot be used to set the control lever by. According to the degree of thickness or thinness of the oil the control lever requires to be set more open or more closed.

For very heavy work like gas-locomotives, which have great trouble to keep their clutches in order, a positive clutch must be employed in addition to the fluid clutch, so that the ultimate working strain will not be borne by the fluid clutch.

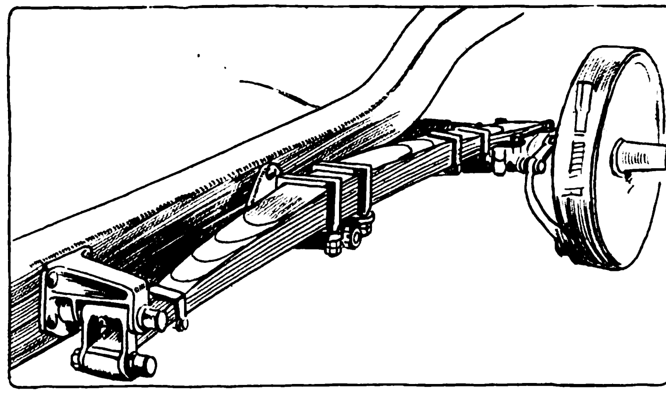


Fig. 1—Cantilever spring construction showing attachment to frame and axle

The life of a fluid clutch is much greater than a friction clutch, it will stand more abuse, since a car is brought up to speed more gradually by its use.

The fluid clutch offers a peculiar advantage in that it may be easily arranged to prevent the stalling of an engine, the clutch opening up automatically when engine drops below a given speed.

New York City. P. G. TISINER.

Wants to Install Cantilevers

Editor THE AUTOMOBILE:—I have been figuring on changing the rear springs on my car from platform to cantilever. If it is possible will you please show me by drawing how this is done, particularly how the spring is fastened to the rear axle, also whether or not it will be necessary to have radius rods.

New Albany, Ind. LEE E. SMITH.

—The cantilever may be used with or without radius rods. It is ordinarily fastened to the axle at the rear, pivoted at the center and shackled to the frame at the forward end, as shown in Fig. 1.

It is inadvisable to change your spring suspension as with your lack of knowledge of the subject you will decrease rather than increase the riding qualities of your car.

Six-Cylinder Two-Cycle Gives Smooth Torque

Editor THE AUTOMOBILE:—Since the gasoline motor does not begin to produce much turning effort of the crankshaft until 15 degrees after top dead center and produces its greatest turning effort at about 60 degrees, would not a six-cylinder two-stroke cycle so timed that when one cylinder was producing its greatest turning effort the next cylinder would fire, and at 15 degrees thereafter, would not this second explosion increase in turning effort as fast as the previous explosion increased?

2—If not, how many cylinders would be required?

3—To reduce vibration and weight, please show what, in your opinion is the best angle for a V-shaped, high-speed, six-cylinder two-stroke cycle motor not having crankcase compression, how to place balance weights on the crankshaft for this motor so that the best rotary balance is obtained, and how to eliminate the unbalanced centrifugal force at high speed, the shaft to be mounted on large ball bearings at each end.

Six-cylinder two-cycle all-in-line motors in flying boats run with very little vibration but I do not favor long crankshafts.

Tampa, Fla. L. C. HANNA.

—1—The turning effort of a six-cylinder two-cycle motor is very uniform as will be noted by the curve shown in Fig. 4. This curve was produced by combining six curves as shown in Fig. 3 which is the turning effort diagram for a certain single cylinder two-cycle motor. The crankshaft throws are set at 60 degrees. This turning effort curve is obtained from the curve of net piston pressures which is the upper one in Fig. 2.

2—No noticeable improvement in smoothness of turning effort would be obtained by the addition of more cylinders.

3—Probably the cylinders set at 90 degrees would give the best results. The method of balancing the cranks was described in the October 8 issue of THE AUTOMOBILE on page 663.

Valves Carbonize Very Quickly

Editor THE AUTOMOBILE:—I would be pleased to have your opinion on the following: A 1914 Ford car has been run about 4,000 miles, and carbon collects under the exhaust valves in from 50 to 200 miles after the valves are ground. I have had oversized pistons fitted, new valves, valve springs, carbureter, timer, plugs and coils, also master vibrator, fitted, and have used different oils and gasoline. The valves have been ground about fifteen times and after each grinding the car runs perfectly in every way, until the engine loses compression, when carbon will always be found packed under the exhaust valves. The exhaust does not smoke as though the engine was getting too much oil; there is plenty of play between the valve stems and push rods, and the timing is correct. The Ford magneto seems to give plenty of current, and the engine starts as easily on the magneto as on batteries.

Santa Rosa, Calif. W. E. V.

—There seem to be only one detail that you have overlooked and that is whether the spark is advanced as far as possible at all times. Even supposing that you drive with the spark lever advanced there is a possibility that the linkage has become loose so that the movement of the spark lever does not result in a corresponding advance of the timer.

Wants Racing Body for Ford

Editor THE AUTOMOBILE:—I would like to purchase a Ford chassis and fit a racing type of body to it. Will you please tell me where I can obtain such a body and what changes would have to be made in the chassis?

Grottoes, Va. DR. R. O. CONADA.

—The body can be obtained at a reasonable figure at any body makers. Probably $100 would cover the cost of fitting two bucket seats, gasoline and oil tanks, and painting.

Below are a few companies that are listed in the *Automobile Trade Directory* that might do this work for you:

Baily & Co., Lancaster, Pa.; Budd Mfg. Co., Philadelphia, Pa.; Collins Vehicle Co., St. Louis, Mo.; Schnabel & Sons, Pittsburgh, Pa.

The changes that you will make in the chassis depend on whether you desire a fast car or not. As far as the new body is concerned all that will be necessary is to lower the steering wheel and remove one leaf from the rear spring. If you desire an increase in speed, see the Rostrum for August 27, 1914, page 406.

Information on Most Powerful Engines

Editor THE AUTOMOBILE:—1—What cars made in America have the largest and most powerful engines?

2—What cars made in Europe have the largest and most powerful engines?

3—What cars made in America have the longest wheelbase?

4—What cars made in Europe have the longest wheelbase?

5—What cars are the longest including length of frame and wheelbase?

6—Will you supply me with the addresses of the Peerless and Marmon companies?

7—Can you inform me if the Thomas Co. is still making cars?

8—Who represents the French Berliet and the Itala cars in this country?

Ashland, Va. R. B. DEVINE.

—1—Below is a list of cars with more than 500 inches piston displacement:

Make	Cylinders	Cubic Inches	Bore and Stroke
Austin	6	667.9	4½ by 7
Chadwick	6	721.	5 by 6
Crane	6	563.7	4¼ by 6¼
Klinekar	6	503.8	4.32 by 5¾
Locomobile	6	524.8	4½ by 5½
Marmon	6	577.5	4½ by 6
Mitchell	6	595.8	4¼ by 7
Moyer	6	577.1	4½ by 5
Peerless	6	577.5	4½ by 6
Pierce	6	529.8	4½ by 5.3
Pierce	6	824.8	5 by 7
Simplex	4	590.	5⅜ by 6½
Winton	6	529.8	4½ by 5½

2—Cars in Europe with more than 10,000 cubic centimeters piston displacement are:

Make	Cylinders	Cu. Cen.	H.P.	Bore and Stroke
Benz	4	10,080	100	130 by 190
Cottin-Desgouttes	4	10,618	60	130 by 200
Isotta-Fraschini	4	10,618	100	130 by 200
Itala	6	10,634	60	127 by 140
Itala	6	12,912	75	140 by 140
Opel	4	12,978	80	130 by 165
Opel	4	15,216	100	140 by 165

3 and 4—The Simplex has a wheelbase of 12 feet while the Pierce-Arrow measures 11 feet 8 inches. Foreign cars with wheelbases of over 12 feet are: Berliet, 12 feet 6 inches; Delauney-Belleville, 12 feet; Metallurgique, 12 feet; Opel, 12 feet 4 inches; Pipe, 12 feet 2 3-4 inches; Renault, 12 feet 3 1-4 inches.

5—Cars, over sixteen feet in length over all are:

Daimler	16.8	De Dion Bouton	16.2½
Hotchkiss	16.2	Mercedes	16.3¼
Napier	16.	Opel	17.
Pierce	16.5	Rolls Royce	16.
Simplex	16.3	Spyker	16.4
Unic	16.2	Wolseley	16.6

6—The Peerless Motor Car Co. is located at Quincy Ave. and S. E. Ninety-third street, Cleveland, O. The Nordyke

and Marmon Co., at 1101 West Morris street, Indianapolis, Ind.

7—The Thomas Company is still making cars at the same factory, at Buffalo, N. Y.

8—The Berliet is no longer imported. Itala cars can be obtained from the Itala Import Co., Broadway and Fifty-seventh street, New York City.

Information on Acetylene Welding

Editor THE AUTOMOBILE:—Kindly inform me where I can get some information on acetylene welding? I am a blacksmith and would like to carry it along as a side line.

Is there a book published on the subject and where can I buy the necessary tools or apparatus?

Lawrence, Mass. CARL CASSE.

—A book which will probably suit your purpose is Welding, Theory, Practice and Tests, by Richard N. Hart, the McGraw-Hill Book Co., 239 West Thirty-ninth street, New York City.

Below are a few of the concerns, taken from the *Automobile Trade Directory,* that make welding apparatus: Cox Brass Mfg. Co., Albany, N. Y.; Dyer Apparatus Co., 39 Piedmont street, Boston, Mass.; Monarch Mfg. Co., 523 Stillwater avenue, Dayton, O.; Prest-O-Lite Co., 1400 Speedway, Indianapolis, Ind.

Stripping Down a Hupp 20

Editor THE AUTOMOBILE:—As I have just put my Hupmobile 20 machine up for the season and intend to strip it down to a raceabout when I get the time, I would like to have you suggest just how to go about it.

2—I would like to know how to get more power as I have had to throw it into low on nine out of ten hills that I have come in contact with this season.

3—How could I make a tire carrier for the rear end?

Springfield, Mass. F. C. S.

—1—The Hupmobile chassis is so short that it is difficult to place a good-looking raceabout body on it unless you go to the expense of lengthening the frame. However, the appearance of the body may be improved by moving the seats about 4 inches nearer the dash and fitting a round gasoline tank. There will still be enough leg room and the rear end of the body will look longer. If you have one of the early models which are equipped with bucket seats and gasoline tank in the rear, it is hard to see how you can improve on this design either as regards weight or appearance. But if you have one of the later fore-door designs you can replace this body with bucket seats. If possible, it would be best to get one of the old Hupmobile bodies of this type. Otherwise we advise you to have a suitable body built at the nearest body makers.

2—If your car is developing less power this year than heretofore it is very evident that something is wrong. Test the compression and grind any valves that require it. Then adjust the clearance between the valve stems and push rods. If there is not sufficient space to insert a calling card between each valve stem and push rod when the cam is out of contact, then the end of the stem must be filed if your motor is an early type or if a later one the push rods may be adjusted. Adjust the carbureter carefully and examine the ignition system. See that all the brushes in the magneto make good contact, that the breaker points have a gap of 1-64 inch when separated and that the magneto is correctly timed. Push the car over the floor and if it runs hard look for dragging brakes or excessive friction in other parts. Make sure that the clutch is not slipping. If it is, on opening the throttle suddenly the motor will be found to accelerate more rapidly than the car.

3—Any well-equipped garage can forge brackets for carrying the tires at the rear. Two brackets are required, made out of round bar stock and these are shaped as shown in Fig. 6. This figure shows a Hupmobile with unlengthened wheelbase, but with bucket seats placed on the floor and moved forward 4 inches, and a round gasoline tank fitted to the rear of the seats.

No Solvent for Graphite

Editor THE AUTOMOBILE:—Please give a formula for dissolving graphite.

2—In what direction is the strain of the torque arm on a Studebaker car in starting, stopping and reversing?

3—What is the percentage of increase of strain with an increase of speed?

King, La. C. D. JOHNSTON.

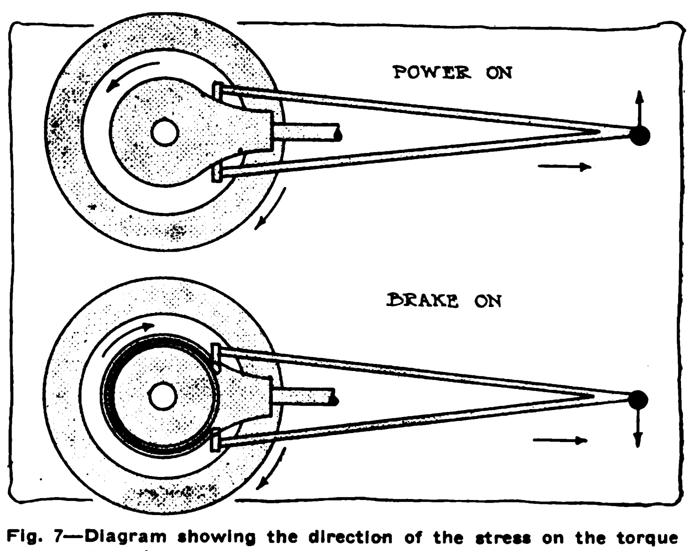

Fig. 7—Diagram showing the direction of the stress on the torque arm when the brake is applied and when the power is put on

—1—There is no substance that will dissolve graphite. Graphite is one form of pure carbon. There is a popular impression that many of the carbon removers are capable of dissolving carbon but this is not so. The compounds merely dissolves the oil holding the carbon to the walls of the combustion chamber.

2—As is shown by the arrows in Fig. 7, the stress on the torque arm when stopping is in a downward direction, the brake wheels tending to carry the axle housing and everything attached around with them, hence the downward pull on the torque arm.

In starting the stress is just the opposite, the driving pinion tending to rotate around the crown gear and carry the housing and everything attached with it.

Reversing produces a stress in the same direction as braking, the pinion tending to rotate the housing and the torque arm, downwardly.

3—The percentage increase in strain with increase of speed can not be stated without knowing the power that it takes to drive the car at different speeds.

Seven-Inch Tires Operate at Low Pressure

Editor THE AUTOMOBILE:—We have read with interest the paragraph headed Large Mileage from 7-inch Tires on page 558 of THE AUTOMOBILE dated September 17, based on information communicated to you by Mr. Thomas L. Robinson. We think this gentleman must have been mistaken with regard to the pressure at which our 7-inch cord tires are run. Contrary to the very general opinion that the larger tires call for higher pressures the reverse actually holds good, as you will see from the pressure table below:

Load per Wheel,	Minimum Inflation Pressure in Pounds per Square Inch							Load per Wheel,
Cwts.	3" 75 and 80 m/m Light Car	3½" 90 m/m Light Car	3½" 90 m/m	4" 105 m/m	5" 120 m/m	6" 135 m/m	7" 175 m/m	Lbs.
2½	35	30	..	..	..	..	..	280
3	40	36	30	..	..	..	..	336
3½	45	42	35	..	..	..	..	392
4	50	48	40	32	..	..	..	448
4½	..	54	45	36	..	..	..	504
5	..	60	50	40	..	..	..	560
5½	..	66	55	44	..	..	..	616
6	..	72	60	48	42	..	..	672
7	..	..	70	56	49	35	..	784
8	..	..	80	64	56	40	..	896
9	..	..	..	72	63	45	..	1008
10	..	..	..	..	70	50	40	1120
11	..	..	..	..	77	55	44	1232
12	..	..	..	..	84	60	48	1344
13	..	..	..	..	91	65	52	1456
14	..	..	..	..	98	70	56	1568
15	..	..	..	..	105	75	60	1680
16	..	..	..	..	..	80	64	1792
17	..	..	..	..	..	85	68	1904
18	..	..	..	..	..	90	72	2016
19	..	..	..	..	..	95	76	2128
20	..	..	..	..	..	100	80	2240
22	..	..	..	..	..	..	88	2464
24	..	..	..	..	..	..	96	2688
26	..	..	..	..	..	..	104	2912

The average load on the back axle of cars such as the Rolls Royce, Sheffield Simplex and Daimler referred to in Mr. Robinson's letter is 24 hundredweight. To carry this load a 7-inch Palmer tire only has to be inflated to a pressure of 48 pounds per square inch, a very different thing to the 110 and 125 pounds mentioned in your paragraph. The front axle weight is seldom more than 1 ton for which a pressure of 40 pounds per square inch is sufficient. Any of the smaller six-cylinder English cars fitted with open touring bodies are run with our 7-inch tires inflated to pressures of 35 and 40 pounds respectively for front and rear tires.

The 7-inch Palmer Cord Tire is capable of dealing with loads up to 2,900 pounds per wheel and for this load they have to be inflated to a pressure of 104 pounds, but no touring car approaches anything like this weight and it is only on motor lorries or as we believe you call them, trucks, that such loads and pressures are usual, even then a total back axle load of 2,240 pounds calling for a pressure of 80 pounds per square inch is more general.

We have only recently become subscribers to your journal and we have already found in it much information of interesting value which is not to be found in the automotor journals on this side.

London. G. A. PARSONS, The Palmer Tire, Ltd.

Wiring Diagram of 1913 Studebaker

Editor THE AUTOMOBILE:—1—Please show in your columns the wiring diagram of the Studebaker-Wagner single unit starter generator used on the model 35 Studebaker car made in 1913.

2—The generator does not close the relay. After the relay has been closed by hand, the output is low, gradually building up to the right amount. All this happens at the same engine speed. Generally after the car has been driven a few miles with the generator working, the relay closes and opens as the car speed varies but sometimes it opens and stays open if not closed by hand.

The machine has been cleaned with sand paper and the brushes on the back end have been advanced, but this does not seem to help it.

Omaha, Neb. EVERETT M. ROGERS.

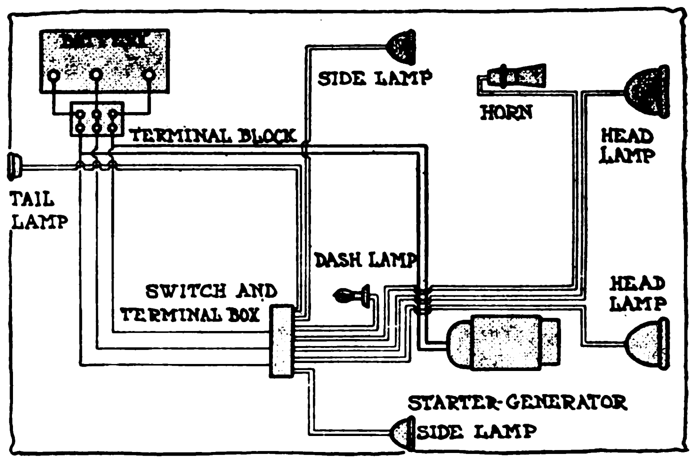

Fig. 8—Diagram of wiring of starting and lighting system used on 1913 Studebaker. Starter, generator and battery operate at 12 volts while 6-volt lamps are used. The wires from generator to battery are shown in black

—1—Fig. 8 shows a diagram of the wiring system used in 1913 Studebaker automobiles. It is a 12-volt system of the double wire type. Starting motor and lighting generator are combined in one unit. The wiring connections for the starting system are shown by the heavy lines and the other lines represent the lighting wires. Since the lamps and horn are designed for 6 volts a three-wire system is used to carry current from the battery to the terminal box from which these units are supplied. In other words, the difference in electrical pressure between the two outside wires is 12 volts but the difference between each outside wire and the central one is only 6 volts. The lamps and horn are connected to the junction box.

2—The mica insulating the commutator segments has probably worn faster than the metal in the segments, and particles of metal have bridged the gaps between the segments. The remedy is to cut these small particles of metal away with a knife but this is a job that should only be intrusted to an expert. You should take your car to a Studebaker service station.

The Engineering Digest

Latest German Omnibus Construction Follows London in Worm-Drive Type But Establishes Competing Model

LAST May the Berlin Elevated Railway Company placed its first motor omnibus feeder line in operation and the vehicles of this new enterprise distinguish themselves from other motor omnibuses in Berlin by quietness and other constructive advantages. Out of the 60 new omnibuses now in commission 20 are made by the NAG company (Neue Automobil-Gesellschaft) at Berlin-Oberschöneweide and in their construction the type of compound spurwheel and bevel gear drive in the rear axle which for the last 1 1-2 year has been found acceptable by the General Berlin Omnibus Company has been adhered to. The other 40 vehicles are made by the Daimler Motoren Gesellschaft at Berlin-Marienfelde and are largely based on the latest experiences made with Daimler omnibuses in London, having the gear changes operated by silent chains and the final drive by worm in the rear axle.

A previous motor omnibus feeder line system which was adopted by the Grosse Berliner Strassenbahn A. G. (Large Berlin Street Railway Company) did not prove financially successful, but it is believed that the conditions in the present case are far more favorable, partly because much useful experience with regard to the constructive requirements has been accumulated since and partly because a feeder system is much more urgently needed for the long-distance elevated railways than for the close network of surface street cars.

In the new NAG as well as in the German Daimler omnibuses it has been one of the main objects of the builders to avoid permanently all strident noises from gearbox, rear axle and motor, while the first cost of production, the wear and the maintenance expenses and other standard considerations for omnibuses are of course also kept in view throughout. The means adopted for these purposes, so far as design is concerned, will be made clear from the following descriptions and illustrations.

Construction of the NAG Omnibuses

The chassis of the NAG buses shows in the main standard arrangements apart from the rear axle drive. The frame reaches, pressed from 8 millimeter sheet steel, extend for almost their entire length at a height of 154 millimeters from the ground and at a uniform distance of 770 millimeters from each other; that is, without narrowing at the front. The steering angle is nevertheless sufficient, as the front wheels are so far apart as to track in the middle plane of the twin-tired rear wheels, and not with the inner rear wheels tires. Of the transverses one lies under the radiator, the next one between the clutch and the gearbox, so as to support the front end of the latter, the third and strongest one at about the middle between the axles, where it takes up the entire traction push. The fourth one comes near the front shackles of the rear springs and the fifth so far from the rear end of the reaches as to leave room for the convenient riveting of two brackets for the support of the boarding platform of the omnibus. These brackets are braced by diagonal struts, though this is not shown in the plan view, Fig. 2.

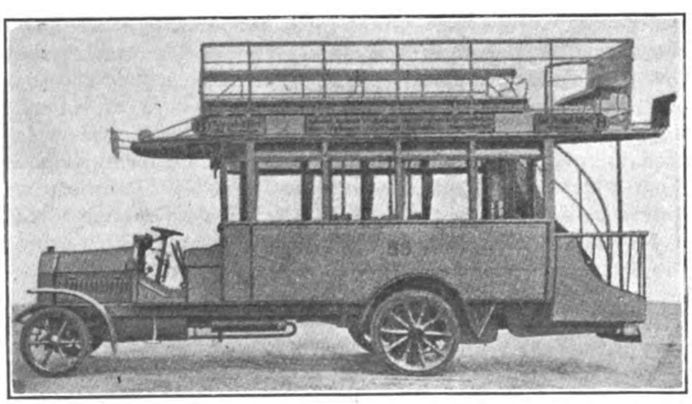

Fig. 1—New NAG omnibus, of which 20 are placed in commission in Berlin. A relatively cheap construction with danger spots carefully reinforced

Motor Very Conservative

The four-cylinder motor, with cylinders of 110 by 150 millimeter bore and stroke, develops 32 to 35 horsepowers at 900 revolutions per minute, and is of the T-type, the cylinders cast in pairs. It is supported in the frame by two transverse steel straps which are sufficiently flexible to protect the crankcasing against any bad effects from warping of the vehicle frame. Silence of valves is secured solely by suitable shaping of the cams and not by the usual boxing. The carbureter is placed between the two cylinder castings and draws its air through a pipe with intake around the exhaust manifold on the other side of the motor. The magneto and the centrifugal water pump are on the exhaust side on a shaft parallel with the camshafts and driven from the camshaft gear. Automatic oiling of the three crankshaft bearings is effected by means of a gear pump driven from the middle of the camshaft on the intake side by miter gear and a vertical shaft, as shown in Fig. 3. The oil is not driven to a level higher than that of the crankshaft and thence led by gravity to the bearings but is forced into a distributer tube along the wall of the casing and from this tube by short leads upward into the bearings; a longer branch tube takes a portion of the oil to a sight glass on the dash. The quantity of oil in the circulation is determined experimentally and is not subject to adjustment. Similarly the oil in the sump for cylinder lubrication by splash remains at an unchangeable level, so as to obviate smoky exhaust as much as possible by simple means.

Cone clutch, four-speed gearbox with direct drive on high gear and service brake at the rear and, finally, the usual driveshaft with universals at the ends transmit the power to the compound bevel and spurwheel gear on the rear axle which is the principal feature departing from standard design. The gear ratio between the driveshaft *a* and the rear wheel shaft *l* is here determined by the bevel gear proportion of 13 to 45 and the spurgear proportion of 21 to 41 giving a total ratio of about 1 to 6.75 on high gear, at which *a* revolves at the same speed as the motorshaft. The maximum vehicle speed at a motor speed of 900 revolutions is hereby limited to 21.6 kilometers per hour, a centrifugal governor on the camshaft limiting the motor speed by throttling the carbureter.

The rear axle consists in the main of three parts. The steel casting *f* in the middle is divided lengthwise horizontally

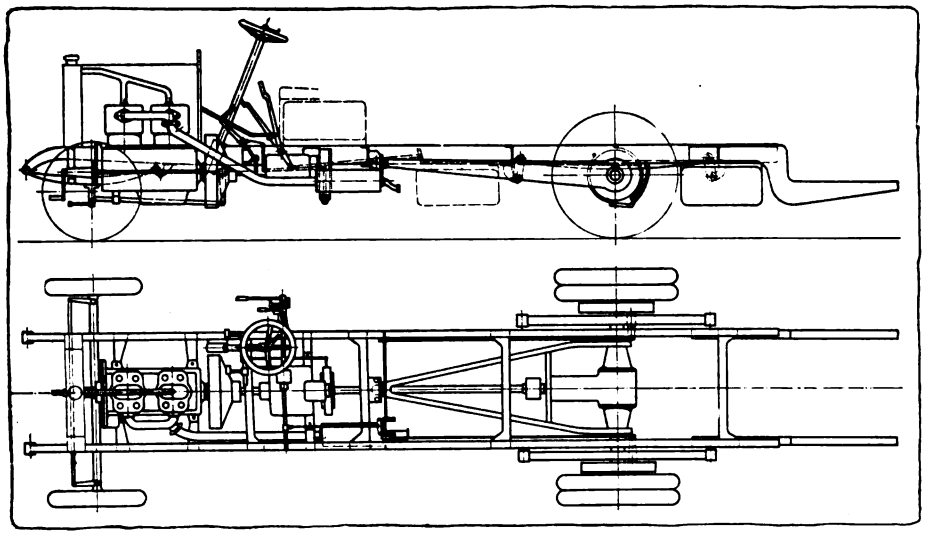

Fig. 2—Outline views of NAG omnibuses with T-type, low-speed motor and compound spur and bevel gear in rear axle

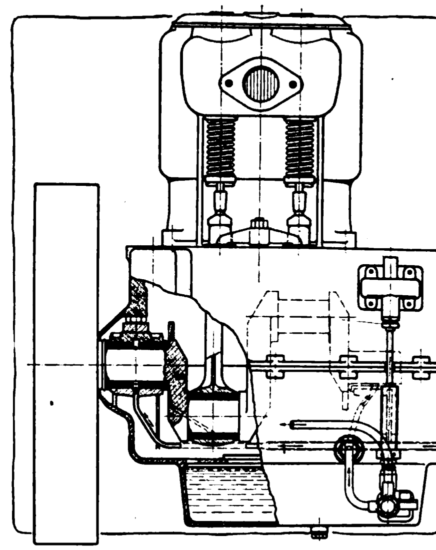

Fig. 3 A—Side view partly in section, showing oiling system, of NAG motor

and carries the transverse box g which is undivided and completely inclosed to the exterior and in which the short jackshaft h for the small spurwheel d runs in very stout ball bearings. The large bevel wheel c is mounted on the same shaft h, jaw-coupled to spurwheel d, but it is not mounted with a drive-fit and is therefore susceptible of such slight lateral displacement as has been found in practice to secure quiet running. The correct alignment of the spurwheel d is secured by the small end-thrust bearing on one side and the adjustment nut i on the other. The final spurwheel e is mounted on the housing k of the differential which runs on ball bearings in the axle and contains the usual cluster of bevel pinions mounted by means of bushings, and the hubs of the pair of pinions splined to the wheelshafts are especially long, the details of the whole construction being shown very plainly in the scale drawing, Fig. 4. The bevel gear driving-pinion b is made in one piece with shaft a and is carried very securely in the front portion of the casting f by means of three radial and one side-thrust ball bearings. The splines in the hubs of the side pinions of the differential and those upon the wheelshafts l are made very accurate, so that the shafts may be withdrawn easily after unscrewing the wheel caps m, in case of an exchange of driving-wheels.

The wheels are pressed upon steel hubs o, which are provided with the oilcups shown in dotted lines, and these revolve upon bushings between steel rings p and q. Ring p is screwed upon the axle and ring q is secured by nut r which is furthermore pinned to the axle end.

The customary triangular frame transmits the driving thrust and torque to the middle transverse of the vehicle frame without any intermediation of the vehicle springs and abuts with its front end against a steel ball; it follows therefore every small lateral movement of the rear axle which can occur when the rear springs are flexed unevenly. The reaches s of the triangular frame are secured by bolts to hubs t which are pressed upon the rear axle, and boxings carrying the rear springs are mounted upon the same members. The reverse torque arising from braking is also taken up in the axle construction without reaching the springs, the brakeshoe carriers u being secured to the axle by cones and

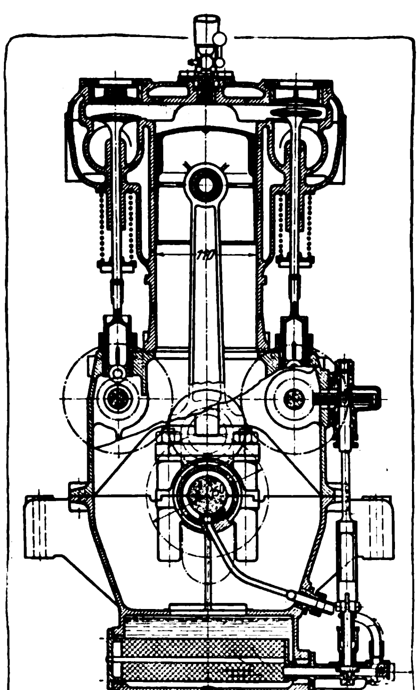

Fig. 3 B—Cross-section of NAG omnibus motor silenced by gentle cams, low speed and accurate gears

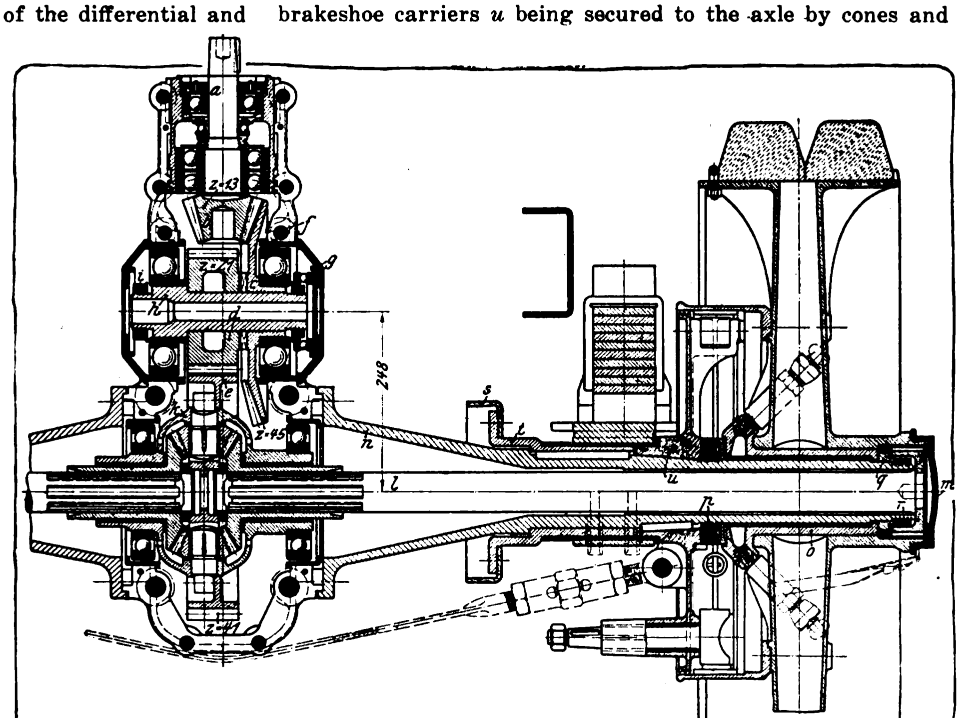

Fig. 4—Rear axle gear and drive of NAG omnibuses, involving many details intended to secure noiselessness and durability. Casing is divided horizontally, excepting middle portion g, which is undivided. Parallel wheel bearings

wedges; they are formed as disks which snugly close the face of the brake drums and the brace rod under the axle is secured to them.

By the construction described the driving system remains entirely unaffected by the load or turning movements of the vehicle, this being an urgent requirement where the question is of such weights as come into play in the case of omnibuses. The silence of the system is due in some measure to the gear reduction arrangement by which the bevel gear precedes the final spurwheel gear, rather than having the action of the latter incorporated in the gearbox, as it is an old experience that it is more difficult to quiet a spur gear than a bevel gear above certain circumferential speeds.

The objections to the system lie perhaps exclusively in the great weight of the rear axle gear which involves severe stresses on rough pavements and may come in conflict with regulations prescribing maximum axle loads.

Construction of the German Daimler Buses

As compared with previous types of Daimler buses the general arrangements of the chassis show the change that the gearbox has been moved further back and is supported separately from the gear-shifting shaft. The pressed-steel frame is relatively narrow and the front wheels track with the inner ones of the rear twin tires.

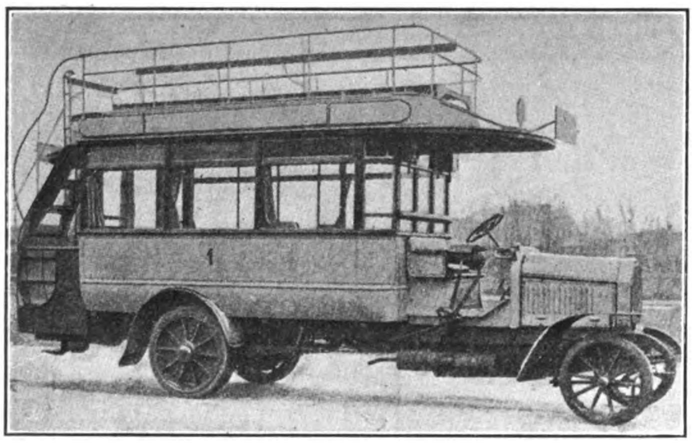

Fig. 5—German Daimler omnibus with worm drive and silent-chain gears; 40 placed in commission in Berlin

The motor is hung in the frame at three points, with the apex in the front transverse; the cylinders are cast in pairs, and the valves, in removable boxings in the cylinder heads, are operated from a single camshaft by rocker arms, the advantages in fuel economy being those generally obtained from this type. At the speed of 1,150 revolutions, which gives 43 horsepowers, the maximum, a mean piston pressure of 6.4 atmospheres is maintained, which is unusual. [Details and illustrations of the motor are here omitted, as it follows the well-known Daimler type closely.—Ed.]

The cone clutch differs from previous designs for omnibuses by eliminating end-thrust upon the motorshaft from the clutch spring whether the clutch is in or out. That this is the case when the clutch is in action is immediately apparent from Fig. 6 which shows the construction. When the clutch is released by pressure on pedal *d*, the toggle joint of levers *e* and *f* is flattened and, as *f* abuts in the ball bearing *h*, which is fixed, the other ball bearing *g* is shoved forward, and thereby the cone *b* is released from the flywheel, being at the same time braked by the resiliently mounted brake ring *i*. The axial pressures from clutch spring *a* are completely balanced between the bearing *h* and the spring cup *c*. As, further, no pressure can be transmitted backward to the pedal through the flattened toggle joint, the operation of the clutch does not become fatiguing.

The leather disk universals between clutch and gearbox, as

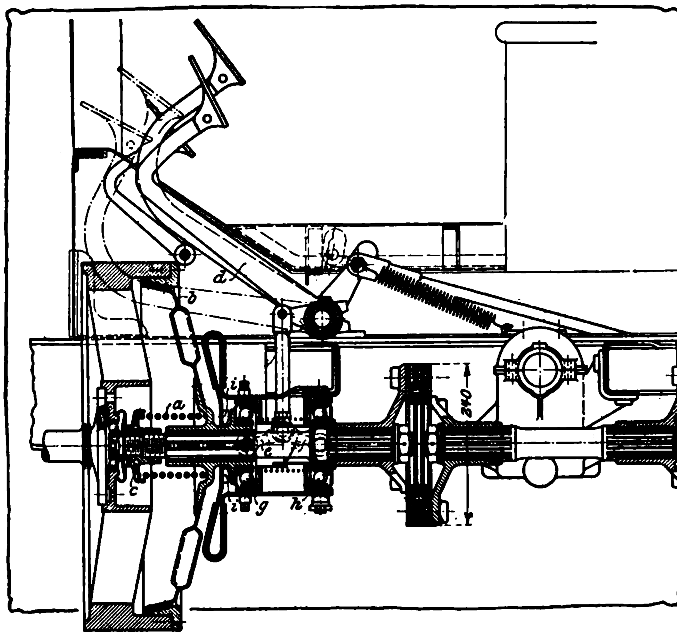

Fig. 6—Self-contained clutch with automatic brake and anti-fatigue toggle lever

well as between gearbox and rear axle, constitute an innovation in German practice. Each joint consists of three rings of sole leather separated by sheet steel disks and riveted together, and they are gasped from the opposite sides by three-armed spiders which are staggered with relation to each other; at least one of the spiders, whose hubs are splined to the shafts, is capable of longitudinal movement.

The change-gear, Fig. 7, differs from the British prototype by its larger dimensions. To obtain silent operation, the third speed, being that mostly employed, is direct, and the other gears are actuated by silent chains and non-slidable sprocket wheels.

From shaft *a* shaft *d* is constantly driven by the gear *bc*. Shaft *e* runs reversely with minimum speed when the spurwheels *f* and *g* are in mesh, and with the highest forward speed when the clutch wheel engaging its hub portion is shoved forward and couples the chain gear *hi* to shaft *e*. The second speed is obtained by coupling sprocket *m* to shaft *e* by means of clutch *k*, and the third speed by moving the same clutch forward, connecting shafts *a* and *e* directly. All engagements are protected against unintentional displacement by the well-known locking system for the shifting-rods.

The dimensions of the gearbox are necessarily large with the chain system, and intermediate bearings are therefore required for the shafts to avoid vibrations. For the same reason the casing is braced by horizontal transverses at two different levels. Underneath it a rounded pan protects the street from drippings.

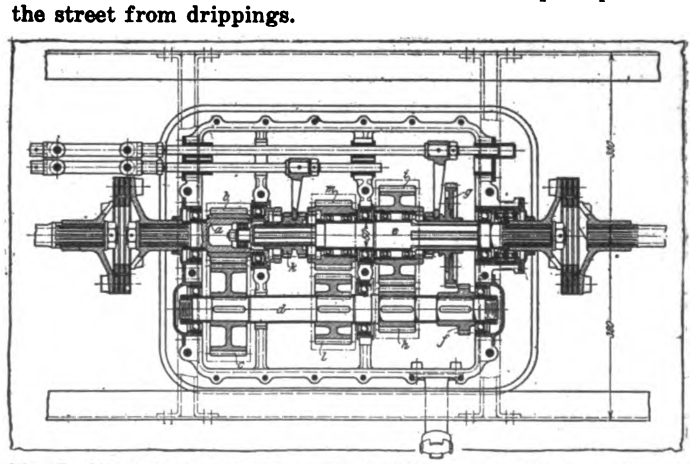

Fig. 7—Silent-chain gearbox with direct drive on third speed and leather universals

The rear axle design is shown in Fig. 8. Its most characteristic feature is of course the worm drive. The quintuple steel worm *a* is hardened and ground and drives a 32-teeth bronze wormwheel *b* mounted on the differential housing. The whole drive is so mounted in the cover *c* of the rear axle casing *d* that it can be removed easily in its entirety from above. The worm is as usual secured by an exceptionally strong double-acting end-thrust bearing at the end of the shaft, and the wormwheel is secured laterally by thrust bearings at the sides of the differential. The steel casing *d* is stiffened by internal ribs and is bolted to the flared axle tubes. These are supported at their outer ends in ball bearings, and the connection between the forged end-pieces of the wheelshafts and the wheel hubs are in the nature of slightly movable spur joints. To compensate for the lack of a service brake on the transmission, each wheel carries two separate brakes side by side, and their drums, 20 inches in diameter, are separately removable.

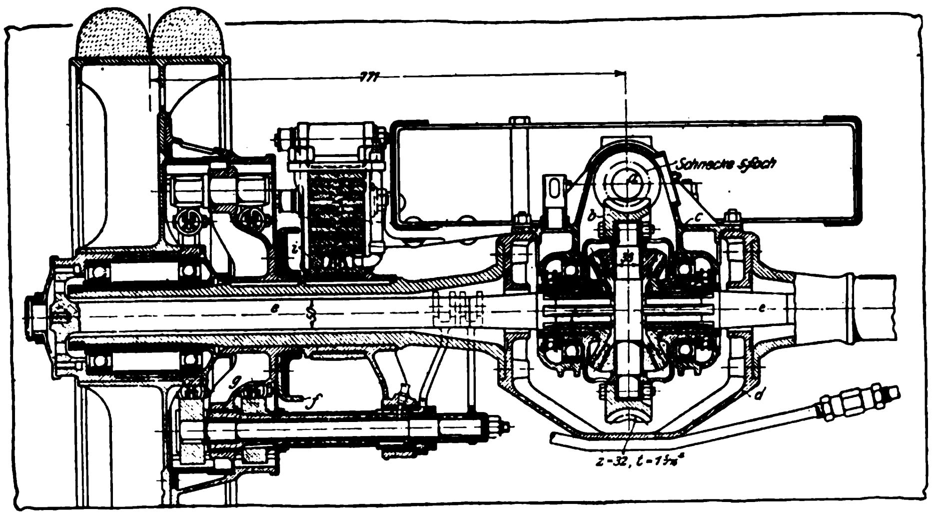

Fig. 8—Rear axle construction of German Daimler omnibus

The rear axle transmits traction thrust, as well as reactions from starting and braking, by two struts which are bent to an upward curve at their forward ends and susceptible of turning upon horizontal pins in the middle transverse of the frame. The rear ends *f* of the struts are rigidly secured to the brake-shoe carriers *g* which are pressed upon the rear axle. For further security the middle front portion of the rear axle is braced against a transverse *h* connecting the two struts as shown in Fig. 9, so that all torsions are taken up at this point and the pressed and wedged joints are relieved. The springs are also relieved of all traction and torsion stresses; their clip boxings are mounted with bushings which can turn upon the rear axle and are provided with special grease cups to prevent them from rusting on.—From *Zeitschrift des Vereines Deutscher Ingenieure*, August 8.

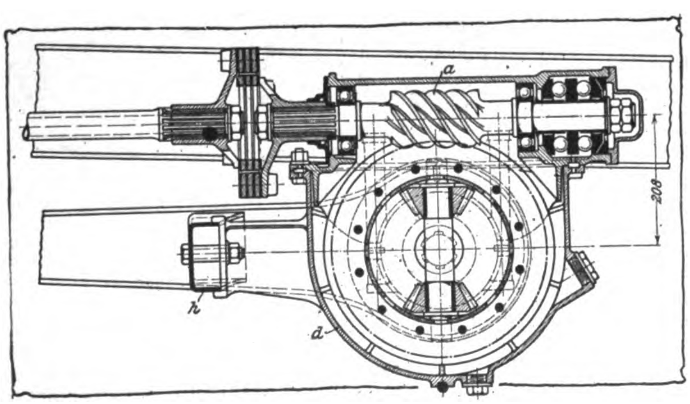

Fig. 9—Worm drive, showing also brace h for torsion struts

Recent Court Decisions —Father Pays Damages

Court says that an 11-year-old boy is so young that he is presumed to be inexperienced and unfit to drive a large automobile.

In a recent case a man sued because his wife had been run down and injured by an automobile driven by an 11-year-old boy. It appeared that the man sued had purchased the car for his son and allowed him to drive it; that the boy had used the car several months and had driven 3,000 miles.

The Court said that it was not willing to hold that a powerful, heavy machine, such as the one in question, in the hands of an 85-pound boy, not yet in his teens, speeding along the streets of a populous and busy town might not become a menace to the lives of the people attempting to cross the street in front of it. It further stated that an automobile could not be held to be a dangerous appliance as a matter of law, because they have grown to be a part of the life of the country and when properly handled, and driven, are useful and convenient vehicles. Judgment was given against the father, however, by the Court on the theory that the parent had not used reasonable care and should have anticipated an accident as a result of permitting the child to use the car.—*Allen vs. Bland*, 168 *S. W.* (*Texas*) 35.

Experiment Not Admissible

Man may not testify that, by experimenting with his automobile, he found he was able to stop within a shorter distance than a chauffeur stopped who ran down a person.

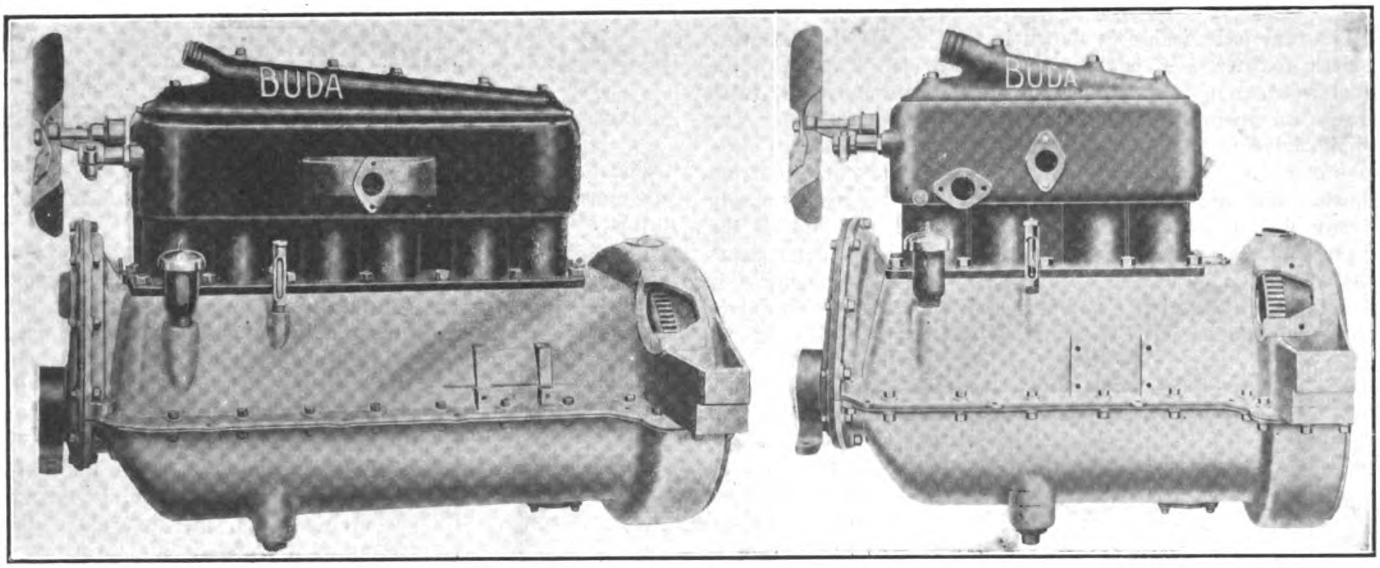
A man was injured in a collision between a carriage, in which he was riding, and an automobile, which was coming along the road in an opposite direction. The injured party endeavored to have a friend testify that he had experimented with his car at the place of the accident and had found that he could stop quicker at a given speed than the chauffeur had done.

The Court held that, as the conditions were not the same at the time of the accident as they were at the time of the experiment, the testimony was not proper, and that this evidence was particularly improper because the cars were not of the same make or of the same horsepower.—*Beckley vs. Alexander*, 90 *Atlantic* (*New Hampshire*) 878.

Owner Responsible for Family

In Washington an automobilist must pay damages to an injured person when his car is negligently driven by some member of his family.

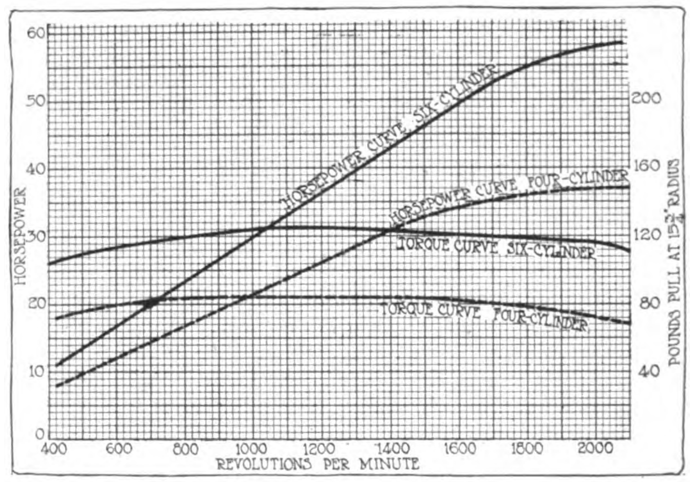
A motorcycle and an automobile collided at a street crossing and the motorcyclist was thrown and injured. The automobile was owned by a husband and wife as community property and was used by them together and also for selling real estate. The wife was not in the car at the time of the accident, but it was being driven by her daughter. The motorcyclist sued the husband and wife together for his injuries and the Court held that the owner of an automobile, who purchases the same for the use of his family, must pay damages to a third person who is injured through the negligent driving of any member of his family who has permission to drive the car.—*Switzer vs. Sherwood*, 141 *Pacific* (*Washington*) 181.



Left—Left side of new six-cylinder Buda motor showing clean exterior of block casting. Right—New four-cylinder Buda type. Note provision for attaching electrical systems to both models

Buda Brings Out New Four and Six

Both Block Designs of L-Head Type—Unit Feature Is Optional



Horsepower and torque curves of new four and six-cylinder Buda motors

TWO new power plants have been brought out by the Buda company of Harvey, Ill., manufacturer of the Buda automobile motors. Both of these are 3.5 by 5.125 inches, one being a six and the other a four. The design of the two is exactly similar throughout save for the number of cylinders. Both have their cylinders cast in a single block and are of L-head design.

Both Three-Point Suspended

The weight of the four, which is known as model "RU" is given by the manufacturer as 375 pounds with regular equipment. The six is stated to be 525 pounds with regular equipment, Both motors are designed for three-point suspension, and, although intended originally to be unit types, will be furnished without the unit feature if desired.

The cylinders are of gray iron and have been made with an extra large waterjacket space. To further insure efficiency in cooling, the water is baffled so that it is discharged from the pump directly beneath the valves and arranged to secure a complete circulation around each individual cylinder. The top of the cylinder is provided with a cover which can be removed, allowing for access to the upper part of the waterjacket space. The base flange of the cylinders is extended in the form of a shelf and the valve lifter guides are mounted in openings drilled in this shelf. This gives a compact arrangement for supporting the guide lifters and pushrods and provides for lubricating these parts by means of communication with oil from the crankcase.

Mudpan Hangs from Lugs

The crankcase is cast from aluminum alloy and divided horizontally into two parts. The upper part contains the complete crankshaft bearing supporting members and includes the entire bearing assembly. The lower half of the crankcase serves as an oil pan. A feature which will be appreciated from the standpoint of accessibility is the fact that lugs are placed on the crankcase to support the mud apron, doing away with the necessity of hanging this from the main frame.

In arranging the crankcase for the three-point suspension, the rear supporting members are two in number and are provided for by arms cast integrally with the upper half of the case and arranged to bolt directly to the main frame. The forward end of the motor is supported at the crank center by a trunnion bracket arranged to rest upon a dropped cross member of the frame. This means of support allows the bottom end of the crankcase to be removed without interfering with the upper part.

Clean Exterior Appearance

The exterior appearance has been kept clean by inclosing the valve mechanism, which is all on the right side of the motor, allowing plenty of room for installing the steering gear in left drive cars. The length overall of the six-cylinder motor from the face of the fan to the rear of the cylinders is 35 11-16 inches. This dimension on the four is 25 9-16 inches.

The pistons are cast iron ground to size and in accordance with up-to-date practice, are drilled with oil relief holes through recesses to prevent the lubricant from being drawn up into the combustion space, causing smoking and carbonization. The rings are cast iron, diagonally split eccentric. They are ground on the periphery and also on the sides.

Open hearth steel is used for the piston pins and these are case-hardened and finish ground to fit the pistons.

Open hearth steel drop-forged and heat-treated is also used for the connecting-rods which are I-beam section. These are machined and reamed to accurately locate the centers and are not offset. The upper end of the rod is bushed with phosphor bronze; the lower end is fitted with die-cast nickel babbitt bearings. Connecting-rod bolts are heat-treated steel.

Four main bearings are employed on the six and three on the four. The crankshaft is drop-forged open-hearth steel, heat-treated, machined and balanced on a Norton machine. The heat-treating process, according to the Buda company, gives the crankshafts a tensile strength of 120,000 pounds per square inch and an elastic limit of 85,000 per square inch. The dimensions of the three bearings on the four are as follows: Front, 1.75 by 2.875; center, 2 by 2.25; rear, 2.125 by 3.25. On the six the diameters and lengths of the main bearings are as follows: Front, 1.75 by 2.875; two centers, 2 by 2.25; rear, 2.125 by 3.25. In both motors the connecting-rod bearings are 1.875 inches in diameter and 2 inches in length.

Helical Timing Gears

Helical timing gears, cut on automatic hobbing machines, drive the camshafts. The timing gearset is composed of one crank, one cam and one pumpshaft gear which are accessible by the removal of the gearcase cover. The camshaft and cams are forged in one piece from open-hearth steel, machined and case-hardened. On the four the camshaft is carried on three bearings and on the six, on four. The cams are designed for quietness and are a modification of the sharp contour type, avoiding hammering between cams and followers.

Cooling is by means of a centrifugal water-circulating pump fitted with a bronze runner. The water pipes are exceptionally short and are designed to connect to the radiator without a bend in the hose. The fan is mounted on anti-friction bearings and has a belt-tension adjustment.

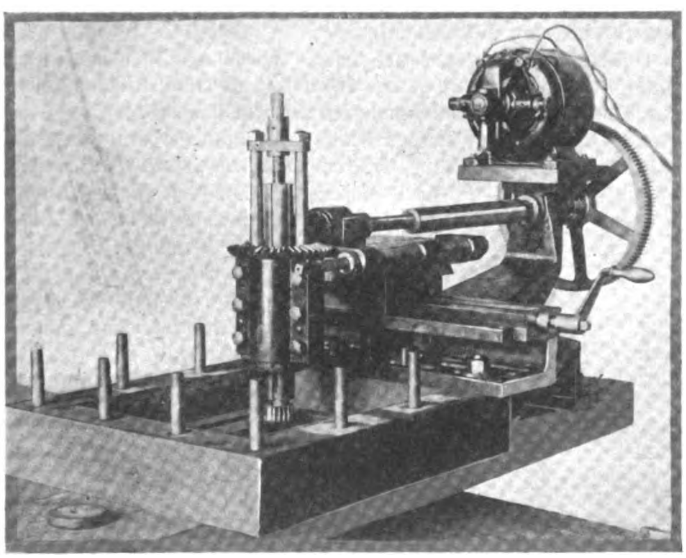
Force-Feed and Splash Lubrication

Lubrication is accomplished by force feed as regards the main bearings and by splash to the rest of the motor. The oil is pumped from the reservoir in the crankcase by a gear pump to the main bearings, the lead from the pump entering the top of the bearing and providing oil for the frictional surface at these points under pressure. Overflowing from the forward and rear ends of the main bearings, the oil enters the splash pockets and the dip of the connecting-rods into these provides the oil space which takes care of the cylinders and all other interior working parts. A separate lead takes a constant stream of oil from the pump to the timing gears.

Provision for Accessories

Provision is made for attaching most of the standard ignition starting and lighting systems. The clutch may be housed in the flywheel, which is attached to the crankshaft by a large flange with six steel bolts. The diameter of the flywheel in both motors is 17.25 inches. This follows the practice of making everything interchangeable on these two motors, reducing to the utmost manufacturing costs. In both engines the intake manifold is designed for a 1.25-inch carbureter. S. A. E. standards are used for connection of accessories, and the spark plugs are also to the society's dimensions, being 7-8 inch, 18 standard thread.

Portable Electric Milling Machine for Small Jobs on Heavy Work



Portable electric milling machine of new design manufactured by the Pedrick Tool and Machine Co., Philadelphia, Pa.

A PORTABLE electric milling machine can be used to good advantage for small jobs on heavy work. In this state of affairs it is much cheaper to carry the machine to the work rather than the work to the machine. Accompanying illustration shows the machine of new design that will be found very convenient for a great variety of purposes.

This is a portable electric milling machine suitable for being carried to the work and mounted on it. In this manner it can handle many jobs on an assembled part that would be exceedingly awkward on a regular milling machine and which in fact would generally require the dismantling and removal of the part upon which it is working.

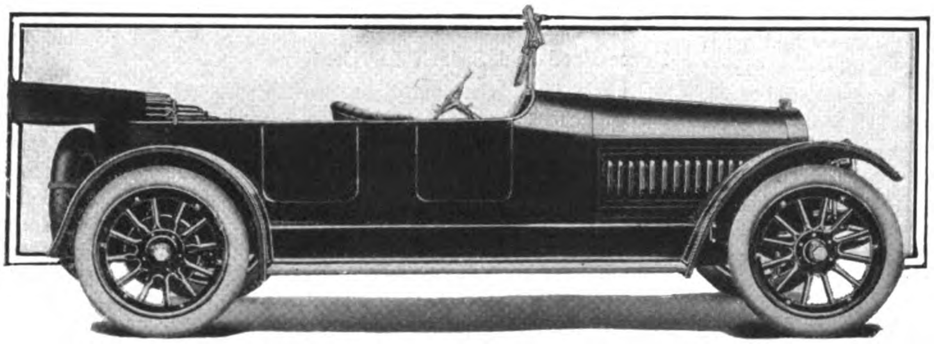
The particular job shown in the illustration is the milling of the seat and port edges of an engine valve. The method of mounting the milling machine is also clearly shown in the illustration. It is secured by means of bolts passing through longitudinal slots in the base. By the same arrangements the machine can be mounted vertically as well as horizontally.

One of the advantageous features of the milling machine is that the spindle stands clear of the base, rendering the work exceptionally accessible. The longitudinal travel of which the instrument is capable is 12 inches and the cross travel, 6 inches. There is a range of vertical of 6 inches. In place of the automatic adjustment generally used on the larger milling machines, hand adjustment is provided for by the longitudinal and cross travels. This is in keeping with the idea of rendering the machine as light as possible as it does away with the weight and complication necessary with the automatic adjustment.

Some of the purposes for which this milling machine may be used are the milling of engine and pump valve seats, port edges, key seating shafts, facing pads on large frames, etc. By manipulation it can also be made to perform other tasks, even drilling. A special attachment with V-shaped seats can be supplied for mounting the machine on shafts for key seating.

The driving power on the instrument is supplied by a .25-horsepower Westinghouse electric motor running at 1,725 revolutions per minute. The machine is manufactured by the Pedrick Tool & Machine Co., Philadelphia, Pa.

Pilot 55 Horsepower Six for $1,885



Pilot 55 horsepower model selling for $1,885

Fitted with Two and Five-Passenger Bodies— Two Other Models with 60 and 75 Horsepower Motors

THREE sixes make up the 1915 line of the Pilot Motor Car Co., Richmond, Ind. One of these, the 55, is an entirely new addition and takes the place of the four manufactured for the 1914 season, the other two, the 75 and 60, are continuations of the product of the present season.

The new six, which is the Pilot leader for the 1915 season, follows the latest dictates in six-cylinder design. Built on a chassis of 126 inches wheelbase, and fully equipped, it sells for $1,885 in two- and five-passenger bodies and for $100 additional in the seven-passenger. It is a big, roomy car of ample carrying capacity, 34 by 4-inch tires, has the popular 3.5 by 5.25 motor and cantilever springs.

Like all other Pilot cars the power plant is a product of the Teetor-Hartley Motor Co. of Hagerstown, Ind. The makers place a rating of 55 horsepower on this motor as measured on a torsion dynamometer. It is a T-head design with the cylinders cast in a block. Although the intake and exhaust manifolds are cast separately and are placed on opposite sides of the cylinders a very simple exterior has been maintained, as the valves and their operating mechanism have been inclosed by long cover plates.

Three-Ring Pistons

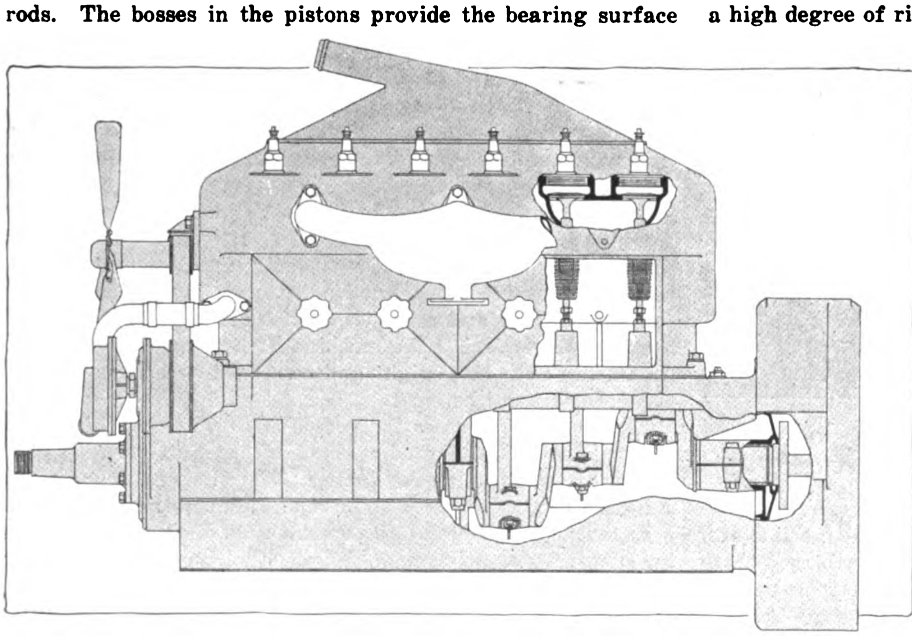
Three eccentric rings are fitted to the cast-iron pistons. These rings are ground on the piston as well as on the cylinder side to assure a minimum gas leakage. The piston pins are of chrome-nickel steel and are secured in the connecting-rods. The bosses in the pistons provide the bearing surface and the makers claim that a distinct advantage is gained in this, owing to the higher percentage of bearing surface as compared to the practice of fixing the pins in the boss.

The connecting-rods are of the standard I-beam section, drop-forged from carbon steel. In the Teetor motors the same grade of steel is used in the connecting-rods as in the crankshafts. The diameter of the bearing at the lower end of the connecting-rod is 1.875 inch and the length 2.25. Following the best practice, the bolts holding the connecting-rod bearing caps in place are of nickel steel. These bolts must take all the strain of the drive once in every revolution and manufacturers are almost without exception using alloy steel at this point.

Three Main Bearings

Three large main bearings lined with die-cast, nickel babbitt support the crankshaft. The front bearing is 2 inches in diameter and 3 inches long; center, 2.5 by 1 11-16; rear 2 by 3.5. All six crankpins are of course of equal diameter, this dimension being 1.875 inches. The main bearings are supported by the upper half of the aluminum crankcase so that the bottom pan of the motor can be removed without disturbing the bearing adjustments.

Helical timing gears are used. These are inclosed in an oil-tight compartment at the front end of the crankcase. On the Teetor motors the camshafts are not a drop-forging. Instead a special alloy is used which, the makers claim, possesses a high degree of rigidity, thus meeting the prime requirement of a camshaft. Die-cast nickel-babbitt bearings, the same material as used for the crankshaft bearings, are used for the camshafts. These bearings are three in number and of generous size. In fact the whole valve mechanism is of ample proportions. The valves themselves are 2.25 inches in diameter and have a lift of 5-16 inch. The push rod guides are 2.5 inches long.

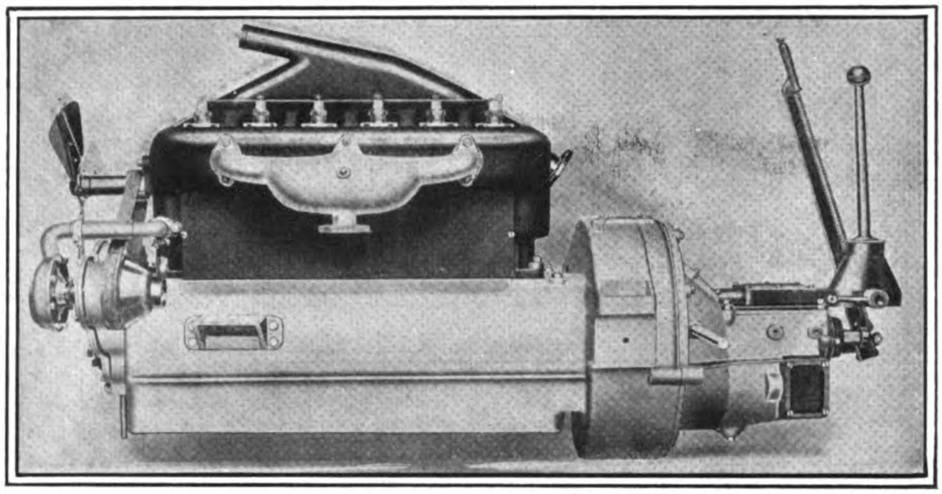


Pilot motor showing mounting of the pump at the front and the valve mechanism and crankshaft construction

Patented Splash Lubrication

Lubrication is by a patented splash arrangement. Two overflow oil basins into which the connecting-rods dip are fastened in the lower half of the crankcase. In the bottoms of these two oil troughs there are drilled holes which are of sufficient size to admit a definite quantity of oil. As the lubricant is circulated by the connecting-rods, it is replaced by the oil supply which is furnished through the oil holes. The faster the motor runs, the faster the oil is pumped to the splash troughs and an increase is given in direct ratio to the speed. The overflow from the bowls, as in all circulating splash systems, finds its way back to the reservoir in the bottom of the crankcase. A large oil gauge is placed close to the breather pipe.

A centrifugal water pump circulates the cooling water through a cooling system that has been carefully designed to be adequate as regards jacketing space. The radiator is a Mayo square-tube. The water pump has one feature that makes it of unusual interest in that it has but one packing gland instead of two. This reduces by 50 per cent. the chances of leakage at this point. The water chamber at the top of the motor is larger than usual as will be noted from a side view of the engine. It resembles very much a water header for a thermo-syphon system.



Unit power plant used in the Pilot 55. A Teetor 3.5 by 5.25-inch motor is employed

In equipping the cars electrically for this season the magneto has been dropped and in its place a combined lighting and ignition generator of Westinghouse manufacture has been substituted. The cranking motor is a flywheel installation and is also a Westinghouse. The lighting and ignition generator is mounted on the left side of the motor on a platform so arranged that the drive is taken from the pump shaft. A rather ingenious method of balancing the pump and generator drive has been made use of. Referring to the side view of the engine it will be seen that the water pump is mounted forward of the timing gear case. In this way the water pump shaft does not have to pass through the pump housing and the use of the single stuffing box as previously mentioned results. A further advantage is that the load on the bearing is equalized in a longitudinal direction.

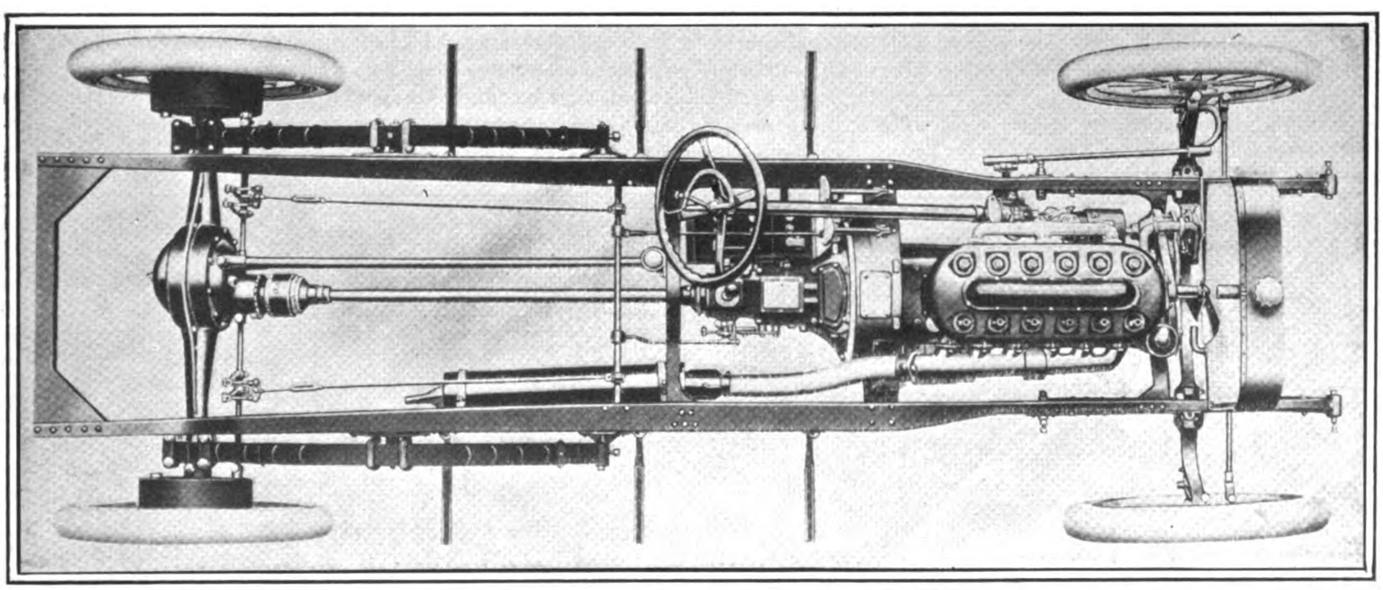
Gravity Feed to Carbureter

A gravity feed gasoline system is used. The tank has a capacity of 19 gallons and is located under the front seat. The angle in the tube leading from the tank to the carbureter is 15 degrees. This means that up to an angle of 15 degrees the last drop in the tank would pass through the system. The more gasoline there is in the tank in such a system, the greater the angle at which it will feed, but with this angle, with a pint of gasoline in the tank the flow would be as good as with the full 19 gallons up to an angle of 15 degrees. A feature in the economy of this car is the design of intake manifold. This is an aluminum casting so arranged as to give a balanced feed to all cylinders. It is provided with a gas chamber which will be noted in the side view of the motor.

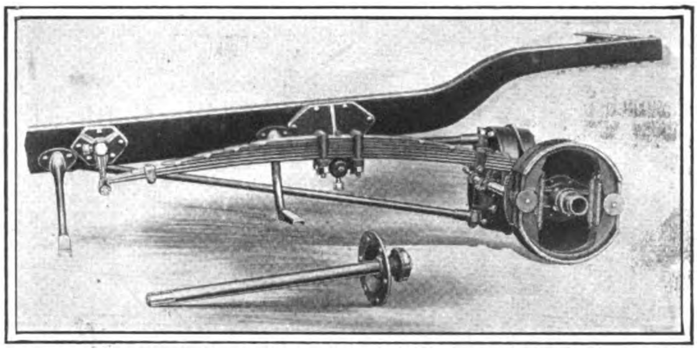
The clutch and gearbox are contained in a unit housing which is bolted against the rear face of the crankcase forming a unit power plant. Both the clutch and gearset are products of the Warner Gear Co. of Muncie, Ind. The clutch is a wide leather-faced cone with engaging springs and provided with a ball thrust to take the load of the engaging spring off the crankshaft of the motor. The gearset provides three forward speeds and is provided with gears of chrome vanadium steel.

The drive shaft is fitted with a universal joint at each end. The units on the drive from the gearbox through the rear axle are all of 90 horsepower capacity. The heavy construction is carried even to the housing of the rear axle which is of 7-32 inch pressed steel. This is unusually heavy as it is common practice on many cars of sturdy design to use 5-32 inch material here. The axle is floating and is a special Pilot design manufactured in the Hess shops.

Nickel steel gears and chrome-nickel steel shaft are used in the differential. The shafts are 1.5 inches in diameter and the rear wheel bearings have a guaranteed load capacity of 7,800 pounds. This is exceptionally heavy construc-



Pilot 55, six chassis showing mounting of motor and drive mechanism. Note connection of torque member and cantilever rear springs



Cantilever spring suspension and torsion bar arrangement on the Pilot 55

tion as the makers claim a weight of but 3,150 pounds for the entire car, fully equipped.

A double set of internal expanding brakes act on drums bolted to the 34-inch artillery wood wheels. The tires are 34 by 4 all around.

The frame construction is of particular interest in the Pilot car because, as in the rear axle, especially strong materials have been used. The frame stock is 7-32 inch thick and the channel webs are 5 inches deep. The flanges are 3.5 inches in width with reinforced front ends and at the rear is braced against racking with heavy gusset plates. Ample provision of strength has been made against the three causes of frame downfall; racking, crystallization and sagging.

The cantilever rear spring used in the new six is an innovation for the Pilot concern. Previous products of this company have been fitted with semi-elliptics. The springs used in all the Pilot line though are distinct in that use is made of the imported English Sheffield steel.

The other two sixes have larger motors than that in the car just described. On the 75 there is a 4.5 by 6 Teetor power plant with T-head cylinders. This car has many of the general features of design that are incorporated in the little six. It has the cone clutch, Warner gearbox, and the same type of drive. The rear axle, however, is a Timken and the units are larger to accommodate the more powerful motor and the longer wheelbase of 132 inches. The tires on the 75 are 37 by 4.5, both front and rear. Center control is used on this car, but the purchaser has his choice between left or right drive. The price of this car fully equipped in either two, four, five, six or seven-passenger body types is $2,885. The colors are optional although plain blue, brewster green, brewster green with ivory panel or violet with ivory panel are standard.

The Pilot 60, known as the Empress model, has also the T-head block Teetor motor. In this instance the bore is 4 and the stroke 6 inches. It is built in seven-passenger and roadster bodies and fully equipped sells for $2,585.

This model is essentially the same as the 75, being mounted on the same chassis. The axle is smaller in the 60 but is of Timken manufacture and the radiator which is a Mayo the same as in the larger car has a .5-inch shallower core than is necessary with the larger engine. A choice of left or right drive is offered in this car also. The Empress model as well as the 75 has undergone a change in the electrical equipment for this season being now fitted with the Westinghouse two-unit system in which the generator performs the function of ignition as well as lighting.

Marr Car, Weighing 600 Pounds, Has Sliding Gears and Shaft Drive

As an example of the refinement and finish to which the building of a small car can be carried, the little machine which Walter S. Marr, engineer of the Buick Motor Co., has made after his own ideas and for his own personal use is noteworthy. Although the Marr car was not built with the specific idea of manufacturing it for the public, if it were placed upon the market it would no doubt meet with ready sale. Its total weight is about 600 pounds.

The little car has a 36-inch tread, and 100-inch wheelbase. Its motor a four-cylinder water-cooled type 2 3-4 by 4 inches. The car is in every way up to standard in design, and has a sliding gearset and shaft drive back to a regulation type of rear axle with differential. The frame is of channel section pressed steel and springing is well taken care of by long semi-elliptics front and rear. Even the front axle is in accord with standard practice, for it is a small I-beam drop-forging with the usual form of yokes to carry the steering spindles.

Its body, an attractive little affair, is arranged for tandem seating. The cowl slopes into the bonnet and this meets the pointed radiator in unbroken lines. The radiator is finished in German silver. Finished in buff with brown leather upholstering to match, this little car would soon become the envy of many if it were on the streets of our cities, its price would be prohibitive unless made in large quantities, for it has every appointment that any machine can boast of.

Deep Turkish cushions are fitted, and the driver's compartment is roomy and comfortable. One special feature is the adjustable steering wheel which may be raised or lowered on its spindle to meet the requirements of the driver.

A speedometer and clock together with the spark and throttle levers are placed on the leather-covered instrument board, and at night they are lighted by an electric dash lamp. The control levers are at the right. Due to the narrow width of the car, the steering wheel is in the center.

Present Time Is Opportune for Increasing South American Trade

But We Must Go About Developing It Calmly and Sensibly, Prominent Speakers Tell Merchants' Association

NEW YORK CITY, Oct. 16—Nearly 1,000 business men assembled at the Hotel Astor on Wednesday at the call of the Members' Council of the Merchants' Assn. to consider the problem of extending our trade in South America. Many foreign consuls-general and representatives of the South American republics were present. The speakers were: W. S. Kies, manager of the foreign trade department of the National City Bank, which is establishing branches in the financial centers of South America; John R. Fowler, second vice-president of W. R. Grace & Co., and Charles M. Pepper, government expert on South American trade.

One of the most interesting addresses was that of Mr. Fowler on the present situation in South America. A brief digest of this follows:

"We commonly hear South America referred to as 'that country down there,' with no appreciation of the fact that it is really a great big continent, comprising quite apart from its three European colonies, ten distinct Nations, nearly all of very large area and no two of which are quite alike climatically, commercially or financially.

"Before the present war broke out, nearly all of South America was suffering from business depression and, of all the grand divisions of the world, apart from Europe itself, this sudden upheaval has struck South America the hardest blow and left those countries just bewildered. For they have always depended upon European money for government loans, public works, railway construction, industrial developments and all such enterprises.

Financial Troubles

"If we briefly review the countries, as before the war, we find that Brazil was already in a precarious financial situation, but expected relief from a large foreign loan which will not now come off. Her Amazon district is in a desperate condition from the low price of rubber. As to coffee, its market price has recently declined 30 per cent. to 40 per cent. and, moreover, she is temporarily without Europe as a taker of about 40 per cent. of her crop.

"Both Colombia and Venezuela suffer correspondingly in coffee, for which Hamburg formed a very important market.

"Argentine was in a critical commercial shape. She depends upon Europe as the main buyer of her great grain crops and also of her big wool clip.

"The great staple of Chile is nitrate of soda, of which article she produces about 3,000,000 tons annually. Of this Europe takes about 2,000,000 tons, so Chile has temporarily lost her market for two-thirds of the article, and this fact has quite demoralized that industry. Her copper industry is also afflicted.

"Peru is also a big producer of copper and suffers accordingly. She is helped by the big rise in sugar, but on the other hand, suffers from the fall in cotton.

"The principal export from Ecuador is cocoa, which has fallen about 33 1-3 per cent. in price, and is temporarily without Europe as a buyer.

Buying Power Crippled

"We must realize that the buying power of these South American countries has now been terribly crippled and will remain so for much time to come. Furthermore, all European export to South America is by no means shut off.

"In seeking trade relations, we usually overlook that barter is a good principle, and that hitherto our own Tariff might well be considered as 'in restraint of foreign trade.' Formerly, we tried to exclude everything that we absolutely had not to obtain abroad, but our new Tariff bill is something like an invitation to 'trade both ways,' and a sign that we are prepared to do more bartering.

"The present, therefore, is a particularly opportune time to develop our trade with South America; but we must go at it sensibly, earnestly and not hysterically.

"It is European capital that has always stimulated those countries, but if American capital can assist them in their present financial dilemmas our trade will be helped immensely, for it is money that keeps trade alive. And American money would naturally get us business where European capital has formed the habit of demanding a preference for European goods. Can we now help South America financially?

"Another circumstance, this time of a happier nature than war, is the compliment felt by the three leading South American nations upon being invited to join us in discussion of the International question of Latin America. And the elevation to the rank of Embassies of our diplomatic intercourse with Argentine, Brazil and Chile, is a new dignity offered by us to those countries, which is profoundly appreciated by them.

Liberal Credits

"We are often reproached on the score of niggardly credits to South American customers, but the fact is that our exporting merchants are really very liberal in credits to South America, much more so than our home merchants would concede to domestic trade. In spite of all we hear to the contrary, this affair of South American credit is just about the same whether the goods are from Germany, England or from the United States. For the worthy South American trader gets about the same facilities for payment, in one or another form, whether he buys from the United States or from Europe.

"The manufacturer properly wants cash to keep his business going, and it is the exporter who has to finance the foreign customer.

"It is always the unworthy customer that howls the loudest when the cautious merchant will not grant him dangerous terms; and this statement holds good whether the customer be in New York or Chicago, or Buenos Aires.

Shipping Facilities Good

"Perhaps it will surprise many to learn that our trade with South America is relatively as well served with shipping facilities as are the principal ports of Europe or Asia or Africa. In recent years, from New York alone, we have averaged fully three steamers weekly with general cargo to the River Plate ports, about semi-weekly to Brazil, and weekly to the West Coast by way of Magellan. In addition, the nearby countries have frequent service and the West Coast has had three lines connecting with us at Panama.

"And the ocean rates to ports 4,000 to 6,000 miles distant have been little, if any, more than we have to pay in domestic trade to ports only 600 or 800 miles away."

Demonstrations

DEALERS selling gasoline and electric trucks are still undecided as to whether it pays to demonstrate or not, in spite of the much valuable information that has been made public on this point. One large maker recently announced that when giving free demonstrations it made but one sale out of eighty-one demonstrations. Under a régime of charging for demonstrations it sold trucks to 87 per cent. of those to whom demonstrations were made. Under a régime of no demonstrations its business continued and made good increases.

Why should it be necessary to demonstrate a known quantity? We do not ask for demonstrations of new machines that we put in our factories or garages. When we buy them we expect that they will do certain work, otherwise we would not buy them.

Why should a central station company purchasing an electric truck ask for a demonstration, when its business is so closely allied with electric motors and batteries, the only two factors that might possibly give trouble in an electric machine. These same people do not buy electric generators on any principle of competitive demonstration, yet when it comes to buying a truck they expect, in fact, request, competitive demonstrations. They expect to get free demonstrations.

The $500 Electric

THE continued agitation from many quarters for a cheap electric passenger vehicle, one retailing in the zone of $500 or $700, does for the time being seem a conception but very little of a reality.

Practically every effort to date to produce such a vehicle has ended in signal failure, and those devotees of the electric, who have been refraining from purchasing until the $500 vehicle appeared, had better purchase if they want to derive any benefit during the next few years from the electric vehicle.

As to whether such a vehicle is a possibility of the semi-distant future is a matter of grave conjecture as there are so many apparently insurmountable obstacles to its achievement today as to make it a question of doubt as to whether such a vehicle will ever be built to meet the requirement of the public.

There are, in reality, two factors that render such a vehicle impossible today. First: It is practically impossible to build such a machine and make it meet the requirements of the people. An electric selling at $500 is not an impossibility to build but its radius of mileage on one battery charge would be limited to 25 or 30 miles and its speed would not exceed 15 miles. At the present time such a vehicle will not meet the requirements of our fastidious people. They want more mileage and they want more speed. Our cities today are too large in area for such a vehicle.

Electric manufacturers are apparently united in the one opinion that the public of today does not want such a vehicle, in fact, they say they have canvassed the makers of electric current in the leading cities, and that the majority of them would not make use of such a machine. Today the public is asking for increased mileage radius per battery charge, the radius of 50 or 60 not being enough, many asking for 85 and 100 miles per charge.

This demand for greater radius is not that such a mileage is used in the majority of trips, but the users want a feeling of confidence, a feeling that in the worst weather, when he needs his machine most, that he will have ample current and power to get him over his route and on schedule.

Quantity production has been the great secret of price reduction in the gasoline car field, and the doubting Thomases are asking why cannot similar reductions be accomplished in the electric. It may be possible, but at present the demand for such a vehicle does not seem large enough to warrant the investment that would be necessary to manufacture it on such a scale.

In the meantime gossip, and a few pioneering efforts, have set a high mark for the electric manufacturers to aim at; and, if it is true, that the existing electric of today with its large radius per charge, its long wheelbase, its reserve power and its luxurious equipment and furnishings can perform practically 98 per cent. of the work that the gasoline car does, it is only natural that the electric manufacturers push to the limit their present product which has been developed to meet the demands of the public.

Advocate Michigan Law for All States

Committee on Uniform Automobile Regulation Considers Statute at Present Void Most Suitable for Adoption

WASHINGTON, D. C., Oct. 17—One of the big subjects to be discussed by the delegates to the conference of commissioners on uniform state laws, now in session here, is a uniform motor car law, which has been prepared by a special committee. The committee has adopted the statute in force in Michigan as the basis for the model law it proposes that the conference shall indorse and recommend to the legislatures to pass in all the states.

It is a lengthy bill and provides for the registration, identification, regulation and taxation of motor vehicles operated upon the public highways and of the operators of such vehicles. Some features of it are the furnishing of registration lists to county clerks; re-registration annually; changing of color of number plate annually; special registration by manufacturers and dealers; exemption of non-resident owners other than corporations; registration of chauffeurs and wearing of chauffeur's badge; unregistered chauffeurs not permitted to drive; certifying convictions of violation of law, etc.

The report of the committee on the proposed uniform law is in part as follows:

The reason for adopting the statute of another state as the basis of a uniform law loses some of its force from the fact that this Michigan statute was held to be unconstitutional by the supreme court of that state in March, 1914, which decision is reported in Vernor against Secretary of State, 146 N. W., 338.

However, upon inspection of this decision it will be found that there is no fault in the body of the act, but its invalidity was placed upon the ground that under the constitution of Michigan the title of a statute must clearly indicate the purpose of law, which the title to this act failed to do, it providing only for "registration, identification and regulation of motor cars" under the police power of the state, when it was, in fact, a taxation measure under the taxing power of the state. However, this defect of the statute is remedied by broadening the title to cover the subject matter of the law, which your committee has done in the proposed bill, so that it may meet the requirements of the constitutions of the several states which have provisions similar to that of Michigan.

Michigan Will Re-Adopt Law

That the Michigan statute will be re-adopted by that state, with perhaps some slight modifications, is the opinion of the chairman of this committee, who is a resident of Michigan, and the tentative action taken by this conference may be of benefit to the legislatures of the several states, including the state of Michigan, who may be called upon to act in the adoption or amendment of motor car statutes in the coming year.

While we have presented the Michigan act in its entirety, we are not in favor of the adoption of all of its provisions and have placed footnotes to some of its sections, indicating our view in relation thereto.

Bankers Recognize Automobile Industry

RICHMOND, VA., Oct. 17—Worthy recognition of the automobile industry was furnished at the annual meeting of the American Bankers' Assn. here recently in an address by William Livingstone, president of the Dime Savings Bank of Detroit, on "Twelve Years of Continued Progress—the True Status of the Automobile Industry" in which for the first time at one of these bankers' gatherings there were favorable words for the automobile, its builders and users.

There were more than 2,000 bankers from practically every state at the meeting in Richmond. Alfred Reeves, General Manager of the National Automobile Chamber of Commerce, was also present to supply any facts and figures that might be required.

Mr. Livingstone showed that there were more than 435,000 cars sold during the year ending June 30, and that even in depressed times there had been continued buying of cars, supplying proof that they are a growing necessity of our modern civilization. Bankers had fostered a growing industry through co-operation with manufacturers and dealers and he explained in detail the method of making and marketing cars. Not alone did he furnish figures for the past but he indicated the future fields for the motor car and the possibility of increasing the sales both here and abroad.

Among the interesting figures brought out by the Detroit banker was the fact that there are 1,400,000 cars in use in this country, with an approximate figure of 450,000 cars as a production for the next 12 months to be sold by 15,500 automobile dealers. He said there were 13,630 garages; 1,280 repair shops and 680 supply houses. There are 450 listed manufacturers of motor vehicles, including 170 making gasoline pleasure cars; 245, gasoline commercial cars; seventy-seven, light cars; twenty-seven, motor fire apparatus; eighteen, electric pleasure cars; twenty-four, electric commercial vehicles.

Willys-Overland Business Breaks Records

TOLEDO, O., Oct. 21—*Special Telegram*—To show that the war is not affecting the automobile business to the extent some people claim, the Willys-Overland Co. reports that the week ending October 17 was biggest in its history, 1,400 cars valued at more than $1,300,000 being shipped, exclusive of trucks, etc.

October 15 unfilled orders for cars for $4,500,000 were on hand, one-third increase over the corresponding day last year.

Since the start of the fiscal year in July 11,400 cars have been shipped up to October 15, or 40 per cent. more than the corresponding period last year and 500 per cent. increase over 2 years ago.

Average daily shipments are 250 cars, men being employed and in some departments work is kept up 24 hours.

Since July 1 sales abroad are 75 per cent. of what they were in the same period a year ago, while average daily shipments to foreign countries represent in value $10,000.

Sales Good at N. Y. Electrical Show

NEW YORK CITY, Oct. 20—Not only has the present electrical show held at Grand Central Palace been more of a success than was anticipated, considering present financial conditions, but it has actually been the cause of more sales than any previous show. This is the consensus of opinion as expressed by the exhibitors of electric automobiles, and accessories. More people have attended the show, more interest has been shown in the displays than heretofore, more prospects have been obtained, and more sales actually closed.

As an example, one concern sold eleven electric pleasure cars. Strange to say, the war was given as a reason for practically all of these sales. It was stated that most of these machines were bought by the ultra-rich, those who were accustomed to drive the largest cars and employ the most expensive chauffeurs. Financial stringency forced those people to economize with the result that the chauffeurs were discharged, the big cars sold and electrics purchased, the need for chauffeurs not being so urgent in the operation of electrics.

Vanderbilt and Grand Prize Cups Offered

NEW YORK CITY, Oct. 19—The Motor Cups Holding Assn. has granted permission to the Panama-Pacific officials to put up both the cups for the Vanderbilt and Grand Prize races on February 22 and March 7, respectively. Up to the present time no official sanction has been given by the A. A. A. or the A. C. A., but it is expected that now, that the Motor Cups Holding Assn. has given its permission to hang up both cups, both sanctions will be forthcoming.

According to present plans the Vanderbilt race will be for automobiles of 600-inch piston displacement, or less, the minimum weight to be 1,600 pounds. The distance to be covered will be 300 miles. Cash prizes have been offered in addition to the cup. The winner will receive $3,000; second, $2,000; third, $1,500; fourth, $1,000, and fifth, $500.

The Grand Prize distance is 400 miles. Cash prizes will also be awarded in addition to the cup, donated by the Automobile Club of America. The winner will receive $3,000; second, $2,000; $1,000 to third, $1,000 to fourth and $500 to fifth.

The entry fee covering both races is $250. Entries close at midnight, February 10, 1915.

Barney Oldfield has expressed his desire to enter both races. He will drive a Stutz. Up to the present time no official entry has been made.

Exports for Fiscal Year Total $40,000,000

Remarkable Decrease in August Following Outbreak of War Exports Falling to 451 Cars

WASHINGTON, D. C., Oct. 19—At the request of many American motor car manufacturers the bureau of statistics, Department of Commerce, today made public figures showing the distribution of American automobiles, both pleasure and commercial, together with parts, during the fiscal year ended June 30, 1914. In that period outward shipments, including automobiles, engines, tires, parts, etc., reached the high record total of $40,000,000. It is noted, however, that a remarkable decrease occurred in August following the outbreak of war in Europe, exports in that month having fallen to 451 automobiles and motor trucks, compared with 2,004 in August of last year.

The following statement contains a complete record of the exports of motor trucks and passenger vehicles in the year ended June 30, 1914:

	Commercial Motor Vehicles		Passenger Automobiles		†Parts
	Number	Value	Number	Value	Value
Exported to					
Europe	249	$248,716	13,108	$10,168,218	$1,830,560

*Automobiles of all kinds included under "passenger."

†Exclusive of tires and engines.

Note—Under all other Europe are included: Greece, 1 commercial, $1,800; 25 passenger, $28,256; Turkey, 1 commercial, $2,000; 35 passenger, $21,052; also the following passenger automobiles: Azores and Madeira, 20, $10,771; Bulgaria, 43, $21,679; Gibraltar, 64, $33,030; Iceland, 5, $2,488; Malta, etc., 1, $422; Roumania, 28, $17,018; Servia, 4, $2,843; and Ireland, 2, $1,598. Under other North America, Newfoundland, 1 commercial, $1,221; 5 other, $2,761; Dutch West Indies, 1 commercial, $595; 13 other, $9,605; Santo Domingo, 1 commercial, $1,800; 11 others, $15,195; and a total of 9 passenger cars valued at $8,368 to British Honduras, Haiti and the Danish West Indies.

Market Reports for the Week

Market prices this week were generally lower, especially in the metals markets. Extreme dullness continues for refined copper and the tone of the market is easier, yet with scarcely enough business to indicate the exact position of prices. Electrolytic, though coming down $0.00 1-5, remained constant at $0.11 3-20 per pound, from Thursday on. Antimony is active and strong at $0.10 1-2. Tin had a fluctuating week of it, with a drop of $0.25 per 100 pounds. Only moderate buying is reported, and that by domestic consumers. Lead was quiet but steadier. The oils and lubricants markets were more or less steady, with a few drops in prices. Linseed oil came down to $0.47 at a drop of $0.02 while cyanide potash dropped to $0.25 per pound at a loss of $0.03. Cottonseed oil closed at $5.10 a barrel, or $0.18 below the opening price. Fine Up-River Para rose to $0.66 at a gain of $0.02. A fair demand is reported for crude rubber and the market was firmer in tone, especially for Brazilian, supplies of which are reported to have diminished recently.

Clayton Trust Bill Becomes a Law

WASHINGTON, D. C., Oct. 16—President Wilson signed the Clayton Trust Bill Thursday, Oct. 15. Two sections affect merchandising interests. One prohibits discrimination in price between purchasers when such discrimination tends to lessen competition or create monopoly. This section, however, permits grade, quality and quantity discriminations and permits price differences due to difference in selling or transportation costs. In the same community discrimination is permitted if made in good faith to meet competition. The seller is also permitted to select his own customers or dealers, when not in restraint of trade.

Another section prohibits the selling, leasing or fixing the price on any manufactured article on condition that the buyer or lessee shall not use or deal in a rival product. Interlocking commercial directorates are forbidden and no director, after the act has been in effect two years, shall be a director in two or more corporations any one of which has stock, surplus and undivided profits of more than $1,000,000.

Directors in offending corporations may be fined $5,000 or imprisoned.

Claims Infringement on Tire Cover Patent

NEW YORK CITY, Oct. 19—The Allen Auto Specialty Co., New York City, filed suit this week in New York against E. G. Baker, charging infringement of the Benjamin Nathan tire cover patent No. 799,662. Baker, who is located in the United States Rubber building, is a representative of the Gilbert Mfg. Co., New Haven, Conn., a tire cover maker.

Packard Production Passes 25,000 Mark

3,612 Vehicles Built in Company's Fiscal Year—Complete Balance Sheet

DETROIT, MICH., Oct. 15—With the ending of the fiscal year of the Packard Motor Car Co., August 31, 1914, another event took place in the concern's history. It was the passing of the 25,000 mark as far as the production of Packard motor cars and vehicles is concerned, for on that day exactly 25,028 Packards of all kinds had been built, during the 11 years the veteran company has been in the business.

Less cars were made during the business year just ended, all told, 3,612, which is 382 below the Packard record production of the previous 12 months. The Packard production, year by year since it started manufacturing was as follows:

1903-4—192	1907-8—1,470.	1911-12—3,617.
1904-5—481.	1908-9—2,669.	1912-13—3,994.
1905-6—768.	1909-10—3,990.	1913-14—3,612.
1906-7—1,188.	1910-11—3,047.	

Referring to an increase in the common stock a year ago the report says:

"At the annual meeting of the company a year ago, an increase in the common capital stock from $5,000,000.00 to $8,000,000.00 and of the preferred capital stock from $5,000,000.00 to $8,000,000.00 was authorized by the stockholders. This increase in authorized capital stock was made by reason of contemplated steps, some of which, on account of the generally depressed condition of American industry, have been postponed or abandoned, at least for the present, and we have been able to provide funds for our necessities, such as additional machinery, shop charges, experimental model development, etc., in the ordinary course of the business of the company, in preference to the payment of dividends on the common stock.

"So therefore no additional issue of the increased preferred stock thus authorized at the last annual meeting has been made. None of the increased common stock authorized has been sold except to a small extent, actually only $65,300.00, which the stockholders to whom the offering was necessarily made according to law had a perfect right to and did avail themselves of their privilege to subscribe for at par. All the other stockholders of the company, at the request of the managing officers, refrained from subscribing to this common stock, leaving it a treasury asset and available for the future wants of the company in the discretion of the directors.

"The directors, however, did feel that the common shareholders had a right to have represented in common stock in their possession a reasonable part of the surplus accumulated in past years, which on August 31, 1913, amounted to $3,006,256.22, and therefore in October, 1913, they distributed to the common shareholders $2,000,000 of the common capital stock from the $3,000,000 of common capital stock provided at the annual meeting last year, and thus decreased the accumulated surplus to that extent."

The annual statement, given in brief in THE AUTOMOBILE last week, shows the total receipts for the fiscal year ending August 31, 1914, to be $14,295,238.25, as against total disbursements of $11,832,773.80, leaving cash on hand on that date $2,462,464.25. The complete balance sheet follows:

ASSETS

PLANT: AT COST LESS DEPRECIATION—		
Real Estate—at cost	$285,864.21

Voiturette Creditors Approve $100,000 Offer

DETROIT, MICH., Oct. 20—At a meeting of the creditors of the bankrupt American Voiturette Co., they approved of the offer of $100,000 cash which has been made by the Samuel L. Winternitz Co., Chicago, for all the property excepting real estate, accounts, notes and cash. The receiver, the Detroit Trust Co., has petitioned Judge Tuttle, of the United States District Court, to allow the sale to take place.

According to reports, it is the intention of the Winternitz company to continue the manufacture of the Car-Nation and Keeton cars.

Chalfant Is Secretary of Electric Makers

NEW YORK CITY, Oct. 21—E. P. Chalfant has been appointed secretary of the Electric Automobile Manufacturers Assn., an organization of makers of electric passenger vehicles. Mr. Chalfant will open a general office in Chicago and devote his entire efforts to the interest of this organization which has been in existence for several years. At present the membership includes such manufacturers as Anderson, Baker, Ohio, Rauch & Lang, Waverley and Woods. It is expected that the membership will soon be more than doubled.

Mr. Chalfant is well known to the automobile industry in that he was general manager of the Assn. of Licensed Automobile Manufacturers 1908-1909. He was general sales manager for the Packard company during the next 2 years and from that company went to the Thomas Motor Car Co.

E. V. A. A. Elects Officers and Directors

PHILADELPHIA, PA., Oct. 21—The annual election of officers for the Electric Vehicle Assn. of America was held in this city today at the completion of the Fifth Annual Convention of the Association. The officers elected were: President, J. F. Gilchrist, Chicago; vice-president, Walter H. Johnson, Philadelphia; treasurer, H. M. Edwards, New York. Four new directors were elected as follows: F. W. Smith, New York; C. Blizard, Philadelphia; E. P. Chalfant, Chicago; and J. H. McGraw, New York. Of these officers, practically all are representatives of central station interests except Charles Blizard, of the Electric Storage Battery Co., and Mr. McGraw, the New York publisher.

175 Cars on View at Pittsburgh Show

First Fall Display Opens —75 Accessory Exhibitors —Good Business Done

PITTSBURGH, PA., Oct. 20—The ninth annual show of the Automobile Dealers' Assn. of Pittsburgh, Inc., is on at the Motor Square Garden, East End, this week. This is the first fall exhibition of automobiles in this city. More cars are being shown than ever before in this city and fully 175 individual cars are on display. There are also seventy-five displays of automobile accessories. Limousines and other inclosed types predomniate.

The exhibits in general emphasize the predominance of electric equipment for starting and lighting, the popularity of the six cylinder car, the appearance of the first American eight-cylinder car, the increasing number of makes using wire wheels, the big gains in safety appliances, the using of demountable rims on all cars and the prevalence of the left hand drive. About four-fifths of the cars are gasoline propelled. The show occupies about 30,000 square feet of space and exhibits are estimated at over $1,000,000.

The show is in charge of Ray P. McAllister and Earl Kiser. Sales of new models were nearly or quite as large as last year and in second-hand cars a better business was done.

Boston to Have Another Electric Show

BOSTON, MASS., Oct. 17—Boston is to have another Salon at which electric cars exclusively will be displayed. Plans have been completed for a 5 days' show at the Copley Plaza Hotel beginning November 2nd and ending the 6th. Already space has been alloted to fourteen different makes, and applications are pending from ten or twelve more. This will make it a larger electric show than the first one which was held at the same place a year ago.

Non-Members Apply for Show Space

NEW YORK CITY, Oct. 19—The National Automobile Chamber of Commerce, Inc., has on hand many applications to exhibit at the New York and Chicago shows, from accessory companies, which are not members of the accessory organization. There are eighty-five applications from such concerns for the New York show and fifty-six for the Chicago show. Additional applications are being received every day, and it is expected that allotments of space to these exhibitors will be made in a week or 10 days.

To Form the Associated Garages of America

CHICAGO, ILL., Oct. 19—A call has been issued by the Garage Owners' Assn. of Illinois for a convention to be held in this city during the automobile show in January, on the 27th and 28th, for the purpose of forming an organization on broad national lines. The name suggested for the new body is the Associated Garages of America.

The national convention will tread on the heels of the Illinois State Convention. The latter is called for January 26.

Seven New Members for M. & A. M.

NEW YORK CITY, Oct. 19—At a recent meeting of the Board of Directors of the Motor and Accessory Manufacturers, the following named concerns were elected to membership:

The Bearings Co. of America, manufacturer of ball bearings, universal joints, etc., Lancaster, Pa.; the Bock Bearing Co., manufacturer of Bock taper roller bearings, Phillips avenue and Michigan Central Railroad, Toledo, O.; Dreadnaught Tire & Rubber Co., manufacturer of automobile pneumatic tires, Munsey Building, Baltimore, Md.; Golde-Patent Mfg. Co., manufacturer of automobile tops, windshields, and other supplies for automobiles and carriage trade, 509-515 West Fifty-sixth street, New York City; L. P. Halladay Co., manufacturer of shock absorbers, bumpers, ignition devices and small specialty, Streator, Ill.; Robert H. Hassler, manufacturer of shock absorbers, West Tenth and Canal streets, Indianapolis, Ind., and Sloan & Chace Mfg. Co., manufacturer of a device combining air cranking and compressing to be sold by The Motor-Compressor Co., corner Sixth avenue and Thirteenth street, Newark, N. J.

Wilson Co. Announces New Truck

DETROIT, MICH., Oct. 19—The J. C. Wilson Co., long identified with the vehicle business of the city, and since the inception of the automobile, being principally associated with the automobile painting and trimming field, has made public the details of its 1 1-2-ton motor truck which has been in the process of experimentation and development for several months. The price is set at $1,800.

Construction of the first lot of trucks is now under way at the plant at Cass and Adams streets which is to be given over to this branch of the concern's business, the painting and trimming business being carried on at the Fifteenth street and Warren avenue plant, as heretofore.

The motor is a four-cylinder Continental, 4 1-8 by 5 1-4, of L-head type, and with cylinders cast in block. It is suspended in the chassis at three points. It drives back through a 1 3-4-inch tubular shaft to the gearset bolted to the jackshaft. Substantial gears having a face width of 1 inch are used in the gearset, and afford three selective speeds.

The design is conventional throughout with the exception that there are no brakes placed on the jackshaft, both service and emergency sets being located on the rear wheels. By eliminating jackshaft brakes, any strain on the jackshaft and chains, due to stopping, is cut out.

Metropolitan S. A. E. to Meet Oct. 29

NEW YORK CITY, Oct. 21—The Metropolitan Section of the Society of Automobile Engineers will meet on October 29 at the Automobile Club of America, where Professor W. C. Marshall will present a paper on Dr. A. Riedler's work and his book on "The Scientific Determination of the Merits of Automobiles." Prominent engineers will give their opinions.

Find Lozier Assets $4,912,717.97

DETROIT, MICH., Oct. 19—The inventory taken by the Detroit Trust Co., receiver for the Lozier Motor Co., shows assets valued at $4,912,717.97 which are appraised at $2,069,-718.50 on the basis of a "going concern," while under "liquidating" circumstances the value would be $1,366,584.46. In this last named value the real estate, buildings, power house machinery and equipment of the plant in Detroit and the one in Plattsburg, N. Y., is not taken into consideration.

The total value of the liabilities is placed at $6,709,141.88 more than half of which, $3,494,700 is capital stock, $2,602,-668.11 unsecured claims, $241,054.17 secured liabilities and $370,736.63 contingent liabilities.

With the completion of the inventory of the Lozier Motor Co., by the receiver, the Detroit Trust Co., the results will be submitted to Judge Tuttle, of the United States District Court, who will decide upon the future course to be taken.

Prominent men in the automobile business were among the appraisers selected by the receiver to help it in making the inventory. Among these men were Henry M. Leland, president and general manager of the Cadillac Motor Car Co.; C. A. Pfeffer, treasurer of the Chalmers Motor Co.; G. H. Kleinert, factory manager of the Chevrolet Motor Co.; Richard E. Baus, assistant production manager of the Studebaker Corpn.

Receiver for Premier Motor Mfg. Co.

INDIANAPOLIS, IND., Oct. 19—A number of creditors of the Premier Motor Mfg. Co., Indianapolis, Ind., filed a petition in the United States court on Saturday, October 7, asking that a receiver be appointed and that the company be adjudged bankrupt. In the absence of Judge Albert B. Anderson, the matter was referred to Albert Rabb, referee in bankruptcy, who set November 2 as the time when the Premier company should appear and show cause why the action asked for, should not be taken. On Saturday Mr. Rabb appointed Frank E. Smith, formerly of the American Motors Co., receiver.

The petition is signed by three companies with small claims. They allege the company is insolvent and that while insolvent it preferred certain creditors.

In the Marion County Circuit Court Friday, October 15, Judge Charles Remster appointed the Fletcher Savings and Trust Co. and F. Barnickol, treasurer of the company, receivers for the Premier company on a suit brought by one company which claims there is due to it $1,691.75 for merchandise and that the Premier company is in danger of insolvency and that creditors are threatening to bring action.

The court authorized the receiver to borrow $10,000 and to continue the business for 10 days. At the expiration of that time, the court will determine what further action shall be taken toward continuing the business.

In the complaint, it is alleged that the Premier company has a total indebtedness of about $400,000, that there is outstanding $320,000 in preferred stock and $100,000 of common stock. It is further alleged that the book assets, which are in excess of actual value, are insufficient to discharge liabilities to the stockholders; that there is much indebtedness past due and no present means of discharging or caring for any part of this indebtedness.

The plaintiff asks that the receiver be authorized to complete cars under process of construction and to sell these and all completed cars on hand as soon as a reasonable price can be obtained for them.

In November, 1913, the capital stock of the Premier company was increased from $1,250,000 to $1,750,000, at which time a number of creditors were tendered new preferred stock in lieu of cash in settlement of their claims. The following week, a number of new men entered the directorate of the company, making the personnel of the board as follows: F. Barnickol, C. O. Baxter, A. L. Reeves, Clarence Stanley, H. O. Smith, Timanus J. Wilson and G. A. Weidely.

Firestone Convention Closes—Big Success

AKRON, O., Oct. 19—Over 250 representatives of the Firestone Tire & Rubber Co., this city, attended the sales conventions of that company on October 14 and 15. The attendance was so large that the conferences could not be held in the old Convention Hall, it being necessary to hold them in one of the partially finished additions to the Firestone factory.

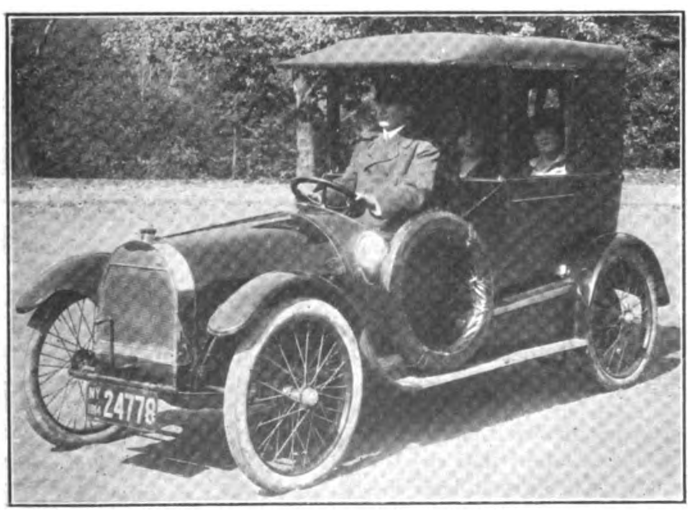
The company, at their recent annual meeting, announced a 78 per cent. increase in output over the previous fiscal year. All departments have been crowded to more than capacity in order to take care of this additional business and the new additions, now nearing completion, will add a total of 96,800 square feet to its floorspace.

The convention officially closed with the banquet at the Portage Hotel, but many of those in attendance remained until Saturday.

Twombly Taxicab Sells for $600

NEW YORK CITY, Oct. 21—Taxicab transportation at the rate of 20 cents per mile is promised by the Twombly Car Corp., Nutley, N. J., which has announced a taxicab to sell for $600. It is stated that within a few months a fleet of these vehicles will be operating in New York, the charge for the first mile being 25 cents and for each additional quarter, 5 cents. It is to carry two people. According to the terms of the contract, the purchaser of one of these cabs cannot charge more than 25 cents per mile.

The body is a landaulette type with the roof extending well over the driver's seat, the driver being located directly in the center of the vehicle. The wheelbase is 100 inches and the tread 44. The car weighs only 1,400 pounds. The motor is an L-head design with four cylinders 2.75 by 4 inches, and rated at 12 horsepower. It is water-cooled and lubricated by a combination splash and force-feed system. A three-speed sliding gearset is located on the rear axle; and drive from the motor is accomplished by means of a chain located on the left.



Twombly taxicab which buyers must operate at 25 cents per mile

900-Mile Race Planned—El Paso to San Diego

If Sanctioned, Contest Will Be Held in January or February

NEW YORK CITY, Oct. 16—Application for a sanction to hold a 900-mile Panama-California Exposition road race between El Paso, Tex., and San Diego, Cal., has been made to the Contest Board of the American Automobile Assn.

The San Diego Automobile Racing Assn., which guarantees to furnish a $10,000 purse for the contest, filed the application. It is planned to have the race start in El Paso some time during January or February.

This will be the longest automobile race ever run, barring the round-the-world race won by the Thomas car, and exceeds in distance the Paris-to-Berlin and to Madrid contests.

With the San Diego race added to the Grand Prize, Vanderbilt, Panama-Pacific, Los Angeles-Phoenix, El Paso-Phoenix and the Corona cup contests, the Pacific Coast will this year be the Mecca of automobile racing.

Classification of R-C-H Creditors Confirmed

DETROIT, MICH., Oct. 17—In the bankruptcy court an order was signed yesterday confirming the proposed classification of creditors of the defunct R-C-H Corp., as submitted by the trustee, the Security Trust Co.

According to this decision creditors with claims aggregating $1,365,610.01, who had signed an extension agreement October 25, 1912, will receive nothing whatever on their claims as the debts arising after that date will not be paid.

Referee in Bankruptcy Lee E. Joslyn has called a meeting of creditors for November 4, at which time a dividend of from 10 to 20 per cent. will be declared on the claims which accrued after October 25, 1912, and which amount to $275,773.72. The Trust company is preparing to disburse from $60,000 to $70,000 for these dividends.

Under the schedule submitted by the trustee as confirmed by the court, the deposits of agents aggregating $76,560.45 will be treated only as general claims and will receive about 10 per cent. in dividends.

Certain creditors who have filed objections to the classification will have their claims determined at a later date.

It is estimated that those creditors who sold goods to the defunct corporation after the extension agreement will receive about 65 per cent. of their claims.

The thousand creditors affected by the bankruptcy court order may appeal from this order any time up to October 31, 1914.

Disco Enters Electric Starter Field

DETROIT, MICH., Oct. 18—With a capital stock of $60,000 and an entirely new organization, the Disco Electric Starter Co., has just been organized succeeding the American Electric Starter Co., which itself had absorbed the old Disco company. The new concern's incorporators are Jacob and Henry J. Dornbus, of Grand Rapids, Mich., and Charles J. Carpenter of this city, while the officers are Jay Johnson, president; Charles J. Carpenter, vice-president and T. D. Murton, secretary-treasurer. Mansell Haskett, who has been with both of the former concerns is general manager of the new works. The company will manufacture a new electric starter at its plant on Jefferson avenue and Leib street.

Petition Filed Against Overman Co.

NEW YORK CITY, Oct. 20—A petition in bankruptcy was filed against the Overman Tire Co., Inc., with salesrooms at 1853 Broadway and factory at 250 West Fifty-fourth street by four creditors.

The company is a Delaware corporation incorporated in February, 1913, with a capital stock of $3,000,000. E. R. Perkins is president.

Judge Mayer appointed B. W. B. Brown receiver under a bond of $5,000 and authorized him to carry on business for 10 days. The attorneys for the creditors state that the liabilities are between $60,000 and $70,000 and assets are over $60,000.

A note for a large amount is about to mature and the company could not meet it.

New England — The Realm of the Automobile Tourist

(*Continued from page* 749)

eighty over a year ago. Pennsylvania held up well, Kentucky dropped five and Tennessee gained four. The figures follow:

Border Line Group

	1912	1913	1914
New York	209	220	300
Pennsylvania	78	80	81
West Virginia	0	1	0
Kentucky	4	9	4
Tennessee	6	5	9
Totals	297	315	394

The Far West group now has seven states to four a year ago, Arizona, Colorado and Oklahoma coming in. But there was a decline despite this fact, and it shows a loss of nine, as follows:

Far West Group

	1912	1913	1914
Texas	8	10	9
Kansas	1	9	4
Nebraska	4	3	0
California	7	4	1
Arizona	0	0	1
Colorado	2	0	1
Oklahoma	0	0	1
Totals	22	26	17

The foreign group shows a gain of seven, with Germany and Portugal being added this year to the list, an encouraging showing. Here are the figures:

Foreign Group

	1912	1913	1914
Canada	2	3	7
Puerto Rico	2	4	3
England	0	1	1
Germany	0	0	1
Portugal	0	0	1
Cuba	1	1	3
Honolulu	1	0	0
Brazil	1	0	0
Totals	7	9	16

Here are the recapitulated figures:

Electric Vehicle Convention Opens—European Development

(*Continued from page* 755)

mail work and early in 1914 thirty 2.5-ton Electro-Daimler wagons.

Paris Refuse Disposal

Paris has what is said to be the most elaborate system of household waste disposal in existence. About 2,600 tons are handled per day or 900,000 tons per annum. Before motor vehicles came into use 730 carts, 1,500 horses and 3,000 men were required to handle the work.

This spring a modern system of far-reaching effect was inaugurated. This contemplates the use of electric trucks and five large consuming plants as a substitute for horse wagon methods and the flooding of the Seine flats with the waste material. Two of the incinerators have been built; one at Ivry-Port and one at St. Ouen. Forty-eight electric carts are used at the former plant and forty at the latter.

Future Is Bright

The carts are charged in two garages built by the city of Paris in the immediate vicinity of the incinerators. They are at present owned and operated by a stock company which is paid a certain price per cart kilometer, the city of Paris having the right to purchase the carts outright in 4 or 5 years at an agreed price.

While the war must invariably hamper industry in many lands, I should say that, discounting the war, **the outlook for the electric vehicle in Europe is decidedly brighter than at any time in the last decade.** I have not gone into the development or use of vehicles in Spain, Switzerland or Italy. There are some electrics used even in Russia. Last spring plans were under way to build 1,200 light weight passenger electrics at one plant in England, an encouraging sign. The war will undoubtedly retard immediate construction of all types of electrics, but the conflict may help the cause of the storage battery vehicle in all the countries where horses and gasoline vehicles have been commandeered.

French Automobile Regulations Are Growing Stricter

(*Continued from page* 751)

ers were decidedly annoyed at this action on the part of the heads of the French and English tire industry and expressed their dissatisfaction so forcibly that at the end of a couple of weeks the English company resumed business on the original basis. The curious feature of the situation is that both these companies took advantage of the patriotic wave, announcing 'Business as Usual,' 'Follow the Flag,' 'Stand by the Old Country,' 'Support British and French industries,' etc.

"Practically our entire stock of tires, both at the factory and at the Paris stores, was requisitioned by the Government. These tires were left in our hands, but could not be sold to the public, the army having the right to call for them at a moment's notice and pay for them according to a pre-established tariff, which is practically the price paid by dealers. There was no interruption in the production of band tires for trucks, but practically all we produced was taken up by the army. The strict regulations under which we have existed for a couple of months have been somewhat relaxed of late. We have been able to begin, on a small scale, the production of pneumatic tires and also to offer some of our stock to the public. It is expected that within a few days arrangements will be completed whereby we can export to England, thereby supplying the European countries not involved in the war. We have continued to do a certain amount of business with those parts of France not occupied by the armies, but the difficulty here has been the lack of shipping facilities. We have never experienced any difficulties with regard to the supplies of raw rubber and fabric."

Although Mr. Lumsden is optimistic regarding the future, he has to admit that the Goodrich company, in common with others, will have to bear losses.

Factory Miscellany

WILLARD Battery Co.'s New Plant—The Willard Storage Battery Co., Cleveland, O., manufacturer of the LBA battery, states that ground for its new plant was broken on September 24, and that the work of construction will be pushed forward as rapidly as conditions will permit. Ten acres of ground was purchased on East 131st street, occupying numbers from 256 to 294. The plant will contain 6 acres of floor space, leaving ample land for further expansion. Ten buildings will comprise the plant under existing plans. All buildings will be of brick, of the latest approved and most up-to-date construction and equipped with sprinkler system throughout. The various buildings will be entirely separate, sufficiently isolated from each other to insure adequate protection from fire and to furnish the maximum of light and air. The offices of the company will be housed in a handsome administration building two stories in height. The accounting, cost and purchasing departments, with necessary private offices, will be located on the first floor. The second floor will be devoted to a series of private offices for executives and heads of departments, with ample provision for order and filing departments, drafting room, etc. In a separate building dining rooms will be provided and equipped for the use of office and factory employees, and noonday lunches will be furnished at nominal cost. Throughout the plant especial care will be given to sanitation and adequate up-to-date equipment of bath rooms, dressing rooms, lockers, etc., will be installed. A feature of the plant will be a complete hospital for the care of employees, which will be under the supervision of a physician regularly employed by the company. It is the intention of the company to have the administration and several other buildings under roof before snow flies, so that they may be ready for occupancy as soon as practical in the early spring. A switch track from the Belt Line Railway, which communicates with all railroads entering Cleveland, will extend the entire length of the plot in close proximity to the end of each building. On this switch there will be ample space for twenty-five freight cars, and suitable shipping and receiving platforms will be built.

Chester Rubber to Enlarge—The Chester Rubber Tire & Tube Co., Chester, W. Va., has purchased additional ground and will enlarge its plant.

Benford Co.'s Plant—Plans are being prepared for a factory, 40 by 110 feet, for the Benford Mfg. Co., Mount Vernon, N. Y., manufacturer of spark plugs.

Goodyear Subsidiary Building—The Killingly Mfg. Co., Williamsville, Conn., a subsidiary of the Goodyear Tire & Rubber Co., Akron, O., will build a factory which will be used for making cotton duck for automobile tires.

$100 for a Name—The W. H. McIntyre Co., Auburn, Ind., manufacturer of Imp cars, is offering $100 to the person who suggests the best name for its two new models, of two-passenger and four-passenger design, electrically started and lighted and listing between $400 and $600.

Standard Truck's New Plant—The Standard Motor Truck Co., of Warren, O., has purchased a portion of the plant of the Day-Ward Co. on North Park street, Warren, O., which is being remodeled for occupancy after November 1.

To Manufacture Enamel—The Won Kote Enamel Co. has been organized by Paul Fuchs, F. J. Wirtz and F. Ed. Spooner, with headquarters at 903 Free Press Building, Detroit, Mich., and a manufacturing plant in Ravenswood, Ill.

Tire Co. in Harrison—The Auto Tire & Thread Co. has leased a factory building at Cross and Fifth streets, Harrison, N. J., formerly occupied by the Greenfield Engine Co., and will establish a plant for the manufacture of its specialties.

Ware Plant in St. Paul—A plant for the manufacture of Ware motor trucks will be erected in St. Paul, Minn., by J. L. Ware, president of the company. The structure will be 200 by 90, reinforced steel and concrete construction, to cost $40,000.

Saxon Making Foreign Shipments—During the first 10 days of this month Saxon Motor Co., Detroit, Mich., has shipped cars to South America, British Guiana, the Philippines and Canada, and has received several inquiries from dealers in other countries.

Monroe Co. Acquires Wheel Plant—The Monroe Motor Co., Flint, Mich., has been incorporated with $250,000 capital stock to manufacture automobiles. R. F. Monroe, U. C. Durant and A. B. C. Hardy are among the incorporators. It has acquired the plant of the Imperial Wheel Co.

Henderson Plant and Parts Sold—Samuel L. Winternitz & Co., auctioneers of Chicago, on October 14 sold at public auction the plant, finished cars, material, parts and accessories, machinery, equipment and fixtures of the defunct Henderson Motor Car Co., Indianapolis. The sale was conducted in piece-meal.

Ahlberg Co. Opens Factory—The Ahlberg Bearing Co. has opened a factory and office in Los Angeles, Cal. This company specializes in regrinding annular ball bearings. J. W. West, formerly of Chicago, who has made his home in Los Angeles during the past year, will be associated with the company.

Oxford Plant Closed—The plant of the Oxford Motor Cars & Foundries, Ltd., Maisonneuve, Montreal, Que., has closed down for the present on account of the present war and the financial stringency. The company expects to resume business next spring. The Oxford 1915 models will be identical with the present ones.

Sub-Casing Plant Sold—The Fisher Mfg. Co., makers of the Fisher rim-grip sub-casing, has sold its entire Los Angeles plant and manufacturing rights to the Western Auto Sub Casing Co. The new company is headed by a group of capitalists of Seattle, Wash. M. S. Williams is the president of the new concern; A. T. Griffin, vice-president, and H. S. Nettleton, secretary and treasurer.

Page Windshield Co. Will Increase Force—The Page Woven Wire Fence Co., Adrian, Mich., which makes a specialty of windshields for Ford cars is now making from 300 to 400 a day and will soon have a total force of 150 men in its factory. In addition to the Ford windshields others are also manufactured.

Shaw Motor's New Plant—The Shaw Motor Co., Chicago, Ill., has decided to establish its plant in Sauk City, Wis., and has plans for a factory which will cost between $30,000 and $40,000 with machine and tool equipment. The building will be 60 by 108 feet in size, one story high, of fireproof construction, and equipped for the production of multiple cylinder gasoline engines.

May Buy G. M.'s Clyde Plant—Representatives from the East Palestine Tire & Rubber Co., East Palestine, O., recently visited the abandoned plant of the General Motors Company at Clyde, O., with a view of purchasing the plant and equipping it as a tire factory to be operated as a branch of the East Palestine concern. It is said that in case the purchase is made the plant will have a capacity of 500 tires daily.

Takes Over Michigan Spring Business—The General Spring & Wire Co., Detroit, Mich., has taken over the business of the Michigan Spring & Wire Co., 932 Mack avenue. The new company, which has a capital stock of $10,000, will make a specialty of wire springs for automobiles. J. H. Clark is president of the new concern; August Peterson, vice-president; C. L. Clark, secretary, and J. N. Reid, treasurer.

Williams Co.'s Plant in Vista—A. D. Williams, president of the Williams Tire Co., Glassport, Pa., announced recently that his company had acquired 10 acres of land on the Caleb Hamilton farm in Vista, 6 miles above McKeesport, on the Baltimore & Ohio Railroad. Work will begin within a few weeks on a new plant for the manufacture of tires, tubing and other rubber articles. The plant is expected to begin operation in the spring and will employ about 500 men and boys. The capital stock of the company has been increased from $5,000 to $300,000, with $60,000 of the new issue subscribed for, according to Mr. Williams.

Morton Truck's Big Order—The Morton Truck & Tractor Co., Harrisburg, Pa., according to an announcement of one of its officials, has just closed a contract with E. B. Van Atta & Co., of New York City, for 100 trucks of different sizes to be delivered within a year. The order totals about $300,000. Another order has been placed with a Buenos Ayres company for a large number of tractors, to be delivered from ten to twenty-five a month. The company recently purchased the new building of the Model Typewriter Co., on Nineteenth street, and is occupying this property. It is a three-story brick structure. The officers of the company are: S. F. Dunkle, president; J. V. Kuntze, vice-president; John Campbell, treasurer, and Walter Morton, secretary and manager.

The Week in  the Industry

Motor Men in New Roles

FARR Resigns from Knox—H. G. Farr has resigned as chief engineer of the Knox Motors Co., Springfield, Mass., and will open an office in that city as consulting engineer. Mr. Farr was a pioneer of the industry, having, in conjunction with Harry A. Knox, designed one of the first successful gasoline cars in America. He has been with the Knox company since it started.

Atkinson White Sales Manager—Robert Atkinson has been named sales manager of the Seattle, Wash., branch of the White Co., Cleveland, O.

Clapp Sales Manager—C. J. Clapp has been appointed sales manager of the Paige-Toledo Co., Toledo, O., distributer in northwestern Ohio for the Paige cars.

Bump Studebaker Manager—F. R. Bump has succeeded Hanson Robinson as manager of the Studebaker agency in New York City. Mr. Robinson recently resigned.

Denvir Joins Federal Truck—J. P. Denvir has resigned from the Gibney Tire Co., New York City, and has been appointed assistant sales manager of the Federal Motor Truck Co., also of that city.

Hane Goes to Portland—J. P. Hane, who has been connected with the Cadillac agency in Los Angeles, Cal., and in Boston, Mass., has gone to Portland, Me., to act as sales manager for the Cadillac agency.

Rand Manager—C. D. Rand, of the Simplex-Mercer Pacific Coast agency, has been appointed San Francisco branch manager for that company, and takes the position from which Bert Latham has recently resigned.

Howe Goes to Providence—F. E. W. Howe, for some years with Alvan T. Fuller in Boston selling Packard cars, has been promoted to be manager of the Providence agency for that make, which is controlled by Mr. Fuller.

Heintz Republic Tire Manager—C. W. Heintz, for the past 5 years connected with the sales department here of the Republic Rubber Co., was appointed manager of the Buffalo, N. Y., branch, B. F. Morris having resigned.

White District Sales Agent—An office with temporary salesrooms has been opened in the Murray Building, Grand Rapids, Mich., by the Wayne Auto Supply Co., Detroit. N. A. White has been appointed district sales agent.

Fisher Acting Secretary—Paul Fisher, of St. Louis, Mo., is at present acting as secretary of the St. Louis Automobile Manufacturers and Dealers' Assn., a position he will formally take next spring when Capt. R. E. Lee's term expires.

Wollaver Makes a Change—H. B. Wollaver, formerly connected with the sales department of the Chalmers and Stearns-Knight agencies, has been made manager of the service department of the Henley-Kimball Co., agent for the Hudson in Boston, Mass.

Boland Manager Jackson Branch—A factory branch has been opened in Council Bluffs, Ia., by the Jackson Automobile Co., Jackson, Mich. T. J. Boland, formerly with the Pioneer Implement Co. in this city, is manager of the branch, which will look after the business in certain sections cf Iowa, Nebraska and South Dakota.

Brownlee Purchases New Interests—The Weaver-Brownlee Co., Cleveland, O., succeeds the Weaver-Twelvetree Co., H. J. Twelvetree's interests having been purchased by J. A. Brownlee, who has been connected with the Philadelphia Pierce-Arrow agency for a number of years. He will have charge of all Pierce-Arrow pleasure car business, and becomes vice-president of this company.

Garage and Dealers' Field

Empire in Boston—The Empire Motor Sales Co. has established its own branch in Boston, Mass., securing salesrooms at 1002 Boylston street, near Massachusetts avenue.

Automobile Street Cars in Pendleton—The first real automobile street cars to be placed in service in Oregon have been installed at Pendleton, Ore., by the Pendleton Auto Street Car Co. G. K. Parker is at the head of this new transportation company. The cars have a seating capacity of forty people each.

Champion House Warming—About seventy automobile engineers and purchasing agents from Detroit and other automobile manufacturing companies were the guests at a house warming of the Champion Spark Plug Co., Toledo, O., October 10, to celebrate the recent amalgamation of the company with the Jeffery-Dewitt Co., Detroit.

New Departure Distributers—The New Departure Mfg. Co., Bristol, Conn., is establishing new distribution centers. The following additional distribution houses were established this past week: The Ahlberg Bearing Co., 325 West Pico street, Los Angeles, Cal.; The Chapin Co., Calgary, Alta., Canada; The Western Rubber & Supply Co., San Francisco, Cal.

The Automobile Calendar

Oct. 17-23	Los Angeles, Cal., Show, Shrine Auditorium.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 17-Nov. 1	Dallas, Tex., Show, State Fair Grounds, Dallas Automobile Dealers' Assn.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn's Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 23-24	Peoria, Ill., Illinois State Assn. of Garage Owners; Semi-Annual Convention.
Oct. 27	Indianapolis, Ind., Good Roads Day, Lincoln Highway.
Oct. 28	New York City, Commercial Tercentenary Celebration.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov. 2-6	Boston, Mass., Salon, Copley Plaza Hotel.
Nov. 3	Long Island A. C. Century Run.
Nov. 7-8-9	Los Angeles, Cal., Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 8-9	El Paso, Tex., El Paso-Phoenix Road Race, El Paso Auto Club.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 12	Phoenix, Ariz., Track Race, Maricopa Auto Club.
Nov. 17-18-19	Harrisburg, Pa., Second Conference of Pa. Industrial Welfare and Efficiency, State Capitol.
Nov. 26	Corona, Cal., Road Race, Corona Auto Assn.
Dec. 1-4	New York City, Annual Meeting of the American Society of Mechanical Engineers.
Dec. 12-19	Akron, O., Show, Akron Auto Show Co., O'Neill Bldg.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace
Jan. 3-10	Buenos-Aires, Argentina, Grand Prize of Argentina.
Jan. 9-16	Philadelphia Show.
Jan. 11-16	Buffalo, N. Y., Show, Broadway Auditorium, Automobile Club of America.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.
Jan. 30-Feb. 6	Minneapolis, Minn., Show, National Guard Armory, Minneapolis Automobile Trade Assn.
Feb.	Portland, Ore., Show, Portland Auto. Trade Assn.
Feb. 15-20	Omaha, Neb., Show, Auditorium, C. G. Powell.
Feb. 22	San Francisco, Cal., Vanderbilt Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Feb. 23-27	Syracuse, N. Y., Show, Syracuse Auto. Dealers' Assn.; H. T. Gardner, Mgr.
Mar. 6-13	Boston, Mass., Show, Mechanics Bldg., Boston Auto Dealers Assn. Boston Commercial Motor Veh. Assn.
Mar. 7	San Francisco, Cal., Panama-Pacific Exposition, Grand Prize Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Mar. 9-15	Des Moines, Ia., Show, C. G. Van Vliet.
Mar. 14	San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

Accessories for the Automobilist

ATTACHO Lamp — A trouble lamp which can be operated from any lighting circuit and fitted with a clamp which allows the lamp to be attached to any place convenient to the work, is manufactured by R. S. Mueller, 423 High avenue, S. E., Cleveland, O. It is shown in Fig. 1 attached to the top of a table. The jaw of the clamp has a 2⅛-inch opening. In addition there is a hook on the end of the clamp so that the lamp may be hung to anything suitable. The lamp may be swung through an arc of 180 degrees, as shown, and the shade may be rotated as desired so that the light may be directed just where it is wanted.

The use of an 8-candle power lamp is recommended. Twenty feet of cord are furnished. The price complete is $3 and without cord and plug $2. The postage is prepaid in either case.

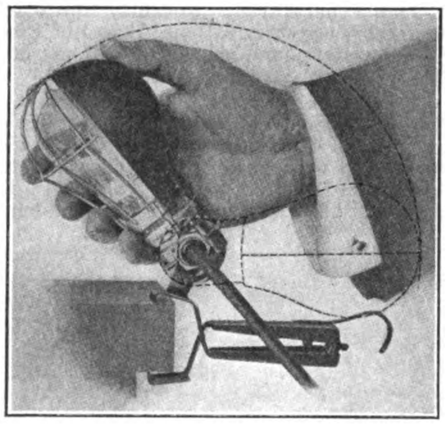

Fig. 1—Attacho trouble lamp

Stevens Pressure Gauge—A new type of pressure gauge for tires is announced by the Stevens Supply and Mfg. Co., Chicago, this new gauge being adjustable so as to make corrections for changes in spring tension. This gives the gauge the feature of reading accurately throughout its life, provided the tension of the spring is altered when required. Another feature is that the reading is not lost after the gauge is removed from the tire, allowing the pressure gauge to be used in the dark and then carried to a light to be read. The gauge with its end cap removed is shown in Fig. 2. The small part protruding pushes down the tire valve stem. The Stevens sells for $2.25.

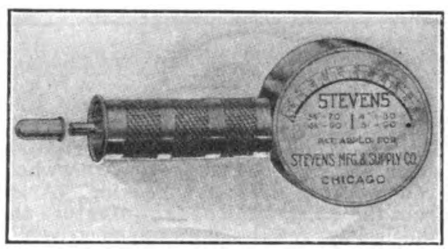

Fig. 2—Stevens tire pressure gauge

Breeze Two-Fuel Adapter — Claiming that the ordinary motor will give better results if a mixture of kerosene and gasoline is used instead of gasoline alone the Breeze Carbureter Co., Newark, N. J., is offering a device for controlling the flow of the two fuels to the vaporizing device. By the use of this system, which is controlled from the dash, either gasoline or kerosene or a mixture of the two in various proportions may be fed to the carbureter, or no fuel at all may be fed, allowing the motor to suck air. The last named feature is valuable when descending hills, in which event the motor may be made to act as a brake and cooled by the frequent changes of air. The Breeze device consists of a two-way valve, as shown in Fig. 3, and a regulating device on the dash controlling the valve openings by a wire. With this system it is possible to start the engine on gasoline and then, after sufficient heat has been generated and the motor can accommodate the heavier fuel, the kerosene is switched on, or part kerosene and part gasoline used. The entire outfit sells for $5.

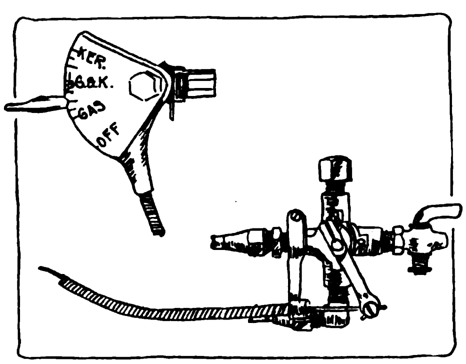

Fig. 3—Breeze two-fuel adapter

Weaver Garage Press—Garagemen will be interested in the Weaver press, which has a capacity of 20 tons, and performs such work as straightening shafts, pressing wheels on shafts, compressing springs, straightening frames, etc. This press is manufactured by the Weaver Manufacturing Co., Springfield, Ill., and is made of jointless channel steel. For light work, the 15-inch wheel, shown in Fig. 4 is sufficient to provide quick action, but for heavy work, a lever arrangement is provided which affords a leverage of about 1,500 to 1 and enables the maximum pressure of 20 tons to be exerted. The press sells for $48 complete with lever attachment.

Hupp-Yeats Worm Axle—The new Hupp-Yeats Electric Car Co., Detroit, Mich., has recently brought out a worm-driven axle for the cars of this make already in the hands of owners.

The application of the motor to rear axle housing has been worked out so that it is identical with the old construction; that is to say, the motor suspension is the same.

The motor shaft is attached to the worm shaft by a short coupling, and the motor head is bolted to the flange on the worm housing by the studs in present use on the motor head.

The new axle comes painted, with motor coupling ready to be applied to end of motor shaft and end of worm shaft, and with holes accurately drilled in worm housing to take the motor studs attached to motor end plate. The axle will be identical with axles in service with the exception that it will have a smaller housing to house the worm gear. The mechanical difficulties to make axles interchangeable have all been worked out so nicely that the new axle will go under the car in place of the old without any special adjustments and can be quickly and easily applied by the most ordinary mechanic or garage man.

The price of the new axle, taking old axle in exchange and delivered free of transportation charge at Detroit, is $200 net cash f.o.b. Detroit. This includes the motor shaft and worm shaft coupling.

Forest City Combination Holder—Another accessory for Ford cars, in the shape of a license pad and starting crank holder, is announced by the Forest City Electric Co., Cleveland, O. The holder is applied to the front of the car under the shackle bolt nuts. It serves to hold the starting crank handle in an upright position and also forms a support for the license plate. It sells for $1.

New Ford Coils—The Ford Motor Co. now is supplying new coil equipment for model T cars built previous to 1914. The new coils have tungsten instead of platinum points, and are claimed to retain their adjustment for a longer period. The Ford company claims more satisfactory service can be obtained with the new

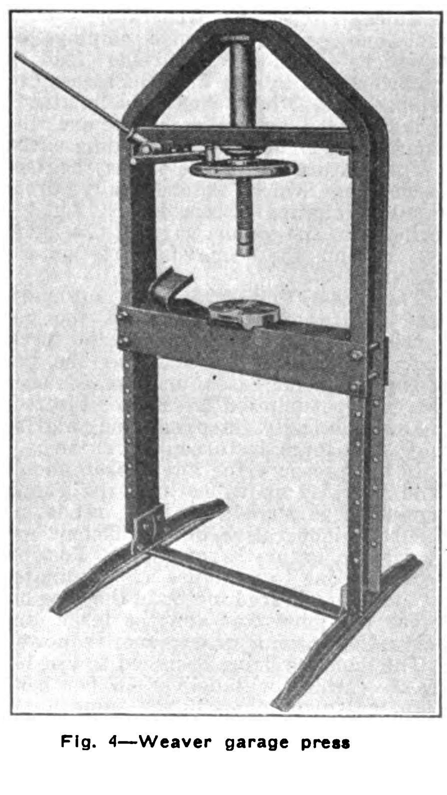

Fig. 4—Weaver garage press

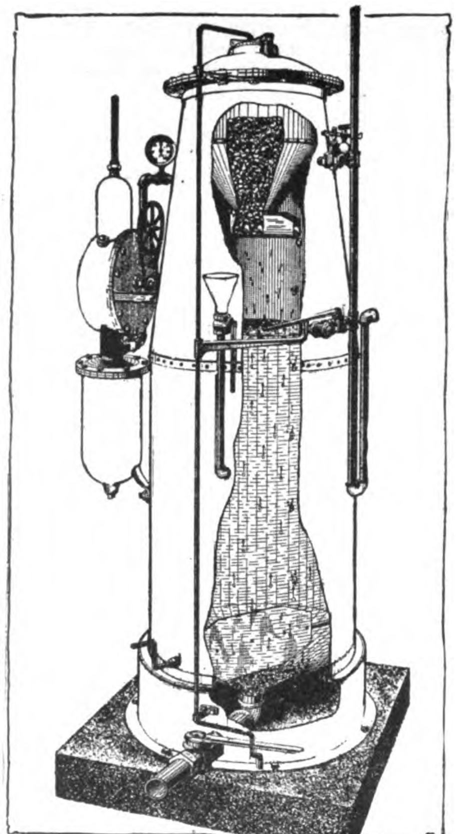

Fig. 5—Vulcan acetylene generator

coils than with the older ones. The price is $10 if the old coils are returned.

Edison Electric Vehicle Lamp—The Edison Lamp Works of the General Electric Co. has added a new Mazda tail lamp to its line of electric vehicle lamps. The new lamp is of 8 watts, 24 to 90 volts of the regular concentrated filament construction. It is of 1¼-inch diameter with a maximum over all length of 2¼ inches. It is fitted with either double or single contact bayonet candelabra base to operate in the standard tail light.

Vulcan Acetylene Generator—An acetylene generator which employs an ingenious method of carbide feed is manufactured by the Vulcan Process Co., Minneapolis, Minn., and Cincinnati, O. It is designed especially for the exacting demands of an autogenous welding outfit.

The feature of the device is the feed mechanism which automatically drops small briquettes of carbide ⅜ by 1¼ inches into the water, varying the quantity to suit the demands made on the gas supply.

The motor that drives this automatic feed utilizes the buoyancy of the gas passing from the generator to the torch, thus the feed is increased as the gas consumption increases, or lessened when the gas consumption lessens, or the feed is automatically stopped and started when the torch is turned off or on.

If the pressure for any reason should tend to raise above normal, the gas is conducted through a by-pass, rendering the feed inoperative until sufficient gas is used to lower the pressure. Possible accidents due to puncture are eliminated by locating the feed motor in the pipe between the generator and the torch, and using the passing gas as motive power.

The machine being designed to use 1¼ by ⅜ carbide will deliver 15 per cent. more acetylene than if the same quantity of screenings of carbide was used and better gas results from the carbide falling deep into the water before complete decomposition ensues, securing cooler generation under higher temperature than is possible with screenings which has a tendency to decompose near the surface, causing failure to give the gas the benefit of rising through a considerable volume of water, whereby it is washed and cooled.

The carbide chamber and feed mechanism are removable, thus opening the machine for complete inspection. The entire generator is protected by patents against careless manipulation by a locking device which prevents removing the cap for refilling or opening any valves, without following a definite safe routine.

This generator was recently approved and passed by the National Board of Fire Underwriters, and therefore will not increase insurance rate, it is stated.

New Cameron Wire Wheel for Fords—The Cameron Wire Wheel Co., Detroit, is making a new detachable Ford wire wheel, by use of which it is possible to make a change of tires on the road in 30 seconds, it is claimed. The wheel is held

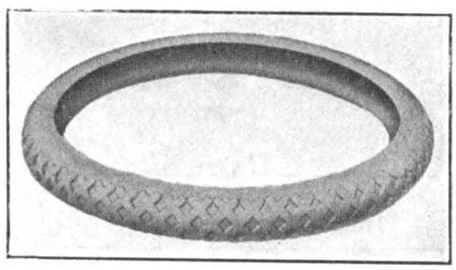

Fig. 6—Mohawk retread band

in place by an outside locking nut that can be removed with an ordinary wrench. Driving is done by large taper studs which are designed to prevent the wheel from wearing loose or squeaking. Aside from the quick tire changing feature the wheels improve the car's appearance. A set of five wheels and four inner hubs, complete with bearings, brake drums and nickeled hub caps, costs $35.

Thermoplax for Radiator Caps—A black composition known as Thermoplax is being marketed by the Cutler-Hammer Co., Milwaukee, as suitable material for radiator caps. It is said the material will withstand a temperature range from 30 to 600 degrees F. The substance is easily molded into shape around a metal insert.

Mohawk Retread Band—A semi-cured, endless band of rubber with a non-skid surface designed to be vulcanized over tires calling for retreading is announced by the Mohawk Rubber Co., Akron, O. This band cannot be applied except by vulcanization and requires the same heaters and tools that are necessary in applying a plain retread. The band is made in the following sizes: 30 by 3½, 32 by 3½, 32 by 4, 34 by 4, 34 by 4½ and 35 by 5, which takes care of practically all the standard diameters in use for in nearly every case one size, if stretched, will do for many. The band is cured in a mold and shaped so that it wraps closely to the tire carcass. The inside of the band has upon it a layer of pure gum which gives the vulcanizing cement a firm hold. The band is shown in Fig. 6.

Alemite Drill Stand—The Stromberg Motor Devices Co., 64 East Twenty-fifth street, Chicago, Ill., is distributing a handy device for holding tools. It consists of a die casting, Fig. 7, containing two circles of holes in which the drills are carried. The device is made in two sizes, both of which sell for $2. One is designed for drills 1 to 60 and the other for drills from 1/16 to ½ inch by sixty-fourths.

It is claimed that this drill stand will save much time and money wherever drills are used to any extent. The time spent in locating a drill from among a dozen small tools on a bench—or in finding the drill desired from an ordinary drill block or stand, or in walking back and forth from machine to bench to change drills—will soon pay for the drill stand.

The handle of the stand makes it easily portable and the drills are always accessible—a twist of the hand turns the stand until the number of the desired drill is brought to view.

Under each drill is the drill number in large, black figures and below these are the sizes of the drills in decimals. The drill stand is not only a container for these tools, but is also a gauge as well. The holes are so accurate that only the proper drill will fit.

S. & B. Tube—The S. & B. Mfg. Co., Worcester, Mass., is marketing the S. & B. tube, an ingenious device for carrying the operator's license and registration certificate. It comprises a compact, hollow cylinder, about the same length and weight as an ordinary key, and it is attached to the key ring. The capacity of the tube is such that it will accommodate the license or certificate, which is rolled up.

The device will appeal to motorists who frequently change their clothes and who might neglect to place their certificates in the new apparel. Being attached to the key ring, it is pointed out that one is less liable to forget it when changing. The S. & B. tube retails for 25 cents.

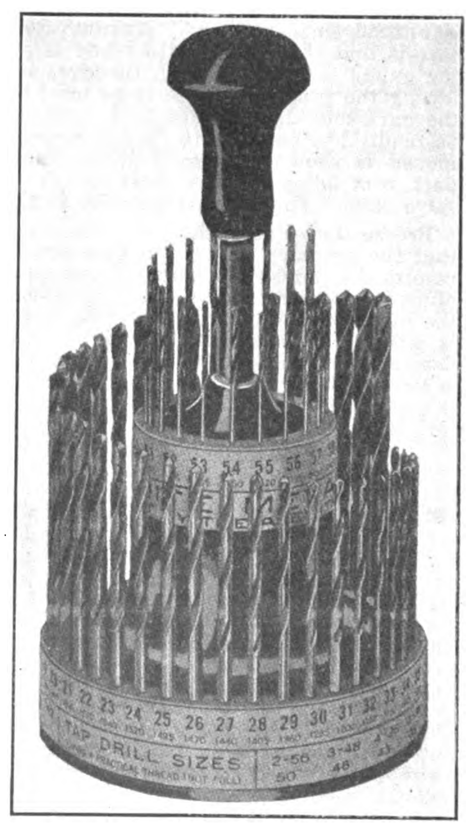

Fig. 7—Alemite drill stand, which is handy for carrying drills about the shop, etc.

The AUTOMOBILE

United States Has 1,735,369 Cars

Registration to October 1 Shows Gain of 203,503 Over Statistics Up to July

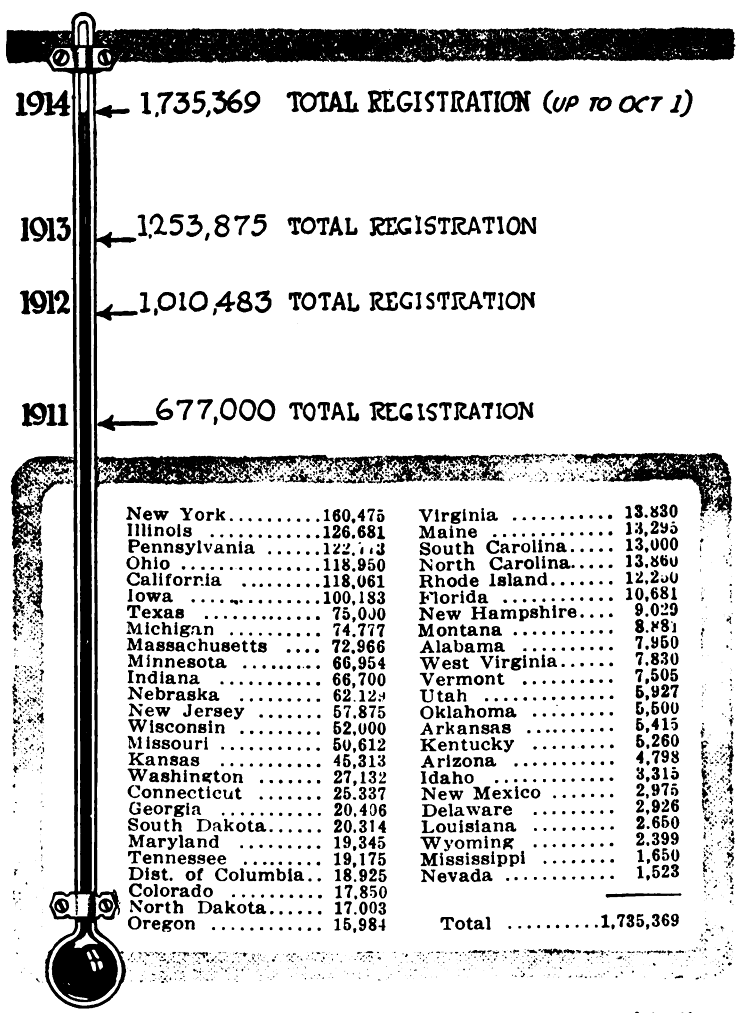
By Donald McLeod Lay

BEARING out the indications of the early part of the year automobile registrations for 1914 bid fair to eclipse all previous records, for the registration officials of the various states report increases in every instance save one, the total registration on October 1 being 1,735,369 after all duplicate registrations have been deducted.

These figures of course include both gasoline and electric vehicles as well as a large number of steam machines. In arriving at the total given all cases of duplicate registration due to the registration of non-residents in the various states and the re-registration of cars upon transfer of ownership are subtracted. Without allowing for this duplication the grand total of registrations is 1,758,253, the non-resident registration in the country totaling 7,332 while the re-registrations amount to 15,552, a total of 22,844.

On January 1, 1914, allowing for duplicate registrations, there were 1,253,875 cars and trucks in use in the United States. By July 1 there had been an increase of 294,485 over this figure, the total being 1,548,350. The increase in registration from July 1 to October 1 is 203,503, or practically two-thirds as much as the gain for the entire 6 months preceding July 1. It is evident that in spite of the talk of hard times and the effect of the European war upon business, the people of the United States are buying cars in great numbers just as they have been for the past decade. In fact the automobile industry has become one of the most important as well as one of the most spectacular in the country, so much so in fact that it formed the subject of a widely quoted address by William Livingstone, President of the Dime Savings Bank, Detroit, at the Annual Convention of the American Bankers' Assn. held at Richmond, Va., October 15.

The present standing of



New York	160,475	Virginia	13,830
Illinois	126,681	Maine	13,295
Pennsylvania	122,[illegible]	South Carolina	13,000
Ohio	118,950	North Carolina	13,860
California	118,061	Rhode Island	12,2[illegible]0
Iowa	100,183	Florida	10,681
Texas	75,000	New Hampshire	9,029
Michigan	74,777	Montana	8,881
Massachusetts	72,966	Alabama	7,950
Minnesota	66,954	West Virginia	7,830
Indiana	66,700	Vermont	7,505
Nebraska	62,129	Utah	5,927
New Jersey	57,875	Oklahoma	5,500
Wisconsin	52,000	Arkansas	5,415
Missouri	50,612	Kentucky	5,260
Kansas	45,313	Arizona	4,798
Washington	27,132	Idaho	3,315

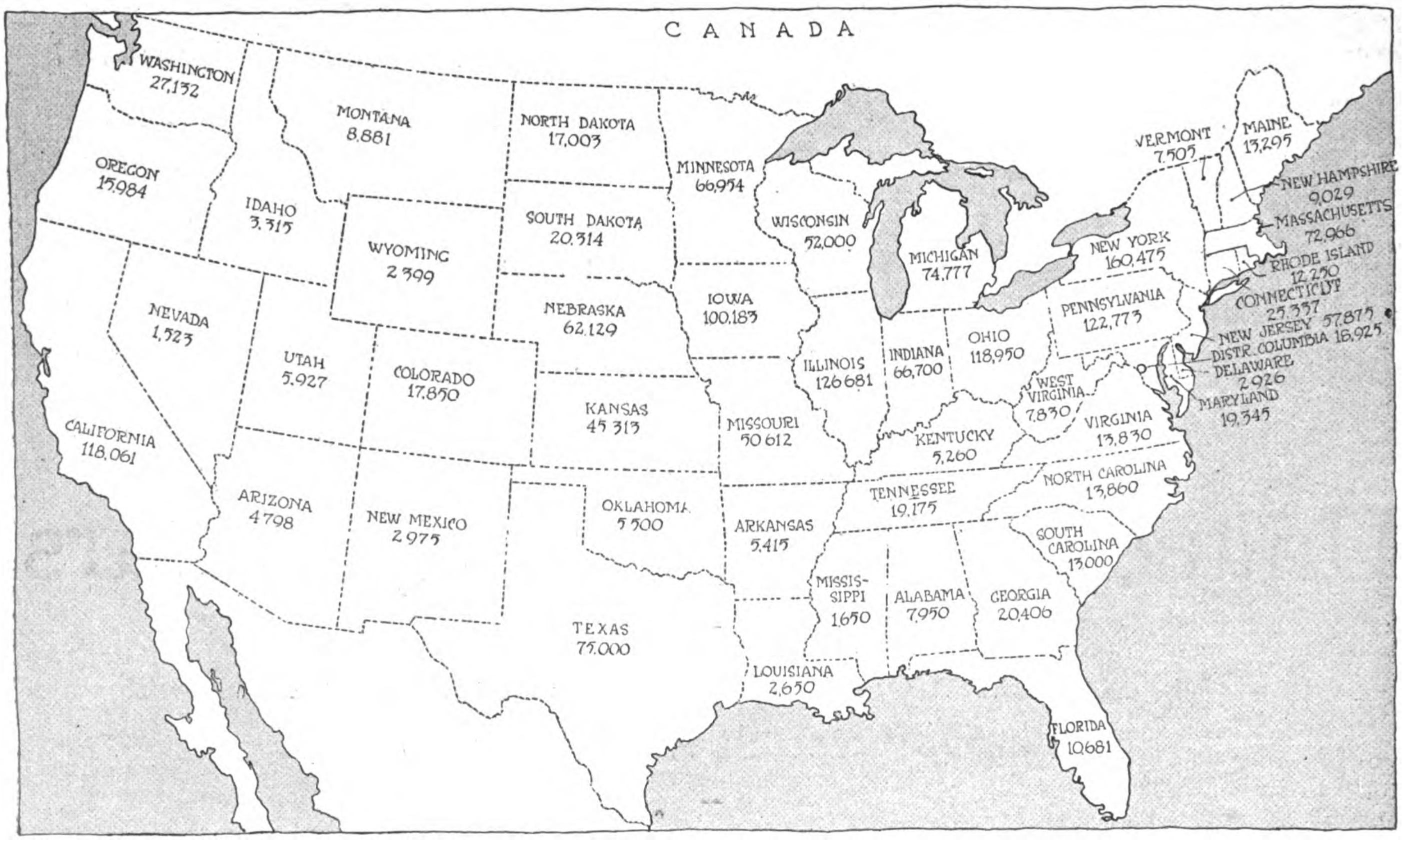
Tennessee	19,175	Mississippi	1,650
Dist. of Columbia	18,925	Nevada	1,523
Colorado	17,850		
North Dakota	17,003		
Oregon	15,984	Total	1,735,369

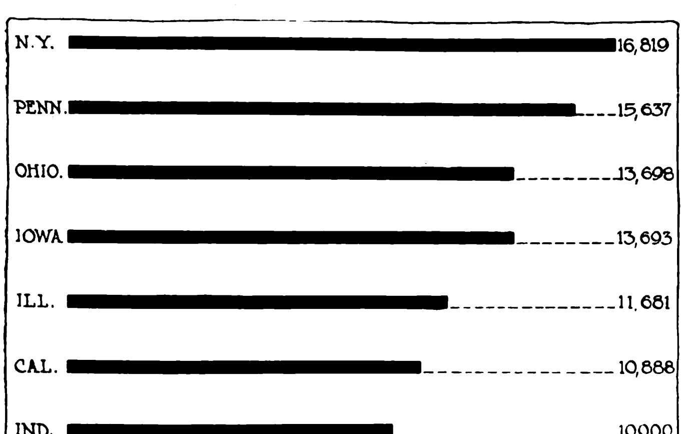
Registration to October 1, 1914, allowing for duplicate registration



Map showing actual registration of automobiles and motor trucks up to October 1, 1914, excluding duplicate registration

the states in respect to automobiles and motor trucks registered can be seen by referring to the tabulation on page 787 where they are arranged in order of magnitude of registration. It is greatly to be regretted that so few states have systematic, businesslike methods of keeping their registration records, as the failure to do so renders it impossible to tell the number of vehicles of various types and classes. The table on page 789 is an actual illustration of this, showing how few registration officials are really able to tell how many gasoline, electric and steam passenger cars and how many trucks there are in the state.

New York has taken a big leap forward in registration during the 3 months from July 1 to October 1, its total now being 160,475 after all duplicate registrations have been allowed for. This represents a gain of 16,819. Illinois is still in second place with 126,681, a gain of 11,681 for the 3 months. Third place is held by Pennsylvania with 122,773 or 15,637 more than on July 1. California has been ousted from fourth place by Ohio which now has 118,950 or 13,698



Seven states showed increases of 10,000 or over cars and trucks in the 3 months from July 1 to October 1

more than at the last showing. California's gain is 10,888 giving that state a total of 118,061. Iowa shows the phenomenal gain of 13,693, its registration being 100,183. Texas, Michigan, Massachusetts, Minnesota, Indiana, Nebraska and New Jersey retain their positions in order just as in July, their registrations ranging from 75,000 down to 57,875. Wisconsin has passed Missouri with a registration of 52,000 to Missouri's 50,612. The rest of the states are all below 50,000 ranging from Kansas with 45,313 down to Nevada with 1,523.

Many Changes Below 50,000

The order of the states with registrations below 50,000 is greatly changed since July 1, Washington having passed Connecticut with 27,132 as compared with the Nutmeg State's 25,337. South Dakota has passed Maryland, Tennessee and Colorado and farther down the list many other changes are to be seen.

There are five states with registrations between 50,000 and 20,000, these being Kansas, Washington, Connecticut, Georgia and South Dakota. The number between 20,000 and 10,000 comprises over twice as many states, the twelve being Maryland, Tennessee, District of Columbia, Colorado, North Dakota, Oregon, Virginia, Maine, South Carolina, North Carolina, Rhode Island and Florida. There are nine states with registrations between 10,000 and 5,000, these being New Hampshire, Montana, Alabama, West Virginia, Vermont, Utah, Oklahoma, Arkansas and Kentucky. The balance, comprising Arizona, Idaho, New Mexico, Delaware, Louisiana, Wyoming, Mississippi and Nevada, have less than 5,000 cars and trucks each.

Order of Gains Made

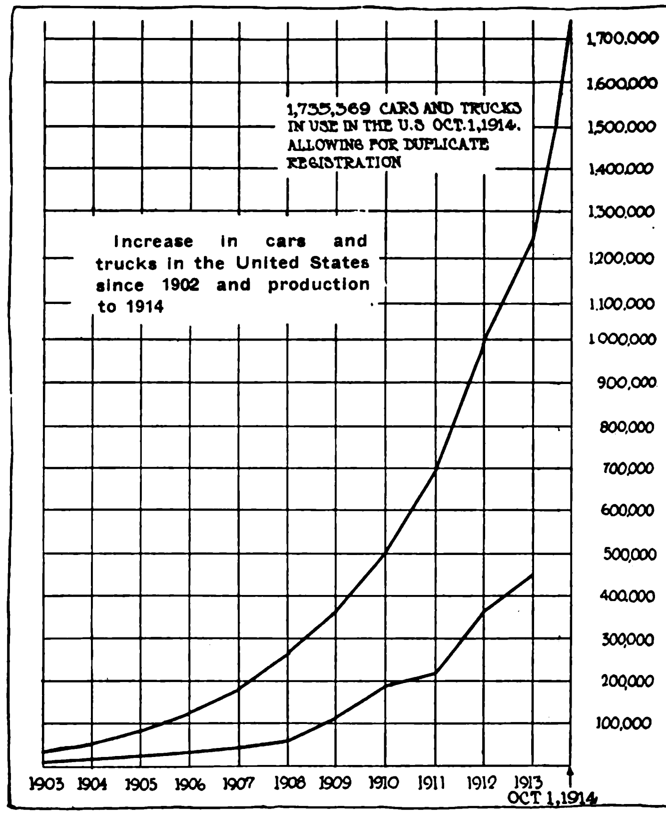
The order of standing in regard to the number of cars and trucks gained by each of the seven states leading in this respect is illustrated in the chart at the left of this page. New York leads with an increase of 16,819 with Pennsylvania second, its gain being 15,637. Ohio is third with an increase

of 13,698 and Iowa fourth with 13,693. Illinois shows 11,681 more registrations than on July 1 giving it fifth place while California with 10,888 takes precedence over Indiana with 10,000. The other states showing gains of over 5,000 registrations for the 3 months are not illustrated but stand as follows. Michigan is eighth with 9,260, Massachusetts, ninth with 9,129, and Missouri tenth with 7,889. New Jersey has 7,568, Wisconsin 7,000, Washington 6,496, Nebraska 6,140, Montana 5,700, Kansas 5,424 and Texas 5,000.

The Law Situation

One welcome improvement in the automobile law situation is the prospective adoption of an automobile law requiring registration of automobiles and trucks by Louisiana. This is one of the few states which has not as yet had a law requiring state registration. South Carolina and Texas are other states where registration is local. The District of Columbia, Florida and Texas require registration but once in contrast to the yearly registration required by the other states, excepting Minnesota, which provides for the registration of its motor vehicles once every 3 years. The Michigan and Mississippi laws are still under the ban of the courts, having been held unconstitutional some time ago. It is considered likely that the Michigan statute will be amended and re-adopted.

In the twenty-one states where statistics were available on the subject there were a total of 310,377 chauffeurs registered. There are six states in which the registration of chauffeurs is not required. The total of the fees received for the first 9 months of 1914 is $8,817,654.



Automobile Registration in Each State in the Union up to October 1, 1914, with Duplicate Registrations

State or Territory	Total Registration	New Registration	Registration up to July 1, 1914	Gasoline Passenger Cars in Use	Gasoline Commercial Cars in Use	Electric Passenger Cars in Use	Electric Commercial Cars in Use	Non-Resident Registration*	Re-Registered**	Chauffeurs Registered	Total Fees	Remarks

Foreign Trade Is Not Foreign Selling But Barter

Other Countries Also Have Products to Market, Speakers Tell Manufacturers' Export Assn.—Investment Needed and Sane Methods—South America Bankrupt—Wants Money, Not Goods

SEVERAL thoughts upon which little emphasis has been laid to date in the movement for the development of our foreign trade were brought out at the fifth annual convention of the American Manufacturers' Export Assn., which was held at the Hotel Biltmore, New York City, last Thursday. One of the most important of these, which it would seem has been overlooked almost entirely, is that the development of our foreign commerce means, not foreign selling, but barter or exchange; that is, we cannot expect to ship our products to foreign countries and expect cash in return. These countries also have products which they must market.

South America Bankrupt

One of the speakers called attention to the fact that the South American countries are practically bankrupt and want our money, not our goods, while the point was also brought out that the investment of American capital in foreign fields is an indispensable adjunct to our commercial development abroad. Another excellent thought was that business is business the world over; that is, our business men, manufacturers and merchants should proceed about foreign business exactly as they do in transactions at home. Sane methods are needed, because foreign business is the same as domestic, only more difficult.

Merchant Marine Needed

That we need a merchant marine and that the Government should aid American shipbuilding by every means in its power and that officials should help our merchants instead of criticising them were sentiments dwelt upon by several of the speakers. An interesting fact brought out in one of the papers was that the United States has no class of men definitely trained for foreign work. In European countries men make this their vocation and are trained for it, learning foreign languages, currency systems and other things especially serviceable in this work. Two points were emphasized, the men must be adventurous and should not be held down to inadequate expense requirements, nor should they be harrassed by petty bookkeeping in this respect.

A strong hint was made in one of the papers that unless foreign trade is developed by the Government and our merchants, the domestic situation, instead of improving will soon become worse as the country becomes overstocked with native products. No that there are inadequate transportation facilities, for there are plenty of ships to be had, but exporters often hesitate to send out a laden ship in the fear of seizure by belligerent warships.

In all the agitation for extended export trade an important factor which has apparently been entirely neglected is the opening of the Panama Canal which has brought New York, Boston, Philadelphia and the rest of the Atlantic seaboard much closer to the ports of Hong Kong, Shanghai, Melbourne, Sydney, etc. In other words, we, and not Europe, are at the geographical and commercial center of the world.

James A. Farrell, president of the United States Steel Corp., said in part:

"Among the current economic fallacies is that with the present elimination of several of the manufacturing countries of Europe as sources of supply, the neutral consuming markets of the world must look to the United States for their requirements.

Neutrals May Need Help

"Bankers have learned that credit is an international commodity, and producers, whether engaged in farming or manufacturing, are now conscious of the fact that it requires an exchange of commodities between countries to maintain equilibrium of gold exchange. It is apparent that even a neutral nation cannot materially profit when a world-wide contraction exists of the mechanism of credit and the cost of foreign exchange. The problems at present confronting the export and import trade of the United States are largely due to the inability of the foreign buyers to finance transactions on a credit basis, due to straightened financial conditions in many export markets.

"At present there is no lack of shipping facilities, as there are more ships than cargoes to all parts of the world. Our trade is not halted through lack of transportation, but we should analyze this apparent security. The greater part of our oversea commerce is still being carried in foreign ships, and is, therefore, vulnerable to the hazards of war. Up to the present seventy-seven foreign-built vessels, aggregating 275,000 tons, have been transferred to American register, a comparatively small number when it is considered that upward of 2,500,000 of foreign flag tonnage is owned by Americans; but many more vessels would doubtless be transferred to the American flag if prudent revision of our navigation laws were made.

The Federal Reserve Act

"The Federal reserve act has been described as designed to make credit available to every man with energy and assets, and it is to be hoped that this will be true of the foreign aspect of our banking also. It remains to be seen how far the Federal Reserve Board will permit national banks, with their definite domestic responsibilities, to engage, through their foreign branches, in the diversified enterprises by which European banks, organized solely for foreign business, seek to aid the foreign trade of their nations.

"Except for the early dislocation of trade caused by the outbreak of hostilities, Great Britain has, despite the war, continued her foreign trade with little interruption, largely because of the effective emergency measures promptly adopted by the British Government; whereas, we seem to be in an unfortunate position, in that the Federal reserve system, which promises so much for the future, has not as yet been established. Nevertheless, it should be impressed upon our bankers, as well as upon our merchants and manufacturers, that, unless some steps are taken to insure uninterrupted continuance and development of our foreign trade, there will be an unfavorable effect upon our domestic situation.

"Many countries are now turning to the United States for funds. Future opportunities in foreign markets for our manufactures may be seriously lessened unless investment develops."

Herbert R. Eldredge, vice-president of

the National City Bank, said that it is not at all probable that we will have an American merchant marine worthy of the name for many years and only when Congress passes an act placing our ships on an equality in both the cost of operation and the cost of construction with those of our foreign competitors. He told of the plans of the National City Bank to establish branches in South America, and asserted that while these branches would undoubtedly help our exporters in the future efforts to gain trade in those markets, the bank officials realized that they had many obstacles and probably some losses and inconveniences to suffer at the outset. Mr. Eldredge warmly praised the Federal reserve act for its probable beneficial effect upon the development of our foreign commerce, but declared that it must be further amended before it completes its basic task of enabling our bankers to overcome many of the obstacles in the path for many years.

Alba B. Johnson, newly elected president of the association, touched upon the necessity for some form of Government aid for our shipbuilding industry, subsidies or bounties, or otherwise, by which we may hope to meet and overcome the handicap which the foreign shipbuilder and operator now holds of being capable to build and operate ships at a cost of from 40 to 50 and in some instances as much as 60 per cent. below the cost to our American interests.

Defends Our Exporters

William Harris Douglass, of the export commission house of Arkell & Douglass, strongly defended the manufacturers against the many criticisms directed at them during recent years, and more particularly since the war in Europe began, for their alleged lack of efficiency in their efforts to gain greater portions of the world's foreign commerce.

"We have heard more rot about South American trade from every conceivable source," Mr. Douglass asserted, "in the last 60 days than 50 years of trading can hope to overcome. The truth about South America is that she is now bankrupt. I was talking with a prominent banking and trade leader from Brazil only a few days ago, and he very frankly told me that all that South America wants from us just now is our money. I asked him if they did not want our goods, and he said, 'No.' What they want more than our goods is money and plenty of time to pay.

"We must go slowly with South America. Things must be made better down there if our bankers could bring themselves to the point of advancing between $250,000,000 and $500,000,000 to the Latin-American countries, for which they might very easily take over as security national bonds which are backed by the wonderful national and natural resources of the nations down there.

"I resent the criticism heaped upon the American manufacturers for their past efforts in developing export trade. We have done our best, and I resent the criticism simply because we have not seized in a moment the entire export trade of the world. I have traveled the path of progress made by our manufacturers in blazing the way for our expanding foreign commerce for 32 years, during which time, despite the fact that very little help has been given by the Government, we have succeeded in planting a very solid foundation.

Win Trade Despite Handicaps

"It is only 15 years ago that our first steamer went to South America. What are our transportation facilities today and what has the Government done to foster those facilities? Not one passenger boat, but miserable tramp steamers with which to carry our goods to those lands to the south of us. I don't see any prospect of changing that condition. England, on the other hand, has long years ago established freight and passenger lines to every colony she possessed. Let us put the blame where it rests—on the United States Government.

"The Federal Government should not only say that we now have the authority under the law to establish the long-needed foreign branch banks with which we might be able to finance our own obligations and collect our own debts from South America in the course of trading with those countries, but it should make the banks in this country establish the needed branches and if they won't the Government should take some action itself to establish such banking facilities. We also want a real international policy which will insure to us a reasonable open door to every nation of the globe."

Sane Methods Needed

Edward Ewing Pratt, the newly appointed chief of the Bureau of Foreign and Domestic Commerce, Washington, D. C., in an address on The Foreign Trade Situation, made a plea for sane business methods on the part of our exporters in going after increased trade in foreign fields. Mr. Pratt declared that if our manufacturers and exporters will only put into force in foreign fields the same methods as they have been using for years so successfully in the domestic fields they will realize the greatest benefits from their efforts.

"The only difference in essentials between foreign trade and domestic trade is that the foreign proposition is a little more difficult. We are confronted with a great opportunity. The belligerent countries of Europe, which have supplied 42.2 per cent. of the world's exports are not prepared to continue to do so. Yes, it is time to call for caution, but it is always time for that, for caution is one element in business policy. We must not be over-cautious, however.

"Let us get clearly in mind that 'foreign trade' is not 'foreign selling.' Foreign trade is trade, it is exchange. We cannot always sell, we must buy. This is particularly true of our trade with South America. Nor can we afford to make the mistake of supposing that the military orders from Europe indicate any real or permanent demand for American goods. Foreign trade is not a temporary situation, it is a permanent matter.

"Do you realize that the Panama Canal has brought New York, Boston, Philadelphia and the rest of the Atlantic seaboard much closer to the ports of Hong Kong, Shanghai, Melbourne, Sidney, etc., than London, Liverpool and Hamburg now are? In other words, those cities once had the advantage of distance, we have it today. The inference must be clear, we and not Europe are at the geographical and commercial center of the world. The world is our market. Let's get into it."

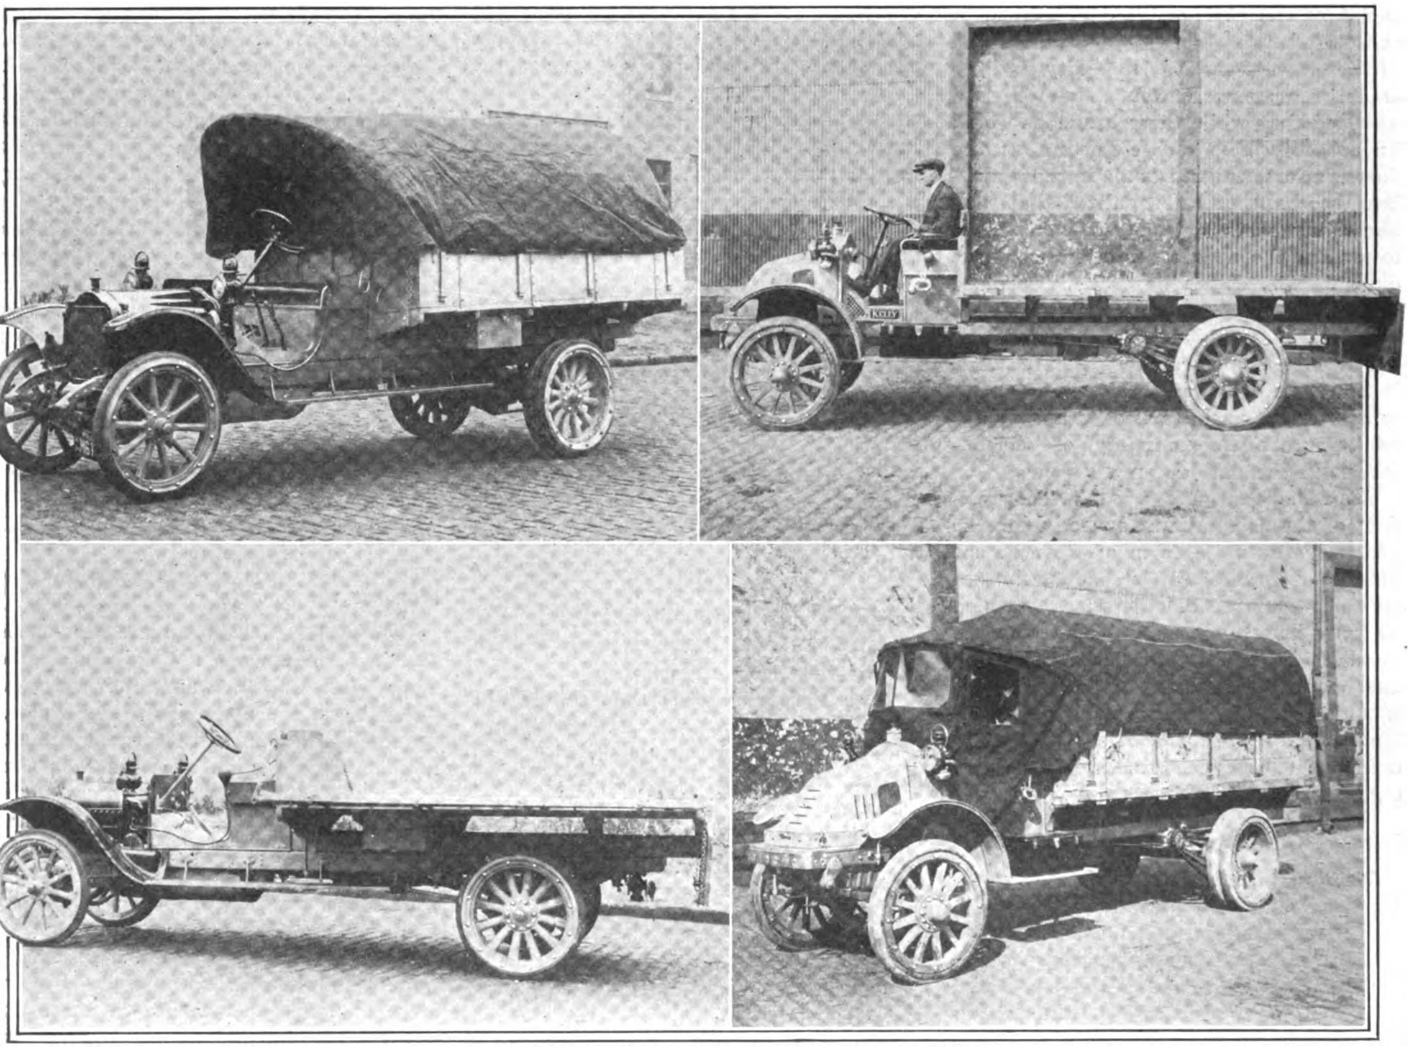
Men for the Work

George H. Richards, manager of the foreign department of the Remington Typewriter Co., in a forcible paper on: "The Personal Factor in Foreign Sales," dwelt at length upon the urgent demand and need for an adequate and efficient force of young American men, who might be capable of going into foreign markets of the world as selling representatives of our exporters.

"The personal factor in invading new markets has thus far not been emphasized," Mr. Richards said. "It is the human and sociological as opposed to abstract commercialism. If we narrow it down it becomes largely a matter of obtaining the proper men, especially young men, in the United States to undertake the work necessary to get our goods from our factories into the hands of our customers in the fields we seek to enter. The fact is that the United States never has had and has not today a class of young men from which to draw for foreign service similar to that to be found among our international competitors. The demand, however, is urgent. The promising candidate must be a man with much the spirit of the pioneer. He must be adventurous. He must be practically footloose. Duty must supersede all other considerations."

Mr. Richards urged that our exporters in selecting such foreign sales agents should not be parsimonious in allowing them sufficient money to cover elaborate social expenses as well as strictly business expenditures. The manufacturers, he added, must realize that traveling abroad is an expensive proposition, the agent's mission being ambassadorial, and his expenses are in proportion.

American Trucks to Play Part in War



Some of the 2-ton truck types purchased by the belligerent European nations. At the upper left is shown a White fitted with tarpaulin top, while below it is the same model with flat open body. At the upper right is a Kelly-Springfield with the same flat type of body and at the lower right is another Kelly-Springfield equipped with tarpaulin top

NEW YORK CITY, Oct. 28—Although reports have been prolific concerning large sales of motor trucks to the belligerent countries of Europe, sales have not aggregated one-third the amount reported. Rumors of concerns in America having orders for 9,000 trucks have been afloat for some time, but to date not more than 3,000 have actually been sold, in fact the total falls a little below this figure. This is a great export business, particularly for a line that has not figured prominently in the export column.

France Buys 1,740

One of the greatest sales was that made to the French government by five concerns, namely, White, Packard, Kelly, Pierce, and Jeffery, a total of 1,740 trucks, all of which have to be delivered by the first of the year. Of this total the sales were divided as follows: White 600; Packard, 450; Kelly 340; Pierce-Arrow 300; and Jeffery 50. These are practically all 2-ton types with the exception of Jeffery which are 1 1-2-ton. The Packard group is divided between 2- and 3-ton models.

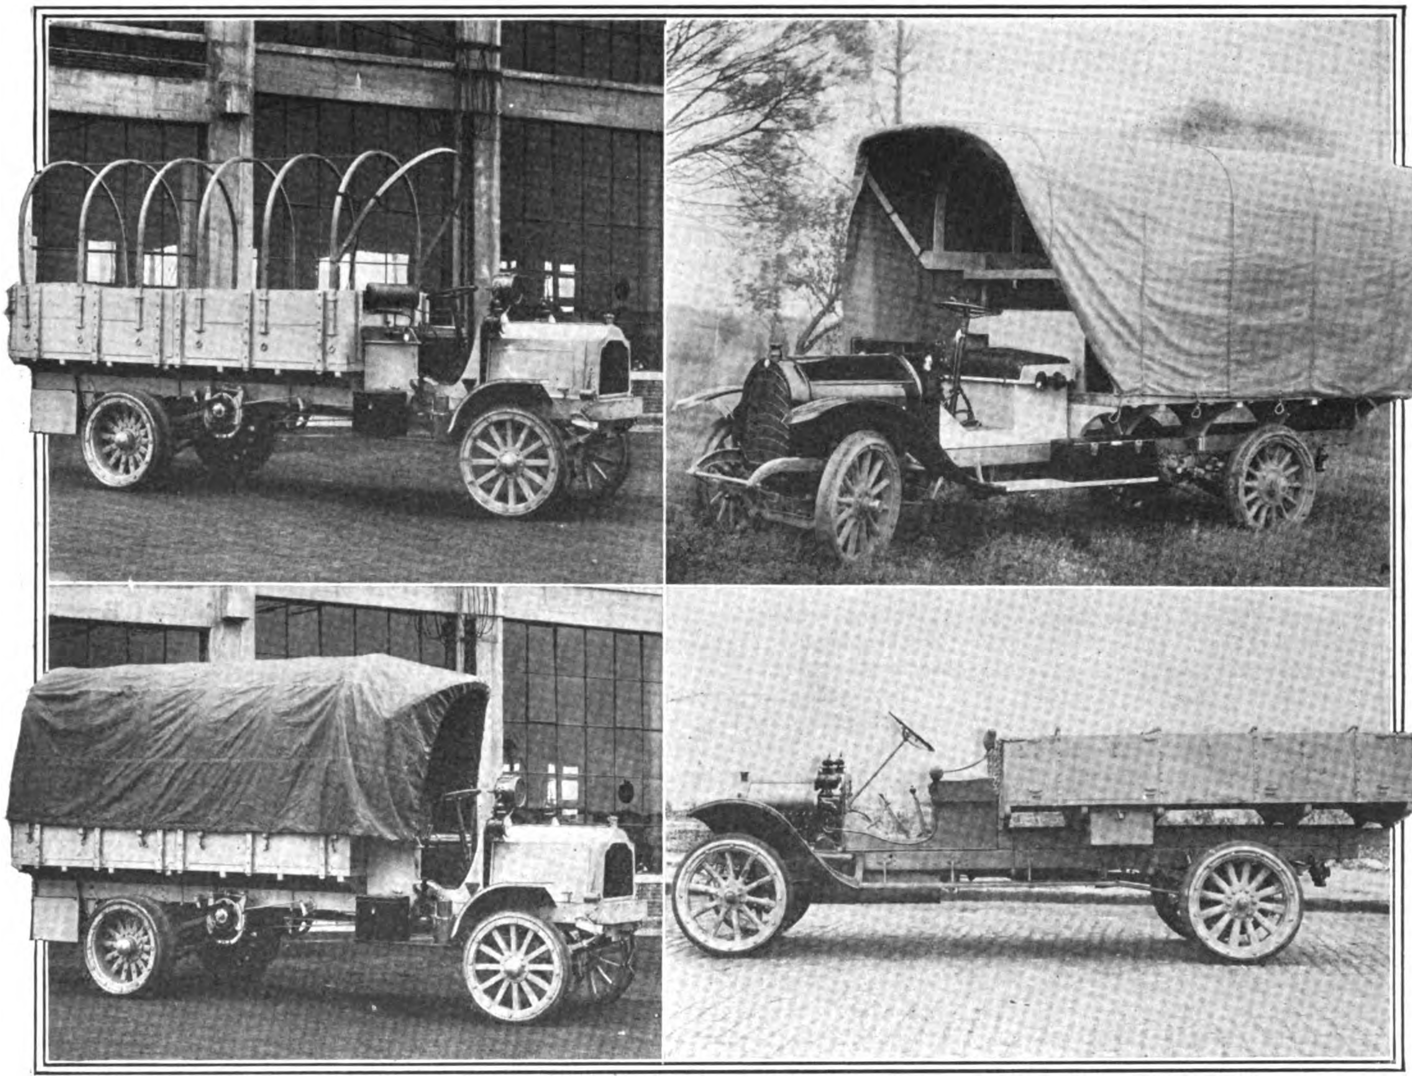
The illustrations on these pages show the conventional types of army body that has been fitted on all of these vehicles. These bodies are good examples of flexibility in that the two sides and tail-board are hinged to swing downwards. The sides are provided with chains to hold them in a horizontal position to make loading and unloading easy.

These bodies can either be used with or without the tarpaulin top. As shown in the Packard illustration these tops are supported by a series of removable metal bows roughly semi-circle in shape and fitting into brackets in the sides of the body. Over these bows the tarpaulin is stretched and secured giving an appearance not unlike the Prairie Schooner of by-gone days.

The Russian Body

The bodies on the White are what are known as the Russian design including the latest improvements. The platform of the body is not horizontal but standing in the rear of the vehicle and looking towards it the floor bows down in the center giving it an arc shape instead of a flat one. This is done in order that the loads carried press toward the center thus avoiding any tendency for loads to tumble off at the sides. On the other bodies the standard French army wagon job is fitted. These have the flat load platform and the hinged

—Several Shipments Already Made



The Packard shown at the upper left gives an idea of the body construction used with the tarpaulin top, the view just below showing the tarpaulin mounted. At the upper right is one of the Jeffery trucks fitted with a tarpaulin top of design similar to that employed on the other vehicle. At the lower right is a White with open box body

sides and tail-board, together with the metal bows for the tarpaulins.

On the Whites, which are the regular 2-ton model, with motor 3 3-4 by 5 1-8, the wheelbase is 145 1-2 inches and tires are 3 1-2-inch solids all around with duals in rear. The load-carrying platform measures 9 feet 6 inches long and 6 feet wide.

The Jeffery's are the standard 1 1-2-ton chassis with 110-inch wheelbase and block motor with cylinders 3 3-4 by 5 1-4. On the other models the standard chassis equipment regularly used is employed.

Other Sales

In addition to these French sales there have been several other shipments to belligerent and non-belligerent countries. Packard sold 198 to the Russian government, these being of 2-, 3- and 5-ton capacities. The Garford company disposed of approximately 142 to the same source and White sold some. Kissel has been making sales to the Greek government, totalling, according to reports, 100 vehicles. The Knox company has sold some few tractors to Greece.

There was a shipment of approximately 150 motor vehicles with the first Canadian contingent, and these included such makes as, Kelly, White, Packard, Peerless, Autocar, Jeffery and Russell. Many other sales have been reported but it is impossible at this time to definitely confirm them.

Many to Study Car Construction in Milwaukee

MILWAUKEE, WIS., Oct. 26—Hundreds of Milwaukee business men of standing have enrolled in the new course in motor car operation and repair established by the university extension division of the University of Wisconsin at the Milwaukee branch. The course is in charge of LeRoy Roberts, Cornell, '07, and is based, it is stated, on the fact that practically all of the accidents nowadays are caused by the ignorance of owners relative to caring for and driving their cars. Motor troubles uncared for and road laws neglected probably are the two greatest causes of accidents, and the new course, consisting of fifteen evening sessions during the coming winter will not only include instruction in repair and care of the car, but in road laws and driving.

"Seeing Ourselves As Others See Us"

English Engineers Analyze Their Industry in War Atmosphere and Make Recommendations—More Research Needed—Germany Has Led in This Work—Opportunity for America to Supply Raw Materials That Belgium Has Supplied

LONDON, ENG., Oct. 15—That it takes a war to stir up the Britisher patriotically, as well as industrially, is well illustrated by the activity of the Institution of Automobile Engineers, the British automobile engineering organization, as was shown by a recent meeting, when L. H. Pomeroy, a member of the council, presented a lengthy paper entitled, "Automobile Engineering in the War."

Mr. Pomeroy talks with characteristic John Bull frankness in his analysis of the automobile industry as brought about by the present war, condemning the policy of British manufacturers in one sentence and praising the policy of German and Belgian makers in the next.

Germany's Research Work

In speaking of the necessity for systematic research work in the automobile industry, he pays Germany a compliment when he says, "For anything like a systematic series of experiments on the automobile, its efficiency and effectiveness, we have to turn to Germany."

In another sentence he deplores certain inefficiencies in the British manufacturer and shows to what an extent Britain has had to draw on Continental countries for raw materials and parts for assembling.

Compliments Belgium

He pays a compliment to Belgium when, referring to a recent visit of the members of the Institution of Automobile Engineers to Belgian factories in which stampings were manufactured, he says: "Those who participated in the official visit to Belgium cannot fail to have been impressed with the scientific methods of stamping seen there, and, further, the unremitting care with which the product is checked, the elaborate research work which has directed the choice of the material used for the various purposes, its heat treatment, and the investigation of its physical and chemical characteristics."

Mr. Pomeroy brings out many facts which show the possibility of American concerns profiting by the fact that several of the Continental sources of supply have been practically eliminated because of the war. In this connection he says: "There are few in this country who produce a motor vehicle entirely from raw material. Quite 50 per cent. of the material is wholly or partly furnished by firms who specialize in the various lines of manufacture, such as pressed steel frames, radiators, wheels, springs, carbureters, ball bearings, tires, magnetos, bevel and worm gears, etc."

There are many of these parts that the English maker has to secure from abroad, particularly steel castings for truck wheels and other forms of such castings.

Free Research Department

In a very cosmopolitan manner Mr. Pomeroy suggests that a great opportunity presents itself for the English maker to resurrect himself in not a few regards an endeavor to produce on a price basis that will enable him to compete with Germany, Belgium and France. He believes that what is most needed is a committee of scientific experts to consider the question of conducting researches for manufacturers, free of charge, so far as these researches are of general interest and benefit.

Mr. Pomeroy's address in part follows:

The Address

Before considering the broad essentials to economical production, it is well to remember that this country has an enviable reputation for producing high-quality goods of all kinds. It is, in fact, in the position of a tradesman who has built up a business by supplying a first-class article at a moderate price, and in so doing has created a goodwill far too valuable to be thrown away by the emulation of any get-rich-quick methods which are not based upon the intrinsic lasting qualities and general honesty of the article supplied. Great Britain, in spite of foreign claims, is a land of culture, and because of this, demands a certain exclusiveness of product which is against quantity production on anything like the American scale.

To Follow Natural Lines

For this reason the author thinks that the automobile industry must be content to develop upon the natural lines it has followed here since its inception.

Its commercial importance must be based upon a definite superiority of design and execution attained through a constant attitude of healthy discontentedness with things as they are. It is this mental attitude which has maintained certain of our industries, notably steel making and ship building, at a level above competition, and if steadfastly followed out will raise the automobile industry to the same level.

There are in this country few firms, if any, who produce a motor vehicle completely and entirely from raw material. Quite 50 per cent. of the material composing a motor car is supplied wholly or partly finished by firms who specialize in the various lines concerned.

FOR INSTANCE, PRESSED STEEL FRAMES, RADIATORS, WHEELS, SPRINGS, CARBURETERS, BALL BEARINGS, TIRES, MAGNETOS, SPARKING PLUGS, BEVEL AND WORM GEARS, DETAIL FITTINGS SUCH AS INSTRUMENTS, GREASE CUPS, UNIONS, AND IN SOME CASES IMPORTANT UNITS SUCH AS ENGINES, GEAR BOXES, AXLES, ETC., ARE AMONG THE PARTS BOUGHT IN A FINISHED CONDITION READY FOR ASSEMBLING.

The real raw material of the chassis maker is made up of bar steel, stampings, malleable steel, iron, aluminum, bronze and brass castings, tubing, etc. A large part of the trade in the above commodities has been in the hands of Germany and foreign trade rivals, and it is of interest to discuss the principles underlying the successful production of some of the many individual items which are of supreme importance in motor car manufacture. After all, the basis of production is an ample supply of raw material and an ample choice of the sources of such supply. The elimination of Continental sources of supply has brought home to many of us how dependent we were upon them, and, further, how poorly some of our British suppliers compare with those on the Continent. The comparison is still more unfavorable to the British supplier when considered in the light of quality for price.

English Products

To come to articles directly within the compass of the British suppliers, the author would exemplify the following:

Light stampings of alloy and mild steel for parts subject to shock and alternating stress in which correct heat treatment is a sine quâ non.

Heavy stampings, such as back axle casings, front axles, flywheels, crankshafts, brake drums, tapered steel tubes.

Steel castings, particularly road wheels for commercial vehicles, back axle casings and other large castings where very thin sections are desired.

Pressed steel parts, such as brake drums, back axle casings, frames, torque members, step irons, etc.

High-tension steel tubes and thin plates.

Electrical insulating materials suitable for moulded forms, and departing from chassis requirements a little, the author would mention the demand for machine tools for special purposes.

In discussing the difficulties arising from obtaining parts such as those mentioned, the author is speaking from the point of view of a chassis manufacturer, who is anxious to obtain adequate supplies. It is obvious that there will be an influx into the ranks of material suppliers during the next year or two of firms whose previous experience has been outside the automobile industry, and it is to these who are unfamiliar with the very exacting requirements of the said industry that many of these remarks are addressed. To commence with stampings. One of the first difficulties that arises is a financial one, namely, that of payment for dies; this often forms a heavy item of expenditure, which prevents the adoption of stampings, and it would seem a poor policy on the part of stampers to emphasize this charge, as they so often do. Stamping or drop forging is an old industry in this country, but there seems to be room for considerable improvement in the methods of stamping.

There are many stampings which we cannot obtain here. Those members who participated in the official visit to Belgium in the summer cannot fail to have been impressed with the scientific methods of stamping seen there, and, further, the unremitting care with which the product is checked, the elaborate research work which has directed the choice of the material used for various purposes, its heat treatment, and the investigation of its physical and chemical characteristics. The number of firms in Great Britain so equipped is relatively small and usually confined to departments.

Criticize English Stamping

THE CHIEF COMPLAINTS AGAINST BRITISH STAMPERS IS, FIRST, A LACK OF KNOWLEDGE OF THE PHYSICAL CHARACTERISTICS OF THE MATERIAL THEY ARE STAMPING; SECOND, THE TENDENCY TO DISPENSE WITH PRELIMINARY HAND FORGING OF PARTS LIKE CONNECTING RODS, AND TO OVERHEAT THE METAL TO OBTAIN EASY WORKING AND QUICK PRODUCTION; THIRD, A LACK OF APPRECIATION OF HOW CLOSELY TO ITS DESIRED SHAPE A STAMPING CAN BE MADE, AND CONSEQUENT NON-UNIFORMITY OF PRODUCT; AND FOURTH, A COMPLETE DISREGARD, IN ALL BUT A VERY FEW FIRMS, OF THE MANIFEST ADVANTAGES OF HEAT TREATMENT AFTER STAMPING IN ALL CASES, AND ITS ABSOLUTE NECESSITY IN MANY.

Poor Heat Treatment

Last, but far from least, in the general consideration of the desirable qualities of stampings, is that of correct heat treatment. In this connection British firms are deplorably behind those on the Continent. The virtues of heat treatment have been as widely published as any information on a technical subject could be. The enormous increase of resistance to impact and fatigue through it must be known to the stamping trade if only from the demands of automobile manufacturers, and even now very little is done. The stamper will say he *can* heat treat if you require; he will not say that he *will* whether you ask for it or not.

There is a field which has been much less exploited than this and which is equally important, namely, heavy stampings, such as fly wheels, large hubs, back axle casings, and the like. In many cases these are now made as castings, and are, as such, perfectly satisfactory from the designer's point of view. But there are other points of view than that of the designer. The present epoch is that of the automatic machine tool, and for its successful use consistency of material is a *sine quâ non.* Until the makers of castings approach this ideal to a greater degree than they do at present, the qualities of stampings in respect of easy machining and consistency of texture make them an easy first for popularity among works managers whose susceptibility to irritation when an expensive forming tool or special tap is fractured through an occasional hard casting is well known. The large quantities which allow of the successful application of automatic machines are those which justify the expenditure on dies. The fact remains, however, that if all castings could be relied upon for uniformity of softness they would hold the field, first because of the fact that they can be made in intricate forms, secondly that the amount of material to be removed for a given object is usually less. For instance, a hub made as a stamping will weigh twice as much as a corresponding casting, and the difference in weight has to be removed by machining. It does not seem impossible to one who is not an expert in stamping problems to hope that by a suitable series of dies much thinner sections of metal could be stamped than are at present produced.

Need Steel Castings

When the field for the supply of malleable iron and steel castings is surveyed we again become painfully aware of our deficiencies. The modern steel casting is an electric furnace product, and these furnaces were first exploited on the Continent owing to the abundance of cheap electricity, and the solution of the metallurgical problems involved.

IT IS TO-DAY A MATTER OF DIFFICULTY TO OBTAIN STEEL CASTINGS SUITABLE FOR AUTOMOBILE WORK IN THIS COUNTRY, REGARDLESS ALTOGETHER OF PRICE. IN PARTICULAR STEEL ROAD WHEELS ARE PRACTICALLY UNOBTAINABLE.

The production of a cast wheel in any metal is a matter of difficulty owing to the contraction stresses induced by unequal cooling, and the difficulty is probably greater in casting soft steel than in any other metal. Yet these difficulties have been met and completely overcome abroad with consequent loss of business to this country and its paralysis in this respect at the moment.

The same remarks apply to back axle castings, brake drums, etc.

The author can remember no instance when discussing steel castings that hard things were not said of them. Such firms as make successful steel castings are mainly engaged on very heavy work. It is probably again due to the fact that the automobile has been beneath the notice of our leading works until a year or two ago that more progress has not been made.

THERE IS A BIG HEALTHY MARKET FOR GOOD STEEL CASTINGS THAT SHALL BE SOUND, SOFT AND EASILY MACHINED, THE LAST TWO QUALITIES NOT BEING IDENTICAL.

Again, we are up against the bugbear of minimum thickness. The author has tried to get castings of exhaust manifolds 1-8 inch in thickness and failed. He then put the thickness up to 3-16 inch, and got sound castings; but, unfortunately, upon sawing them up he found the thickness to vary from 3-16 inch to 5-16 inch, mostly the latter. The importance of the subject is more far-reaching than is at first imagined, and the expenditure of a lot of time and money on the production of very thin castings, say down to 3-32 inch thick, would be well rewarded.

Finish of Castings

The external finish of steel castings is also another weak spot. This may not sound important, but it is one of the things that, other things being equal, decide the destination of contracts. Malleable iron certainly scores in this respect. When dealing with steel and malleable castings from the same pattern the two metals are quite easily identified. The chief complaints in regard to malleable castings are occasional hard batches and perpetual delay in delivery. It is necessary to be a prophet to deal with malleable iron successfully. Its physical characteristics are, however, very good. There seems no reason why it should not be a good material for road wheels and compete with steel castings all around.

In considering the possibilities of trade expansion due to the elimination of foreign competition, cylinder castings, ball bearings and electrical apparatus come to mind. The first two are already in a healthy state, and the equals of anything turned out anywhere, but electrical apparatus, insulating material, high tension cable and sparking plugs, to say nothing of the magneto, are all open to criticism.

The author has passed a high-tension current through a piece of red fiber alleged insulating material 18 inches long; he has cut the insulating material off the outside of high-tension cable with more ease than a garden hose could be cut; he has experimented with countless brands of sparking plugs that pre-ignited in less than three minutes in an engine running at 2,000 revolutions per minute, and in his opinion the state of affairs is bad in which such materials can be offered for sale, much less used. The British manufacturer of these articles can gain infinitely by delivering the real goods, and now is the time for him to get going. It is idle to talk of foreign competition when that competition is allowed to become a monopoly.

Research Work Needed

For anything like a systematic series of experiments on the automobile, its efficiency and effectiveness, we have to turn to Germany. Such scientific work as has been done here on engines has only been done by men of undisputed authority in the world of physical science, but out of touch with the industry, working on obsolete engines and obtaining results of about as much practical use as the Technical College tests of its steam engine.

We want information not for its use in teaching students to measure accurately, though that is of first importance, but for the suggestion of improvements and for indicating departures in design that shall place the British industry at the head of the world's automobile producers.

The author would suggest that a committee be formed consisting of scientific experts and practical men to consider the question of conducting researches for manufacturers free of charge, so far as these researches are of general interest and benefit.

Economy in Research

If to it be added a series of experiments co-relating the heat discharge of a radiator with the velocity of cooling water through the tubes and the air velocity past them, we should have data for fixing radiator sizes which would be of great commercial value. From experiments made by the author he is satisfied that a radiator of about one-third the size of that now ordinarily fitted would be capable of properly cooling the engine. But before this can be done with safetv. it is necessary to have experimental data covering all likely conditions in use. An ordinary honeycomb radiator for, say, a 183-cubic inch engine costs roughly $50. If the radiator surface could be halved the price would fall at least 25 per cent. On an output of 1,000 chassis per year this is a saving of $12,500. Yet no one seems to have the resources and enterprise to try and make that saving. The author thinks that this sufficiently illustrates his point that research should be directed towards the saving of money.

Still dealing with matters relating to the engine, the carbureter comes to mind. The claims of carbureter makers are monotonous in their uniformity of suggested perfection. The author feels sure that well-directed research into the effect of varying shapes of induction pipes, of the application of heat at the right spots and of true vaporization would result in the establishment of fundamental data to which carbureter makers could add their various mechanical devices at their own sweet will.

The bearing pressures and speeds of ordinary engineering practice are already exceeded in many gasoline engines, but there is every indication that still further reduction in size is possible, due to the rapidly rotating and reciprocating nature of the load in automobile engines.

Gearbox Research

Turning to the chassis, our opportunities increase. The author is informed on good authority that the Mercedes Grand Prix racer this year used a fourteen-tooth bevel pinion in the rear axle drive. If this can be done in the back axle, it can be done in the gearbox. A fourteen-tooth pinion is usually looked upon as a mechanical compromise owing to interference, unless the involute angle is very steep. But if a fourteen-tooth pinion can be made to run quietly without introducing other ill effects an important practical result follows. In a pleasure car, for instance, the relation between the fourth and the first speed is usually about 4:1, *i.e.*, a car geared to 3:1 on top is usually about 12:1 on first. Using a 14-tooth first reduction pinion the wheel gearing with it would have twenty-eight teeth, and at the other end of the box the ratio would be reversed, giving the 4:1 reduction; this refers to boxes with direct drive on top. If six-pitch teeth be used, this means a shaft center distance of 3 1-2 inches, which is decidedly less than current practice.

Compared with 4 1-2-inch centers, we have a saving in a four-speed box of forty-eight teeth per box, and a consequent considerable saving in weight due to smaller diameter stampings and reduced external dimensions of the whole gear-box. The only point which needs settling is whether a fourteen-tooth pinion can be made to run quietly.

It is an axiom that no design is good which cannot survive a liberal dose of bad workmanship. On this criterion gear-box design is bad indeed. The author knows of no manufacturer who is not troubled with the noise made by gear-boxes, and further, there seems no easy method of obtaining silence combined with durability.

If an engine be considered whose torque is constant up to, say, 5,000 revolutions per minute, and giving, say, 100 horsepower at that speed, driving a rear axle with a gear loss varying as the square of the speed, the available horsepower transmitted to the back axle would be, if the gear loss at 1,000 revolutions per minute were 10 per cent.:

at 1,000 revs. per minute....	20	—	2	= 18
2,000 " " "	40	—	8	= 32
3,000 " " "	60	—	18	= 42
4,000 " " "	80	—	32	= 48
5,000 " " "	100	—	50	= 50

These figures are, of course, extremes, and chosen to illustrate the point under discussion. For years automobile engineers have considered an automobile as a machine whose efficiency curve is a straight line. If this is not the case, and there is ample evidence to refute it, there is the important and far-reaching consequence mentioned which may materially affect the trend of design. The few instances chosen to indicate the possibilities of properly directed research work only approach the fringe of the subject.

All this may appear visionary, but it is the means whereby Germany has become the commercial rival she was, and will be again when the disturbance caused by the war has passed away. If Germany can then produce better articles than those made by any other country she will sell them, and if these next few years are allowed to pass without a strenuous effort on the part of our industries to place themselves in a position in which we can compete on equal terms, our opportunity will have been wasted.

From the pure design point of view the commercial vehicle has not yet attained much more than the stage of reasonable reliability, regardless of weight, engine power possibilities and economy. But there are signs that the commercial chassis designers are taking an interest in these latter, and in these directions the pleasure chassis manufacturers' experience should stand in good stead.

The battle for the high efficiency commercial chassis will doubtless follow on the lines of that in the pleasure-car industry, and the author can see no reason why the result should not be the same.

Already many firms are building both commercial and pleasure vehicles, and this policy will probably become more widespread during the immediate future while the industry as a whole is steadying itself. But sooner or later the *status quo ante bellum* will be restored, and it will be interesting to see how the automobile industry has used its opportunity.

Largest Crane Mounted on Peerless Chassis

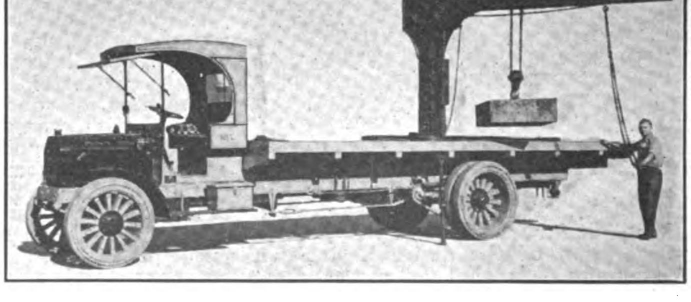
A TRAFFIC problem in the garbage department of the city of Detroit has been met by the use of a special Peerless 6-ton truck equipped with the largest crane that ever has been installed upon a motor truck. This crane will lift 2 1-2 tons onto the truck. Most crane experts have heretofore contended that a 1-ton crane was the largest that any truck could carry.

The garbage of the city of Detroit is carried on open coal cars to the plants of the Detroit Reduction Co. outside of the city. There are only a few substations at which the cars can be loaded for property owners in the vicinity object very strenuously to them and in many cases have forced the abandonment of newly opened stations.

This makes a long haul to the substation unavoidable. It was found impracticable to use motor trucks for the actual collections of garbage because the great frequency of the stops made it require as long a time to load a ton of garbage upon the truck as upon a wagon. Yet when horse wagons were used exclusively the long haul with the empty or fully loaded wagon would often take from two to three hours. The wagons in many cases were able to make only one trip a day.

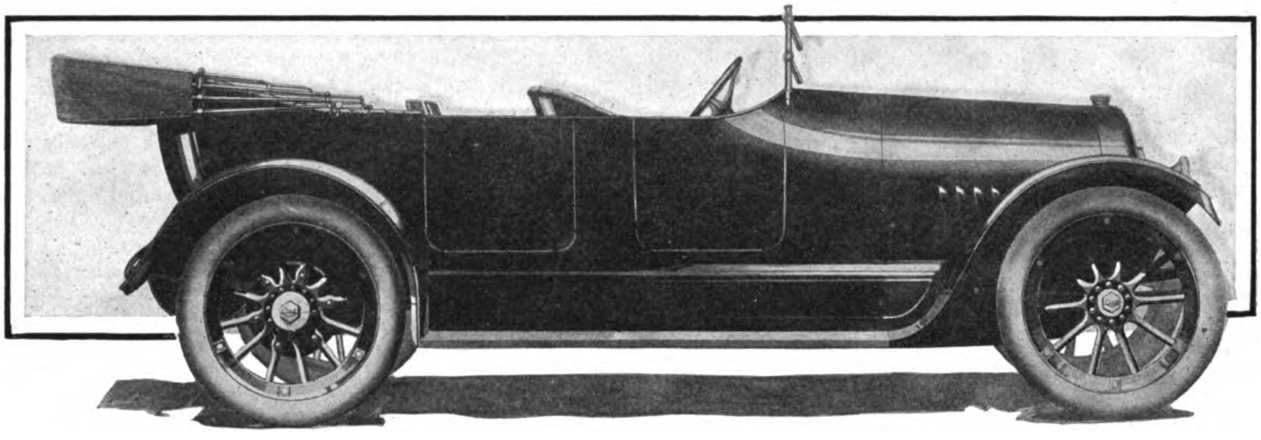
Jack Knight, superintendent of the Garbage and Street Cleaning Department solved this problem by the purchase of the special Peerless 6-ton truck. Garbage wagons from the different sections of the city are met on the way to the substation and their 2-ton loads are lifted off onto the truck by the crane. An empty box is hoisted from the truck to the wagon to be refilled. One wagon now collects two loads in the time that was formerly required to collect one.

In the case of the breakdown of a garbage wagon on the streets the truck picks up the load and removes it at once avoiding the very undesirable condition created when it has to be shoveled from one wagon to another.



6-ton Peerless truck fitted with crane for Detroit Garbage Department

New Four-Cylinder Cole for $1,485



Four-cylinder Cole touring car listing at $1,485 with 29-horsepower motor and streamline body

A FOUR-CYLINDER Cole listing at $1,485, or nearly $200 less than any previous four-cylinder made by the Cole Motor Car Co., Indianapolis, Ind., is one more example of the greater attention that is being given to fours of a medium size for next season.

This model uses the Northway unit motor, clutch and gearbox, the motor having cylinders 4.25 by 5.25 with an A. L. A. M. rating of 29 horsepower and a piston displacement of 297.8 cubic inches. The chassis with a 120-inch wheelbase carries a seven-passenger body with complete equipment including Delco lighting, starting and ignition system, Stewart vacuum-gravity gasoline feed, Stromberg carbureter with hot air connection to a jacket on the manifold, motor-driven tire pump, electric horn, speedometer set flush in instrument board, automatic, full-ventilating rain-vision windshield, and other features such as quickly-detachable top curtains, etc. Helical gears are used in the Timken rear axle and Firestone demountable rims are regular equipment.

Averaged Over 24 Miles per Gallon

This is the car that in a recent official test under A. A. A. sanction at the Indianapolis speedway traveled over 24 1-8 miles to a gallon of gasoline with the car carrying full equipment and seven passengers. It showed 53 miles per ton of weight on a gallon of gasoline, which is equivalent to carrying 1 ton of weight 53 miles on 1 gallon of gasoline.

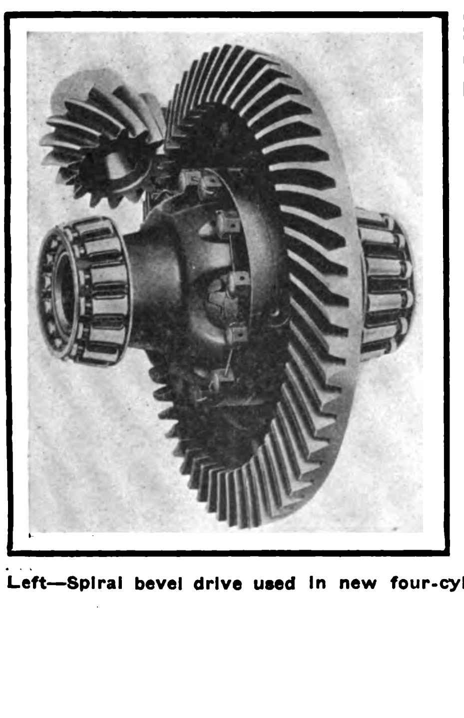
Besides this without any adjustments it showed consistent running for a half-hour non-stop test at a fixed speed of 55.63 miles per hour.

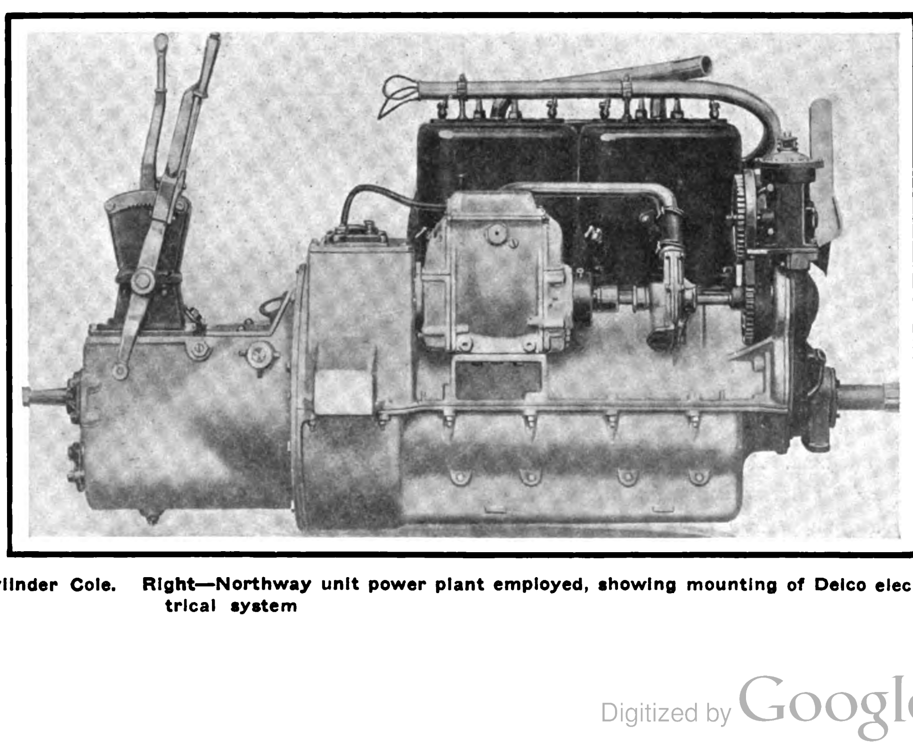
Streamline Body—Folding Auxiliary Seats

The body is a stream-line design, having neither rise nor drop in the cowl. The radiator, hood and body are blended into one another by having all the lines of the radiator diverged into the body. The front seats are of the individual type with a 7.5-inch aisle between. There are four doors, all operative, and exceptionally wide, 22 inches in front and 24 inches in tonneau. Folding auxiliary seats with disappearing irons are regular equipment.

With the aisleway between the front seats the operation of raising or lowering the one-man top is simple. Drop forged steel standards for carrying the one-man top are used. The top is manufactured throughout to be right when up.

A leather-faced cone clutch forms the connecting link between the motor and the gearset. The aluminum cone is





Left—Spiral bevel drive used in new four-cylinder Cole. Right—Northway unit power plant employed, showing mounting of Delco electrical system

14 7-8 inches in diameter and 2 1-2 inches wide, with an 11-degree face angle. The clutch hub bearing is of the annular ball type, and a ball thrust bearing is provided for the throw-out mechanism. Six coiled springs hold the clutch in engagement. A brake is provided on the clutch.

The shafts of the transmission are made of chrome-nickel steel, and are mounted on annular ball bearings. A roller bearing is used where the sliding gearshaft floats in the clutch shaft extension. The gears are all of .75-inch face; forged from chrome-nickel steel. Both the main shaft and jackshaft are 1 1-2 inches in diameter. The jackshaft is only 6 5-8 inches long between bearings.

A Spicer universal joint is used at each end of the drive shaft which is 1 3-8 inches in diameter. The rear axle is Timken with helical pinion drive. The gears and shaft are forgings of chrome-nickel steel. The driving gears are of 4 1-2 pitch, with stub teeth, and have 1 3-8-inch face. The driving pinion is supported by two roller bearings on a 1 1-2-inch shaft. The pinion shaft is of chrome-nickel steel. The drive shafts have six-jawed clutches on their outer ends which mesh with jaws in the steel hubs.

The internal and external brake drums are 15 1-2 inches in diameter by 2 1-2 inches wide and are faced with autobestine, an asbestos fabric.

The semi-elliptic front springs are 37 1-4 inches long, 2 inches wide, and the spring's eyes are bushed with phosphor bronze. The three-quarter rears, 50 1-4 inches long. Firestone demountable rims are fitted as standard equipment.

The Gemmer steering gear is mounted on the left side, and an 18-inch corrugated wheel is used. The steering gear itself is the worm-and-full-gear type.

The double drop frame, which has a section 4 1-6 inches high is extended to the rear of the body to form a support for the gasoline tank. The 7 1-4-inch kick-up in the frame over the rear axle allows a wide spring action.

Besides this model the company continues its six at $1,865 and a big six at $2,465.

To Re-Open Van Dyke Bankruptcy Case

DETROIT, MICH., Oct. 27—The bankruptcy case of the Van Dyke Motor Car Co., which was closed in December, 1912, will be re-opened, permission having been granted by Judge Tuttle, of the United States Circuit Court. The Columbus Bolt Works, Columbus, one of the creditors, petitioned the court, claiming that about 200 stockholders or other persons which had subscribed for stock in the Van Dyke company never paid in their capital stock, which, it is claimed, represents a sum of about $200,000. The court now decided to re-open the case upon seeing the list submitted by the Columbus Bolt Works and which shows that the stock was sold at from $6.66 to $9.00 a share although the par value had been set at $10 a share in the articles of association. The Columbus company claims that the stockholders should be compelled to pay the amounts above those actually paid for the stock, also the amounts subscribed but not paid in, as these sums constitute a part of the estate and as such should be distributed among the creditors.

New Cowles Patent on Motor Support

WASHINGTON, D. C., Oct. 23—Another Cowles patent of seeming importance in that it covers the flexible support of the motor to a cross-frame member has been issued and assigned to the Packard Motor Car Co. This patent, which is No. 1,112,678, was applied for by Edward P. Cowles of Sparta, Mich., September 6, 1901. It has as its object a flexible connection of the motor to the frame and has five claims. Claims 4 and 5 are particularly noticeable as they specify two rigid and one flexible supports of the motor to the frame. They read as follows.

Two Important Claims

4.—In a motor vehicle, the combination of a motor supporting frame comprising sidebars, a crossbar connected to said frame, a motor, supporting arms or brackets, extending laterally from the motor, means connecting said arms to said frames, and means connecting said motor to said crossbar, one of said means being flexible and permitting relative movement of the motor and adjacent parts of the frame and the other of said means being rigid and tending to limit the extent of said movements.

5.—In a motor vehicle, the combination of a motor supporting frame comprising sidebars, a motor having laterally extended supporting arms or brackets, means connecting said arms to said sidebars whereby the motor is supported thereon, a crossbar adjacent one end of said motor and connected at both ends to said frame, and means connecting said motor to said crossbar at the middle portion of the crossbar.

Curing Newly-Made Tires in Federal Plant

¶ The process of curing, so often referred to by the rubber experts, is clearly shown in the accompanying illustration taken at the Milwaukee plant of the Federal Rubber Mfg. Co. About a dozen newly made tires, tightly wrapped in canvas tape, and compressed under hydraulic power into steel cases, are placed in one compartment. The lid fits closely over the vat, so as to keep it airtight, and live steam is shot into the space around the tires. The steam softens the tires until they conform to the shape of the steel molds in which they are encased. After three and a half hours' immersion in the steam, the tires are taken out, cooled, and wrapped for shipment to the purchaser or dealer.

Curing tires at the plant of the Federal Rubber Mfg. Co., Milwaukee, Wis.

Branch Banks for South America

To Secure Credit Information, Aid Manufacturers and Exporters, Etc.—Patient Effort Will Develop Opportunity

ONE of the most interesting addresses made at the meeting called by the Merchants' Association at the Hotel Astor, New York City, recently for the purpose of discussing South American trade was that by William F. Kies,* head of the foreign trade department of the National City Bank. Following is a brief digest of his paper:

Credit Information Needed

"A detriment to the development of foreign trade everywhere and in South America particularly, has been the lack of reliable credit information. It may be very easy to sell goods but it is sometimes more difficult to get your pay for them. Credit is vitally necessary to the growth of trade. No business man objects to giving credit if he knows his creditor is honest and will pay him when the bill is due. Banks are more and more relied upon to furnish opinions as to the financial responsibility of business firms. It is, of course, of particular importance when your goods are to be shipped thousands of miles away to know that the man to whom you are consigning them is worthy of credit. Probably Latin-American countries are the most difficult in which to obtain credit information. The Latin-American is sensitive and with him usually credit is a point of honor. He resents inquiry for the examination of his books and rarely gives a statement. The collection of credit information, therefore, in South American countries will require the exercise of diplomacy and tact.

The compilation of complete credit files will necessarily take a long time. Capable credit men have been sent to Buenos Aires and the work of collecting credit information will be begun at once. As fast as credit files are compiled, duplicates will be sent to this country so that information concerning the standing of Argentine merchants will be available here without the necessary delay. Special credit investigations can be made whenever needed. The credit bureau is being built up for the benefit of American exporters and importers, and the information which will be collected may be had upon request.

Personal Touch Important

As the field was studied it was seen that a trained commercial representative, devoting his entire time to the promotion of American interests might do invaluable work in the upbuilding of our South American trade. Such a man would provide the personal representation so much needed. It has been arranged to have such a commercial man to make it with each branch. His duty will be to study closely local markets in an endeavor to develop trade opportunities for American merchants. He will form a close personal acquaintance with local business men and in Spanish speaking countries the value of a personal acquaintance cannot be over-estimated. He will endeavor to interest local merchants in American goods. Whenever a real trade opportunity arises he will cable to New York and the various lines interested will be notified by special letter. He will be in a position to make special investigation for firms desirous of ascertaining whether a market exists for their product. He will be able to ascertain the style and character of the goods in demand in the market, how they are packed, the price at which sold and all facts necessary to enable the manufacturer here to determine the possibility of his being able to compete in the market.

In order that the general information may be properly disseminated there will be issued from time to time a publication to be known as *The Americas* devoted to the upbuilding of trade between the two countries. Trade bulletins and letters will also be used in keeping our people informed of trade opportunities and financial and economic conditions in South America.

Present Conditions Favorable

Present conditions are favorable for the ultimate commercial success of this country in South America; but we must not enter into this big trade movement with the idea of getting immediate large results. Argentine and Brazil have been through a long period of depression. Brazil owing to the failure of the negotiations for her $100,000,000 loan with English interests is in financial straits. The value of the milreis, the monetary standard, has depreciated 20 per cent. and there will be great difficulty in the marketing of the large coffee crop while the market for her tobacco is closed.

Argentina for the present and immediate future has probably the best prospects of any South American country. A picture of her immediate financial prospects and her possible purchasing power may be drawn from the following statistical review just received by cable:

Of the total corn crop there still remain 110,230,000 bushels unsold. Present price, 52 cents per bushel.

The estimated surplus of wheat over domestic requirements is placed at 24,046,000 bushels, with the market price $1.16 per bushel.

There still remain 6,613,800 bushels of linseed for export, the market price being $1.19.

The entire old crop of wool has been disposed of and the shearing of the new crop begun. A normal crop of 310,000 weighing 880 pounds is expected which, at the average price of 19 1-3 cents per pound, would bring $52,650,400.

The price of cattle to producers has increased in the past few months from $46.80 to $76.57 per head, production for the present year being estimated at 1,500,000 head. The entire output will be marketed advantageously. The hide market is stagnant at the present time with a quantity of hides accumulating in the interior. The quantity this year for export is about $3,000,000.

The growing crops so far as reported are in good condition. The immediate prospects for Argentina are therefore good and she should recover more rapidly than any other South American nation from the effects of the European war.

Other South American countries will have difficulty in marketing their products. Chile's nitrate, like our cotton, presents a serious problem. Likewise the copper of Peru and the tin of Bolivia. But the ultimate prosperity of all these countries is not in doubt. Their natural resources are almost inexhaustible, and they will have to be a source of supply for raw materials of all kinds.

Patient Effort Required

While the situation at present is filled with difficulties and conditions at the very moment seem unpropitious, nevertheless it would seem the commercial interests of this country are confronted with a great opportunity.

*Editor's Note—The National City Bank, of which Mr. Kies is the head of the Foreign Trade Department, has set aside $1,000,000 for the establishment of a branch at Buenos Aires and also at Rio de Janeiro, the Federal Reserve Board having authorized their establishment. The staff for the Buenos Aires branch has been selected and is on its way. The branch will be in operation early next month. The staff for Rio de Janeiro is nearly organized and the branch will be in operation before the first of the year. The operations of these branches are expected to make New York the money market for South America, at least to the extent that American bills shall be paid in dollars on New York and not in pounds sterling on London.

ABILITY to wear is the criterion that many foreigners use in the selection of a motor truck. Will it wear? This is the question they endeavor to solve. Parts must wear, and have they provision for adjustment? Can you adjust the bushings of the steering gear when they wear? It is cheaper to adjust than to replace. It is much quicker and in either war or industry the economy of time is a vital factor in truck operation.

So adjustment and accessibility become real factors in truck work. So Europe considers it, and as Europe is the big buyer today, it is quite necessary that these matters be conspicuous. But adjustability and accessibility are not important solely because Europe thinks so. Our own conditions demand them. Our industries demand such; and should our nation make large purchases of trucks for war purposes or determine on some form of truck subsidy system these factors would be equally important.—Editorial in THE AUTOMOBILE, *October* 8, 1914.

WEAR

The Necessity for Balance Among Wearing Parts in Cars and Trucks

The Real Strength of Truck Is That of Weakest Part

By John W. Watson
Member Society Automobile Engineers,
President of the American Bronze Co.

BERWYN, PA.—Editor THE AUTOMOBILE:—The problem of every man or concern operating motor vehicles, whether for the delivery of goods or for the transportation of passengers, is to keep these vehicles on the road where they earn money and out of the shop where they cost money.

To have a fleet of six trucks or six taxicabs and average but five of them on the road and one of them in the shop is certainly not very encouraging to the man having invested his money in these six vehicles for business purposes.

The One Evil

Why is it that these cars must be laid up for overhauling? The answer is found in the one big word wear. If there was never any wear there would be mighty few interruptions to continuous service. The occasional breaking of some part would be all that could then interrupt service and entail expense.

Wear, though, we will always have. Between any two moving parts there is always friction and friction causes wear to a degree dependent upon the quality of the metals in contact with one another.

Where Found

The bulk of parts in the makeup of any motor vehicle are in no way subjected to wear, there being no movement between these parts and the parts to which they are bolted. Let us analyze and see what parts *are* subjected to wear in motor vehicles. As the writer analyzes a motor vehicle its wear-subjected parts may be classified under four headings. Gears, Ball and Roller Bearings, Plain Bearings (split and therefore adjustable for wear), Bushings (solid and therefore non-adjustable for wear).

Let us now analyze a little further and see how these wear-subjected parts balance up with one another. If they all lasted for the same length of time, the car would not have to be laid up for an overhauling until all of these parts were down and out. This would be a long time indeed and any such car would prove a wonderfully profitable investment.

It so happens, though, that these four classes of wear-subjected parts, in many cars at least, come *nowhere near* balancing one another in length of service given. Let us separately analyze the wear-resisting qualities and the average life of the parts under each of these headings.

First let us take up the gears. There are motor gears, pump gears, steering gears, transmission gears, bevel gears, differential gears, etc. Present day science in the alloying of steels and in the heat treatment of steels combined with present day accuracy in the cutting of gear teeth renders these gear parts practically immune from wear. And even after years of servie when the gear teeth may have shown a little wear, there is no lost motion between the driving and the driven gear so long as the power is on. When the power is on, the gear teeth are just as snugly up against one another after wear has taken place as they are when the gears were new. If gears were the only parts which necessitated the overhauling of a car there would be few cars indeed requiring overhauling.

Bearing Wear Small

Now let us take up the ball and roller bearings. These bearings, because of the very fact that they run with so little friction and therefore show so little wear, are used in motor cars wherever construction will permit. The reason ball and roller bearings run with so little friction and show so little wear is because this type of bearing gives a rolling and not a sliding action. Present day ball and roller bearings give such long and satisfactory service that the average car owner never even finds out where they are located. Breakage, due to a defective ball, a defective roller or a defective race is practically the only circumstance which will send a car to the shop for the renewal of these parts. And defects in ball and roller bearings in these days are rare indeed.

Bushings That Wear

Now we come to the heading of split, and therefore adjustable, plain bearings. These plain split bearings, in most cars of present design, are found only on the main motor crankshaft. There are the three or more main crankshaft bearings and the four or six crankpin bearings. These bearings after a year or 2 of service show wear, but by simply dropping the oil case under the motor and removing a shim or two between the two halves of the worn bearings this wear is quickly taken up and the bearings are then ready to give another year or 2 of perfect service. This work does not involve the dismantling of any of the other parts of the car and is done at very little cost in a very short time by any average mechanic. It takes many years of hard service to wear these bearings down to the point where their renewal is made necessary.

Non-Adjustable Bushings

Now we come to the last of the four headings of wear-subjected parts. This heading covers the solid non-adjustable bushings. These bushings are found here, there and everywhere, throughout the whole car. There are the wristpin bushings, camshaft bushings, magneto and pump shaft bushings, idler gear bushings, oil pump bushings, valve plunger guides, steering gear bushings, front axle steering knuckle bushings, clutch bushings, two or three bushings in the transmission, universal joint bushings, differential pinion bushings, etc.

When new, these bushings are purposely fitted snugly to their respective shafts. These bushings *must* be snug in order to hold these shafts in their correct alignment. We have a sliding and not a rolling contact in these bushings and we therefore have friction and this friction means wear. We have the same kind of friction that we have on the main crankshaft bearings, but these bushings, unlike the main crankshaft bearings, are not split and wear on them therefore can in no way be taken up. When the bushings have worn down even as little as 2 or 3 thousandths inch, less than the thickness of this page, their period of usefulness is over and their renewal is demanded.

These solid non-adjustable bushings therefore are the parts which are sadly out of balance with the other three classes of wear-subjected parts. All of the other parts are still giving perfect service and are therefore just as good as new, and yet the car must be taken out of service, put in the shop and torn to pieces for the renewal of those bushings which have worn to the point where their renewal is demanded.

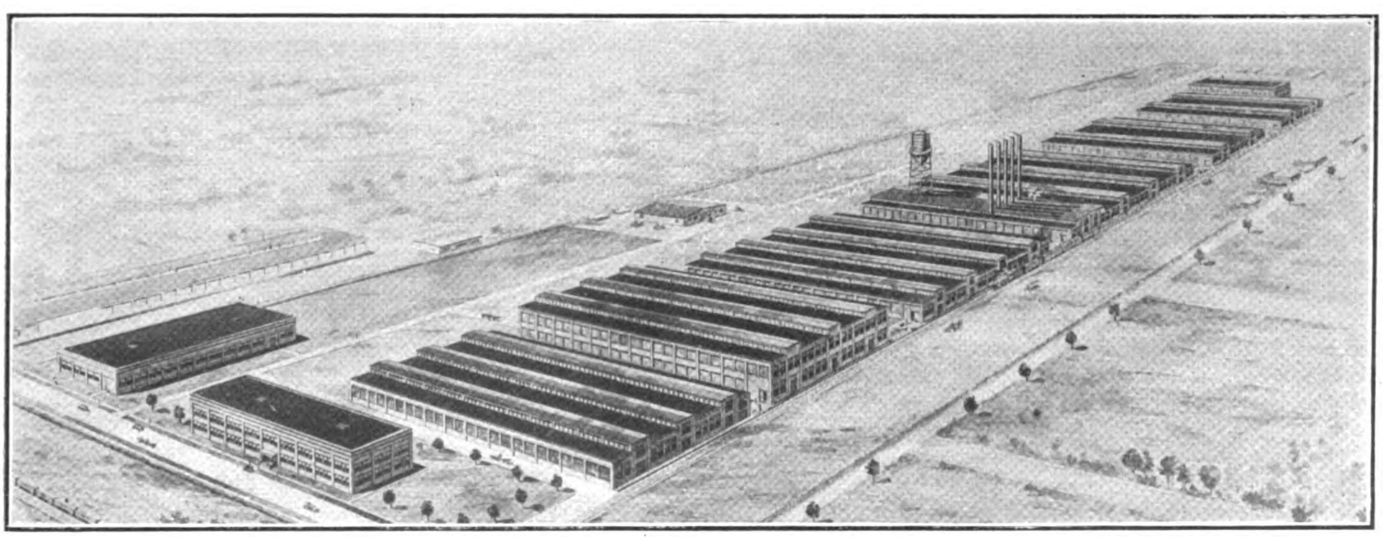
And it isn't as if all of the solid bushings wore down to this point at the same time and thus make it possible to renew them all at one tearing down. It often happens, because of lack of uniformity in bushing materials, that even bushings subjected to the same duty will not give the same length of service. In hundreds and hundreds of cases it happens that one piston pin bushing will be worn to the point of producing a bad knock before the other three piston pin bushings have shown any wear at all. And it takes just as much time and costs practically the same amount of money to renew this one bushing as it would to renew all four of them. To renew any one or more of these solid non-adjustable bushings generally means the dismantling of some entire unit—the motor, the gearset, the rear axle or some one of the several other units.

How important it is then that bushing material should be right and should be uniformly right. Inferior bushings will spell disaster to the otherwise finest of motor vehicles and superior bushings will make balanced and economical service givers out of otherwise medium grade vehicles.

The Maker's Duty

In view of the foregoing analysis as to what groups of parts are subjected to wear and then as to which of these groups will logically show first wear and require first renewal, it is clearly seen wherein lies a manufacturer's open road to vastly lessen the up-keep cost of his cars and to thus greatly increase their value. And purchasers of motor vehicles are wise who insist upon learning all that is to be learned about materials for these bushing duties and about the bushing materials which are used in the various makes of cars which are being demonstrated to them.

It is important that a car demonstrate its ability to carry the load and negotiate the hill, but it is also vastly important that the car will *continue* to carry the load and negotiate the hill. In the manufacture or purchase of a commercial vehicle it is well to always keep in mind that the value of this vehicle lies in its being on the road where it earns money and out of the shop where it costs money.—JOHN W. WATSON, President, American Bronze Co.



¶ The new plant of the Willard Storage Battery Co., Cleveland, O., when completed, will contain 6 acres of floorspace, leaving ample land for further expansion. Ten buildings will comprise the plant. All buildings will be of brick, of the latest approved and most up-to-date construction and equipped with sprinkler system throughout. The various buildings will be entirely separate, sufficiently isolated from each other to insure adequate protection from fire, and to furnish the maximum of light and air. The plant was described in THE AUTOMOBILE for October 22. Both factories, the old one at present occupied, and portions of the new plant as fast as completed, will be operated in conjunction, to afford ample production facilities for the heavy business of the early months of 1915.

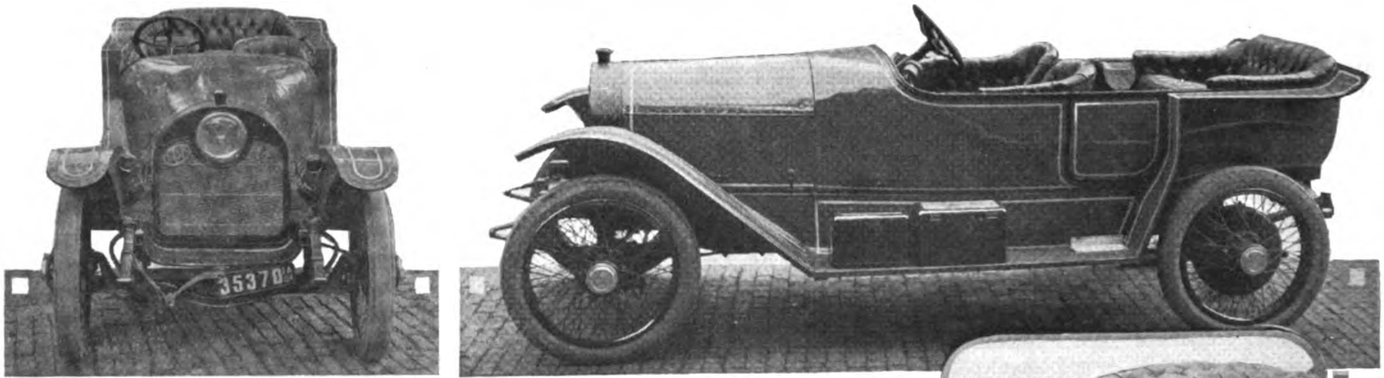


Fig. 1—Three views of car built by Iowa man. The motor has a bore of 5 1/8 inches

The Rostrum

Claims Owner's Statements of Yearly Mileage Are Generally Exaggerated

EDITOR THE AUTOMOBILE:—What is the maximum mileage per year for a private machine? That question and discussions arising from it have been of singular interest to me for the greater part of the 14 years I have been associated with automobiles.

The talk one hears in garages, factories, repair shops, etc., leads the novice to have as little respect for 10,000 or 20,000 miles, as he should have for 1,000.

Fifteen to 20,000 miles in the 3 or 4 summer months is a common boast of the majority of tourists you meet, and it is very, very seldom that I find a man that really has any idea of how far a car can actually travel in a series of consecutive days, driven constantly.

A short time ago a certain manufacturer of high-grade cars issued a guaranteed statement that five of his machines had in 5 years traveled an *average* of 200,000 miles *per car*, or 40,000 miles per year per car for 5 consecutive years! And I suppose a large number of people read and believed this statement. As a matter of fact such a performance is an absolute physical impossibility, it simply could not have been accomplished. Let us consider for a moment what the above figures would mean. In the localities given by the manufacturer in question the year around weather is about that of the suburbs of New York City, if anything a little more severe.

Now if a man used his car *every day that he could* and allowed 2 weeks, stretched out throughout the 52 weeks of each year for overhauling and painting, a most conservative time, if the car is on the jump continually, we find that the weather would permit him on, an average to run 300 days each year. This means that EVERY DAY he must run 133 1-3 miles, not letting up ONE DAY HE CAN OPERATE in 5 years. If he does not go out one rainy day he must do 266 2-3 miles the next, and so on. Just reason it out a minute or two and one will see how absurd such a statement is.

The man that says he does 15,000 or so miles in 3 months is just that much more off on his reckoning.

For the fellow who has just bought a car or who is going to buy one, or has driven for some time and wonders about the great mileage others make, it may be of interest to know that the actual mileage of an automobile, driven by a chauffeur, and given hard usage, is very seldom over 9,000 to 10,000 miles a year, whereas a privately driven car does well if it makes 6,000 to 7,000 miles in the same time. Actual average of all cars is just under 4,000 miles a year.

The above figures are arrived at after observing hundreds of cars, in many localities, and owned by people of widely different habits, for several years past.

Don't let anyone be discouraged because he cannot really make a 40,000-mile-a-year average as Smith does, because he does not.

It will really be of benefit to the automobile industry when we all learn just what 10,000 hard fought miles over our highways really means. Car mileage per year per car is an abused topic.

New Rochelle, N. Y. GEORGE C. CANNON.

Unique Car Built by Iowan

Editor THE AUTOMOBILE:—The car pictured shown in Fig. 1 was built by Hal R. Wells of Des Moines, director of the River-to-River Road and holder of the cross-Iowa speed record which he made last November in a Spaulding car. The mechanical features follow the lines of the best practice, the motor being a four-cylinder, L type, 5 1-8-inch bore. The Hele-Shaw clutch, Warner transmission of four speeds forward, and the Timken axles are used. The unique features are in the general lines of the car, the greatest width being in the center of the car and the streamlines are following out in the construction of the rear as well as the front. The width is taken care of by an 8-inch space between the two front seats, the entrance being made through two doors centrally located. Another distinguishing feature is in the arrangement of the lights. The headlight is in the center of the radiator giving the appearance of a modern Cyclops and the sidelights are a part of the inside guard for the front fenders. No lights project from any part of the car.

Des Moines. B. N. MILLS.

How Flywheels Are Fastened

Editor THE AUTOMOBILE:—1—What is the best way to fasten a flywheel permanently, which has become loose on the shaft?

2—I am using battery ignition, for a single-cylinder Cadillac, consisting of eight dry cells and a Splitdorf spark coil.

The contact points in the vibrator cause trouble. They seem to fuse and leave the contact surface so uneven that it will make the motor miss. By smoothing the points every other day there is no trouble, but this constant filing wears out the points in a short while. Is there any cause for this trouble that can be remedied?

Christine, N. D. LEWIS U. IVERSON, M.D.

—1—From your second question we take it that the loose flywheel is on a single-cylinder Cadillac. If this is so the only remedy is a new crankshaft because the flywheel on this model is attached to the crankshaft simply by pressing it in place.

This construction is unusual, as the flywheel is ordinarily fastened to the crankshaft either by keying, or bolting it to a flange on the crankshaft. In the former case the loose flywheel may be tightened by forcing the key solidly in place and then drawing up on the nut that bears against the flywheel hub. If the keyway is worn it may be necessary to make a new one slightly larger and fit a larger key.

If the flywheel is bolted to a flange, all that there is to do is to tighten the bolts. The latter method of fastening is probably best.

2—You should not use more than six cells with this coil. The trouble that you are having with the vibrator points is undoubtedly due to using eight cells, this number of cells gives too great a voltage and causes an excessive flow of current which fuses the points. There is also a danger of burning out the coil.

Bus Bodies Made by Body Makers

Editor THE AUTOMOBILE:—Can you give us the address of some one who manufactures a hotel bus which carries from eight to ten passengers? Give name of a manufacturer who makes the chassis and one who makes the body?

Salisbury, N. C. H. A. R.

—Any manufacturer of truck bodies should be able to make a suitable body for you. We know of no concern that makes a specialty of this work. You can buy a chassis to meet your requirements and then have a body built on to it according to your own ideas.

A few concerns making truck bodies are:

Borbein Auto Co., 2109 N. Ninth street, St. Louis, Mo.
Highland Body Mfg. Co., Elmwood place, Cincinnati, O.
Peters Wagon & Auto Works, Baltimore, Md.
Collins Vehicle Woodwork Co., 3900 Chouteau avenue, St. Louis, Mo.
Cooling Carriage Co., 402 French street, Wilmington, Del.

Description of Piping on Cadillac Eight

Editor THE AUTOMOBILE:—Will you please explain and show by diagram, if possible, how the piping is arranged on the eight-cylinder Cadillac? It would seem to me that there would be some difficulty in arranging the different pipes so that they do not interfere with each other.

Norwalk, Conn. E. J. V.

—A diagram of the piping is shown in a simple manner in Fig. 2. The intake piping is short and simple, the carbureter being placed directly between the cylinder blocks and short pipes from it connecting with each set of four cylinders. Two separate exhaust pipes are used so that there will be no danger of interference. The water piping is also very simple and direct. There is a separate pump for each cylinder block, as shown, and the inlet and outlet connections to and from the radiator are short pieces of hose. Gasoline piping is standard, the tank being located at the rear of the chassis and the fuel being forced to the carbureter through air pressure supplied by a small pump.

Origin of the Word Automobile

Editor THE AUTOMOBILE:—We have been unable to ascertain after considerable inquiry the original cause for the use of the word automobile, and how it originally became connected with the vehicle we know by that name today. Can you tell us?

Memphis, Tenn. THOS. H. SMART.

1—The word Automobile comes from two words; one Greek and the other Latin. The two words are auto and mobile. The former is derived from the Greek autos, meaning self and the latter from the Latin mobilis, adverb, movable. This is originally derived from the Latin verb, moveo, movero, movi, motus, meaning to move. We are unable to say who first suggested this word as the name for self-propelled vehicles.

High-Compression Motor More Powerful

Editor THE AUTOMOBILE:—1—What is the difference between a low and high compression engine?

2—How can I change a low-compression motor to a high compression one?

Canton, N. Y. A. W. E.

—1—The terms low and high used in this sense are, of course, purely relative. A motor with 40 pounds compression might, however, represent one limit and one with 100 pounds the other limit. Fifty to 60 pounds compression is the average.

The low-compression motor gives smooth running, it is easy to crank and the stresses in it are not large, but it is not so economical nor so powerful as the high compression design. The latter is more liable to overheat and to knock.

2—The compression may be raised by several methods. It is hardly advisable to make this change because your motor has been designed for a certain compression and if you raise it, say 10 pounds, you will submit the cylinders to a greater strain than they were designed for; the pressures on the cylinder walls will be greater and the wear on the bearings more. If your motor is not giving the power you should find out what is the matter with it rather than raise the compression.

Probably the best method is to rivet a plate to the top of

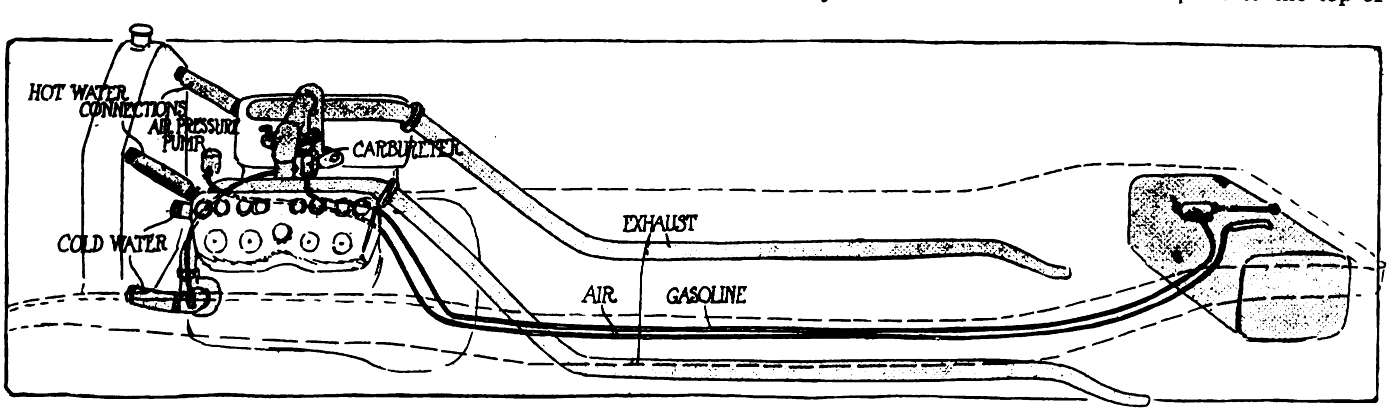

Fig. 2—Diagram showing the piping on the Cadillac eight-cylinder car

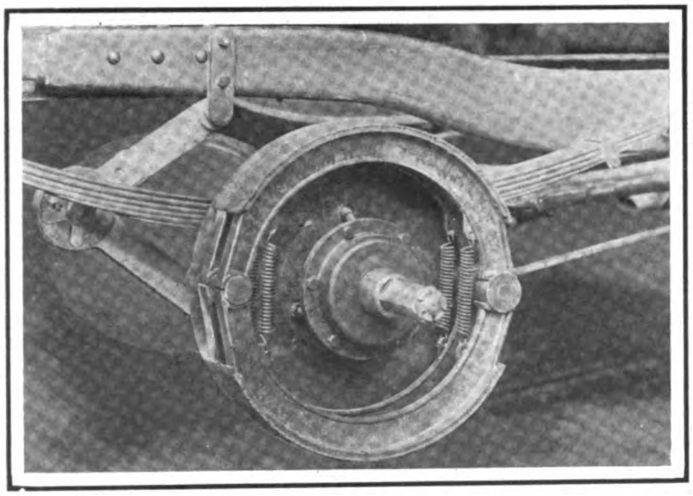

Fig. 3—Illustration showing the construction of dual expanding brakes

the piston or the cylinder, whichever is more convenient. Placing the plate on the piston adds weight to the reciprocating masses while if it is attached to the cylinder head there is danger of interference with the flow of the gases in and out. In either case, be sure that there is clearance enough between the piston and the cylinder to allow the plate to be put into place. If the plate is attached to the piston it should be made of aluminum for the sake of lightness.

Lengthening the connecting-rods or increasing the crankshaft throws will also increase the compression. But neither of these methods are as simple or as cheap as the first one suggested.

Motor Vibration Reduced by Weighing Parts

Editor THE AUTOMOBILE:—I am planning to overhaul my car this winter and as it vibrates greatly at speeds above 20 miles per hour I would like to know if there is any way of reducing it?

Elyria, O. SUBSCRIBER.

—This is largely a question of bringing the reciprocating parts to the same weight. Remove the pistons and the connecting-rods. Weigh all the pistons with the wristpins, and remove metal from the heavier ones until they are all exactly the same weight. Do the same with the connecting-rods.

Advantages of Dual Expanding Brakes

Editor THE AUTOMOBILE:—I note that some cars have both sets of brakes placed inside the rear wheel drums, and that both sets are expanding instead of having contracting bands on the outside and expanding bands on the inside. Will you please illustrate this construction and explain its advantages?

Norfolk, Va. J. A. BARNES.

—Fig. 3 shows how the double expanding brake construction is applied to the Stutz. The two sets are identical and both are operated by cams. The main advantage of this construction is that both sets of brakes are protected from dust, dirt, mud and oil.

Missing Caused by Cold or Dirt

Editor THE AUTOMOBILE:—Can you please tell me what the trouble is with an R. C. H. car which acts as follows: It will run perfectly for a mile or longer, then go badly. Going up grades, or fast on the level, it acts worst. It will either backfire, skip or choke up, with the carbureter adjusted the best that any of the automobile experts here can do. It has a new Model B Stromberg carbureter, new Never-leak rings and new plugs, also new points on the timer. The motor will run until it gets so bad that it will die with the clutch out. Then if I get out and crank the machine, it will go perfectly until speeded up or long grade is made. It acted about the same with the old carbureter. When it is working right it has good power.

Lowville, N. Y. CHAS. A. RUMBLE.

—There are two possibilities. If you have no hot air attachment on this carbureter, the poor running may be due to condensation of the fuel in the intake pipe. If this is so you should buy a hot air connection. It is a simple matter to install it.

It may also be that there is dirt in the fuel line. When this dirt gets under the float valve it causes flooding of the carbureter and missing, and may stop the motor, and at other times some of the dirt may obstruct the passage of the fuel in the pipe or up through the spray nozzle, giving a weak mixture and producing back fires.

Steel Disk Clutch Coefficient .07

Editor THE AUTOMOBILE:—1—What is the coefficient of friction between the polished steel disks of a well-lubricated multiple-disk clutch? I have accepted same to be 0.036.

2—Does the experience gained from automobile clutches verify this figure?

Waynesboro, Pa. G. A. ANDERSON, M. E.

—1—The coefficient of friction depends on the conditions of the surfaces, the viscosity of the lubricant and the pressure between the disks and therefore it is difficult to give a figure for the coefficient or friction. Probably .07 is a good average value, however.

2—The coefficient of .036 might be found to obtain in certain cases.

Spaulding Car Has Bed

Editor THE AUTOMOBILE:—Will you please advise me if you know of any automobile that is made with the backs of the front seats adjustable so they can be laid back flat. The idea would be to have the seats laid back and make a place to sleep. A man told me he had a car of this kind, but whether it was made to order or purchased from stock, I do not know.

Garyville, La. C. M. WEEKS.

—A National runabout fitted with such a body built to order was described and illustrated in the August 6, 1914 issue page 275. The Spaulding touring car, made by the Spaulding Mfg. Co., Grinnell, Ia., also is made with a body similar to the one you suggest. This was described in the July 16, 1914 issue, page 125.

Leather Strips Prevent Body Squeaks

Editor THE AUTOMOBILE:—Would it be a good plan to put between the bolted on parts of an automobile some material that would help to eliminate the everlasting squeak that is almost always present? Do you know of anything that would be good to use for this purpose?

Augusta, Maine. GEO. E. GAY.

—If you are referring to body squeaks these may be eliminated by placing leather or lead strips between the parts that are causing the noise. There is no objection to the use of these strips except that it is a certain amount of trouble to apply them.

Wants Starter for Buick

Editor THE AUTOMOBILE:—I have a 1913 Model-25 Buick, and would like to have you recommend a starter which could be installed on this car at a reasonable price, and which would give satisfaction.

Nashville, Tenn. K. C. HARDCASTLE.

—Below is a list of starters taken from the *Automobile Trade Directory*, one of which you might use. All types are included because you have not given very definite information as to the kind you want.

Compressed Air

Auto Air Appliance Co., Annapolis, Md.
Crescent Co., Detroit, Mich.
Gemmer-Detroit Starter Co., Dime Bank Bldg., Detroit, Mich.
Ham-Meix Mfg. Co., West Eleventh street, Indianapolis, Ind.
Janney Steinmetz & Co., Philadelphia, Pa.
Kellogg Mfg. Co., 3 Circle street, Rochester, N. Y.
Lipman Mfg. Co., 211 Pleasant street, Beloit, Wis.
Manzel Bros. Co., 320 Babcock street, Buffalo, N. Y.
Thurber Rotary Starter Co., Detroit, Mich.

Electric

Adams Bagnall Electric Co., Cleveland, O.
Apple Electric Co., Newark, N. J.
Dayton Engineering Laboratories Co., Dayton, O.
Dyneto Electric Co., Syracuse, N. Y.
Electric Auto Lite Co., Toledo, O.
Emerson Electric Mfg. Co., 2024 Washington avenue, St. Louis, Mo.
Fisher Electrical Works, Detroit, Mich.
Gray & Davis, Boston, Mass.
Hartford Suspension Co., Jersey City, N. J.
North East Electric Co., Rochester, N. Y.
Remy Electric Co., Anderson, Ind.
Rushmore Dynamo Works, Plainfield, N. J.
R. C. Wells Mfg. Co., Station A, Fond du Lac, Wis.
Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.

Hand

Automatic Appliance Co., 162 Columbus avenue, Boston, Mass.
Bremer Wilson Mfg. Co., 1421 Michigan avenue, Chicago, Ill.
Knapp Bros. Starter & Equipment Co., 24th and Central avenues, Minneapolis, Minn.
National Motor Device Co., 3901 Ellis avenue, Chicago, Ill.
Perfection Auto Starter Co., 1551 Broadway, Denver, Colo.
Sanbo Starter Co., Bennett, Iowa.

Spring

American Ever Ready Co., 316 Hudson street, New York City.
Automatic Devices Co., Galesburg, Ill.
Elder Mfg. Co., 2305 N. Illinois street, Indianapolis, Ind.
Gardner Engine Starter Co., 1451 Michigan avenue, Chicago, Ill.
Modern Auto Starter Co., 2127 Indiana avenue, Chicago, Ill.
J. W. Tudor, 35 Congress street, Boston, Mass.

Quantity of Acetylene to Drive Ford

Editor THE AUTOMOBILE:—1—Regarding using acetylene gas from Prest-O-Lite tanks or carbide generator to run a Ford in an emergency, for cold weather starting would it take more or less than the two headlights use?

2—Would it damage the engine to turn it on full force?

3—How far would a cubic foot of gas run a Ford?

Danforth, Me. H. H. LANE.

—1—Much more gas would actually be required for running the motor but in the course of a week or month probably the total consumption of acetylene by the lights would be greater.

2—It would hardly damage the motor but it might give too rich a mixture for combustion.

3—Approximately 600 feet with throttle wide open. This is figured as follows: A cubic foot of gas requires 2.5 feet of pure oxygen according to the chemical equation, acetylene, 2 C_2H_2 + oxygen, 5 O_2 = water, 2 H_2O + carbon dioxide, 4 CO_2. In other words five volumes of oxygen are required for every two of acetylene and since oxygen comprises approximately one-fifth of the air, twenty-five volumes of air are required for every two of acetylene, that is, for every cubic foot of acetylene 12.5 cubic feet of air are required. In other words 12.5 plus 1 cubic foot of gas must be taken into the cylinders. If the cylinders of the Ford took in full charges each time, the motor would consume 176.7 cubic inches or .102 cubic feet every two revolutions or 13.5 cubic feet of mixture would rotate the motor 265 revolutions. With a gear ratio of 3.64 to 1 this would correspond to 72.8 revolutions of the rear wheels. Since the wheels are 30 inches in diameter, in one revolution they will traverse a distance of 94.5 inches or approximately 8 feet and this multiplied by 72.8 gives 584 or nearly 600 feet. This figure is based on the assumption that the throttle is wide open: with the throttle only partly open the car would be driven much farther.

How to Adjust Matheson Steering

Editor THE AUTOMOBILE:—Will you please explain the adjustments on the steering gear used on the Matheson Silent Six?

Toronto, Ont. A. B. KEYS.

—Fig. 4 illustrates this steering gear. The principal adjustment is that which compensates for wear in the worm and sector. This is provided for by means of an eccentric bushing which is securely locked by a small headpin which engages notches milled in the head of the bushing. By removing the clamping bolts of these pins and removing the pins the thickness of the heads so as to clear the head of the bushing, the bushing may be turned around so as to move the sector either into or away from the worm, giving the adjustment for wear. The adjustment of the column vertically can be made by loosening the clamping bolt A on the collar B and by screwing this collar up or down the ball bearings may be adjusted.

The motion of the wheels is limited by two set screws C, which are adjustable stops for the steering gear and thus limit the motion of the front wheels.

Average Tire Mileage, 5,199 Miles

Editor THE AUTOMOBILE:—Have you any information at hand regarding the life of pneumatic tires, both shoes and tubes?

Mt. Vernon, N. Y. E. H. C.

—According to an extensive test made by W. A. Weygandt, Akron, O., an account of which is given in the October issue of the Automobile Trade Directory, the average mileage per set is 5,199. The average number of casings replaced for any and all causes is three-fourths of one for each set of tires used. The average life of an inner tube is found to be 8,543 miles. Ten different makes of tires were investigated, the number of sets of each make varying from forty-three to three, the total number of sets being 145. The highest mileage by any one make was 6,221 while the lowest was 2,816.

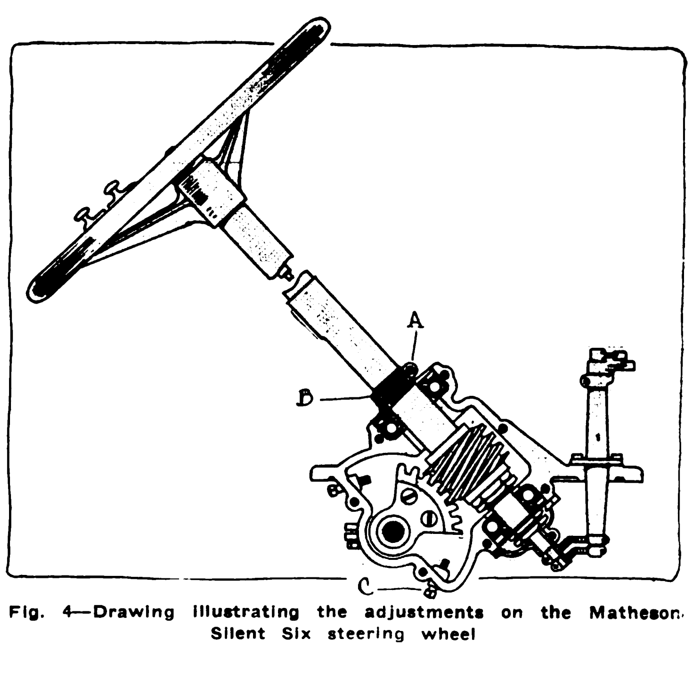

Fig. 4—Drawing illustrating the adjustments on the Matheson Silent Six steering wheel

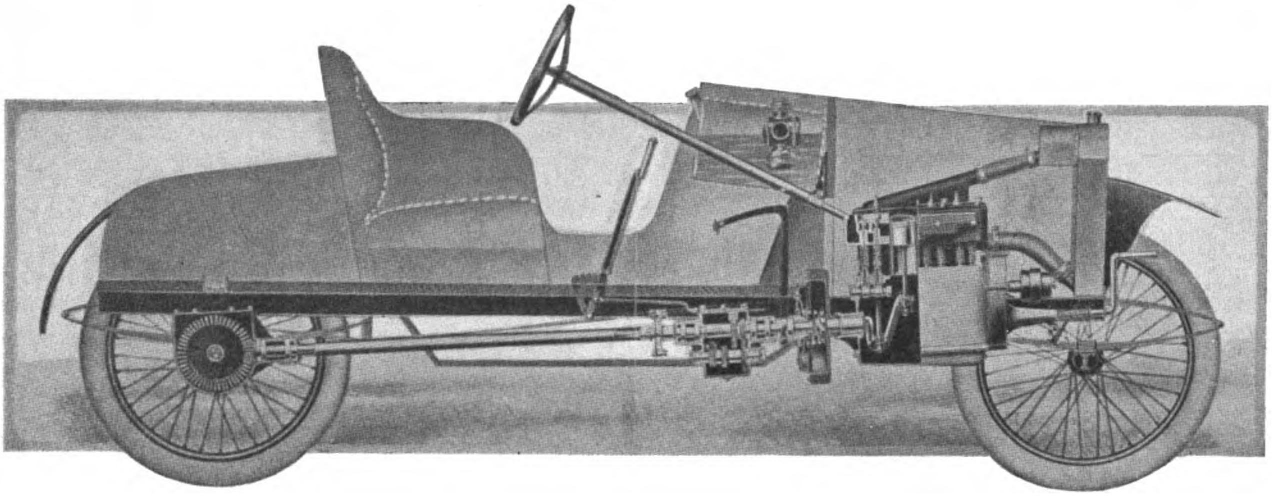
Four-Cylinder Argo $295—Has Shaft Drive



Four-cylinder Argo, showing power plant, two-speed sliding gearset, shaft drive and fuel tank in dash

IN bringing out the Argo car, Benjamin Briscoe and his associates in the Argo Motor Co., Inc., Jackson, Mich., have undoubtedly reached a very low price level, the machine being offered at $295. It is equipped with a four-cylinder, water-cooled motor, has shaft drive and a sliding gearset. The total weight is given at 750 pounds, the wheelbase is 90 inches and tread 44 inches. Cars are now being produced at the plant in the Michigan city, and it is expected to soon get under way at a good rate.

Motor Characteristics

The motor 2 15-16 by 4, is of the L-head type having cylinders and crankcase cast in one block. Access to the crankshaft bearings is through the plate at the bottom of the case. Three-point suspension is used.

The car drives from the left, and spark and throttle levers are on the steering column. With gearshift in the center, and with a single pedal to operate the clutch and braking system, the operation of the car is made very simple. The brake drums are 8 inches in diameter.

Wire wheels are fitted, and they carry 28-inch tires. Only one body type is fitted, that being the open-sided roadster which gives comfortable accommodation for two passengers, the seat measuring 24 by 42 inches, and there being 38 inches of leg room.

Gasoline consumption is low, figuring to from 35 to 40 miles per gallon, it is said. Speeds anywhere from 5 to 40 miles an hour are attainable on level ground, while the car can negotiate a 10 per cent. grade on high gear.

Top and windshield are supplied at an additional cost of $20.

The motor, which has a horsepower of from 8 to 12, is a good example of the development which has come in the last year or so in the making of the small four-cylinder type. The moving parts, valves, camshaft, crankshaft, pistons and connecting-rods are all designed along the same lines as larger motors.

In order to combat vibration, to insure against excessive wear and to allow of high piston speeds, the reciprocating parts have been made light in weight, the total for piston, rings, wristpin, connecting-rod, bolts and bearings being less than 2 pounds, it is claimed.

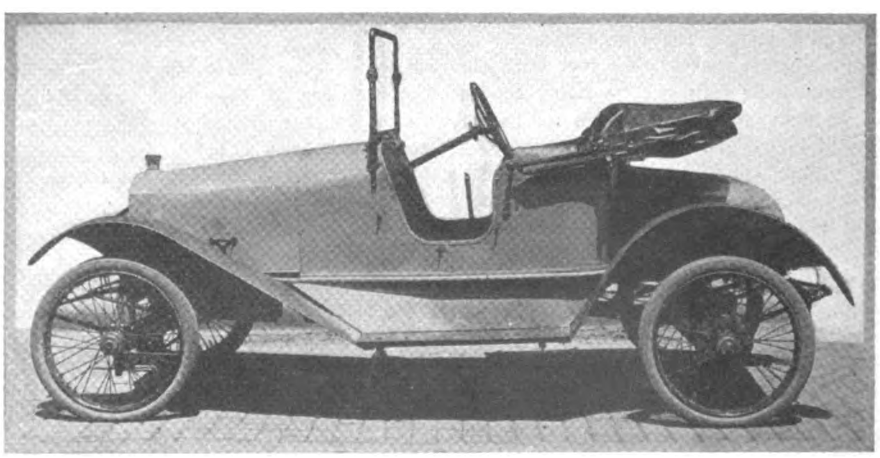
The valves on the right have a diameter of 1 3-16 inches. They are interchangeable, have adjustable push rods, and tappets bearing on the cams. The crankshaft, of carbon steel, works in two main bearings. The front one measures 1 3-16 inches diameter by 1 5-8 inches length, and the rear is 1 3-8 by 2 inches. Drop forged connecting-rods are 9 inches long and have two-bolt strap ends and connect to the pistons by 1-2-inch steel pins. Camshaft diameter is 1 inch.

The motor uses Atwater-Kent ignition apparatus, gets its gasoline by gravity feed from a 6-gallon tank under the cowl, is cooled by thermo-syphon in connection with a honeycomb radiator, and is lubricated by a self-contained, constant-level system in which the rod ends splash oil to the bearing surfaces and the level is maintained by a cam-operated plunger pump. The oil reservoir capacity is 6 quarts.

The motor is not of the unit power plant type, the gearset being placed amidships and hung from the frame. Consequently, the flywheel is not housed in, and in it is placed the internal cone type of clutch which is leather faced.

The sliding gearset provides two forward speeds, and reverse. The control lever is in the center.

Back of the gearbox, the propeller shaft is fitted with a universal joint, after which it enters a torsion tube attaching at its rear end to the rear axle housing. This tube takes the drive. The rear axle is semi-floating and has bevel drive with a ratio of 4 to 1, the gears being of chrome vanadium steel and shafts carried on ball bearings. Elliptic springs are used front and rear.



Side view of Argo, showing wire wheels, left drive and center control

The Engineering Digest

Slidable Camshafts—In This Case Arranged for Compression Relief Only

AMONG the more obvious means for securing reserve speed and power for a motor intended to be operated normally at a maximum of, say, 1,000 revolutions per minute, an arrangement for having the camshaft slidable and the cams formed so as to produce different valve-timing at different motor speeds is frequently contemplated, although some unsolved problems with regard to the shaping of the cams and tappet rollers are involved, as well as new dispositions for bringing the gear speeds into harmony with the desired vehicle speeds in each case and with the enlarged range of useful motor speeds. As against these difficulties, the advantages to be gained by a practicable consummation of the plan seem sufficiently important—in the way of reduced motor dimensions, improved fuel economy and efficiency at all speeds and reduced wear or deterioration of the motor speed selected as normal—to make designers pay considerable attention to the problem, and sooner or later motors may therefore be looked for to appear which may be operated with full volumetric efficiency and suitable valve-timing at any speed between 600 and 2,500 revolutions, for example. The fact that slidable camshafts are also employed, as by Saurer and the Panhard firm, in order to utilize the motor for braking purposes on long declivities, and for facilitating motor-starting by relieving the compression, renders the question of the most suitable mechanical means for sliding the camshaft only so much more actual, and on these grounds there is presented herewith the construction used for this purpose in Drayson motors, which are among the very few made especially for commercial vehicles in England.

These motors are made in a variety of models having 1, 2, 4 or 6 cylinders, and the illustration of the camshaft mechanism, in Fig. 1, refers to the 25-horsepower, 4-cylinder model with 4 1-8 by 4 1-2 inch bore and stroke. The object of the construction is solely to afford means for compression relief by lifting the exhaust valve slightly during the compression stroke. The *Automobile Engineer* of October 8 describes this mechanism as follows: "A large inverted tooth chain sprocket is mounted in a bearing housed in the crankcase, the camshaft carrying a long key which is made a sliding fit inside the sprocket and the sleeve attached thereto. On the other end of the shaft the bearing is capped, and a spring tends to keep the shaft pressed permanently forward, where the normal cam profile is in operation. The limit of movement imparted to the shaft by the spring is set by a collar on the shaft abutting against a ball thrust-bearing which is just discernible in the drawing, being shown in solid black at the back of the sprocket bearing. A very simple lever with a hand control is mounted outside the crankcase, the short end of the lever bearing directly upon the camshaft, so that by pulling the hand stirrup the compression release is brought into operation."

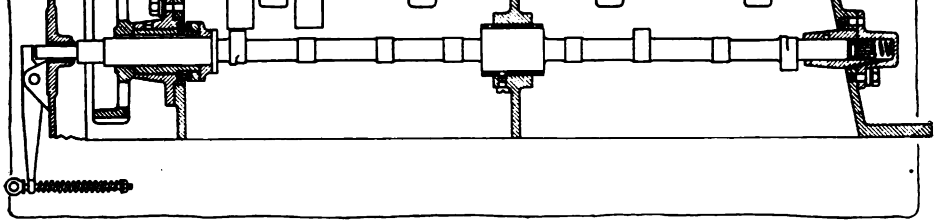


Fig. 1—Construction for sliding the camshaft in Drayson commercial vehicle motors

Decarburization of Steel Heated in Alkaline Salt Baths

IN a paper to the Iron and Steel Institute the well-known metallurgist A. M. Portevin of Paris describes the experiments by which he has ascertained that high-carbon steels suffer a considerable loss of carbon in their surface layers if they are heated in baths of molten alkaline salts, as is now common practice for the hardening operation in the case of gears and other delicate parts which should be heated very evenly in order to avoid distortion in the subsequent quenching bath of oil or water. The great rapidity with which the heating may be effected by this practice has also extended its adoption on purely economical grounds. The baths to which Portevin refers are in some instances composed of chloride of potash only, in others of chloride of potash and chloride of sodium with small admixtures of soda and ferrocyanide of potash, and in still another series of tests simple cyanide of potash is used instead of the ferrocyanide and 3 per cent. of cyanate of potash is added. In no case is the use of salts of barium mentioned.

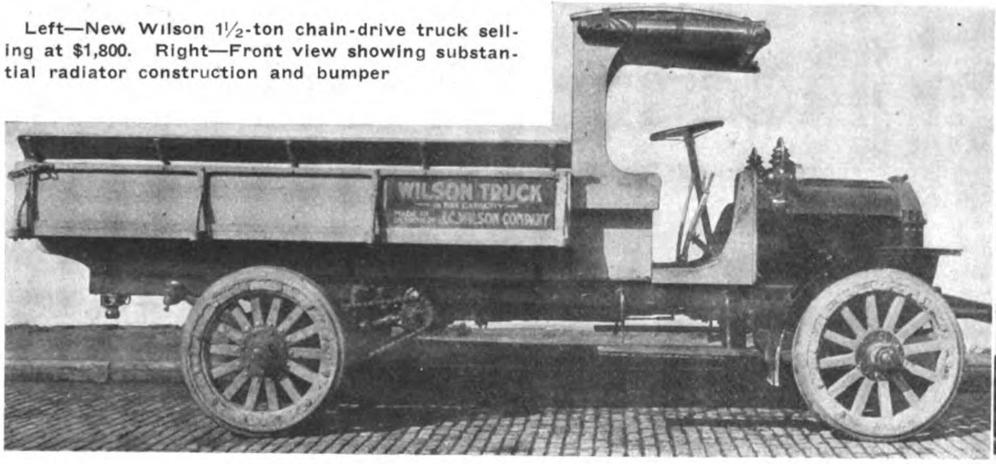
It was shown, for example, that a steel containing 1.46 per cent. of carbon came down to a carbon content of 0.9 at the surface by a 15 minute immersion in the bath, to 0.4 in two hours and to 0.2 in 5 hours; similarly that a 0.78 per cent. carbon steel came to a carbon content of only 0.5 per cent. in 15 minutes and that the decarburized layer after that length of time in the bath was from 0.1 to 0.2 of 1 millimeter thick.

On the other hand, if carbon-free Lancashire iron was immersed in the bath together with the steel, the iron absorbed carbon from the bath to a considerable extent. This was not the case, however, when cyanate of potash was added.

The depth of carburization and decarburization as well as the comparative carbon contents of the different layers were in all instances determined under the microscope from hardened, polished and etched samples.

Hardening in Cyanide of Potash

A RECIPE, probably borrowed from American practice, is given in *Werkstattstechnik* of August 15 as follows: To produce in a convenient manner a tough and hard surface on small cast-iron machine parts [perhaps the author refers to malleable iron parts—Ed.] which are subject to wear, such as small pinions and cams, they are heated to dark red and quenched in a saturated water solution of cyanide of potash which is maintained at a temperature as near boiling as possible. This is done most handily by placing the solution in an iron jar at the fire in which the pieces are heated.



Left—New Wilson 1½-ton chain-drive truck selling at $1,800. Right—Front view showing substantial radiator construction and bumper

Accessibility and Simplicity Features of New Wilson Truck

Four-Cylinder Block Motor Used in 1 1-2 Ton Truck for $1,800—Combined Gearset and Jackshaft

THE J. C. Wilson Co., Detroit, Mich., long identified with the automobile industry in body-painting and trimming branches, has entered the motor truck field with a 1 1-2-ton truck listed at $1,800. This is an assembled truck including Continental block type motor, Covert combined gearset and jackshaft together with other standard parts. The truck is made with a wheelbase of 130 inches, has left drive, with center control, the motor is carried under a conventional hood with a radiator in front, and the driver occupying the same relative position as in a touring car, a cab with side and front curtains being furnished as part of the regular equipment. Final drive is by chain. The body is so located that the rear axle is almost under the middle of the load-carrying platform.

Accessibility and Simplicity

In designing this truck accessibility and simplicity had been the two factors kept in mind, and although the truck is an assembled product, it incorporates a number of special designs in the mounting of the different parts, such as motor and gearset. The most interesting of these is that of the gearset, which is a three-speed selective type, having the gearbox bolting to the differential housing on the jackshaft. It may really be regarded as a three-point suspension in that none of the strains due to frame weaving or inequality are transferred to these parts. Instead of rigidly mounting the outer ends of the jackshaft to the frame, ball-and-socket joints are used, which relieve the constructional strains. These two mountings, together with the unique suspension of the front end of the gearbox to a combination torque member and support make up the three-point arrangement.

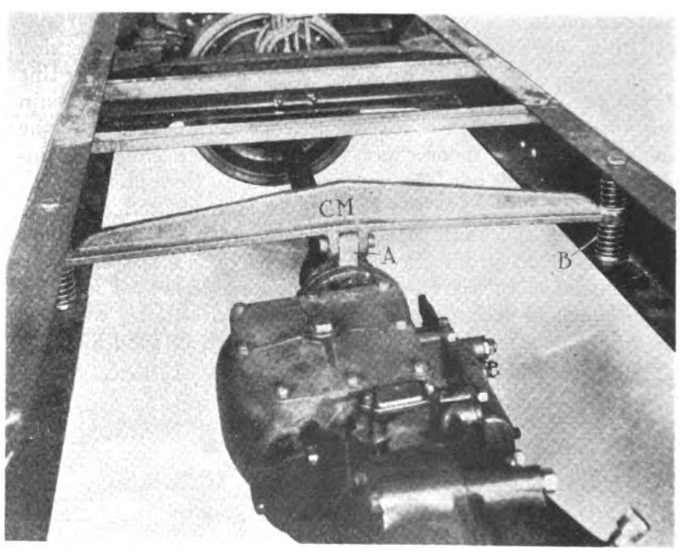
Eliminating Shocks to Jackshaft and Gears

The front gearset support is illustrated. A cross member suspends the transmission unit at its center by means of a pin connection, while the ends of this cross-piece are carried in spring buffers in the frame. Thus vibrations, driving shocks tending to twisting and road jars are not transmitted to the jackshaft or gears. By removing the pin making the connection between the gearbox and the cross-piece, the entire unit may be swung downward after the drive shaft is disconnected. This makes adjustment or inspection a simple matter.

Another place where frame weaving would cause binding has been cared for. This is the cross-shaft which serves to throw out the clutch. The ends of this shaft are carried in sockets which allow longitudinal turning of the shaft, while the sockets themselves are vertically hinged to the frame. Motion in either direction is possible, therefore, and binding cannot take place.

Both Brakes on Rear Wheels

Another commendatory feature is the elimination of brakes on the jackshaft, both emergency and service sets being placed to act on the rear wheels. This takes any brak-



Wilson 1½-ton truck, showing unique mounting of front end of gearset. The cross member C M holds it up in position through connection A. This member is supported at either end in the frame through the spring buffers B. Thus, the vibration and road shocks are not transmitted to the gearset and jackshaft. By removing the pin at B and disconnecting the propeller shaft, the entire gearbox and jackshaft may be swung downward for inspection or adjustment ing strain off the jackshaft or chains when stopping. Large size drums 14 by 2 1-2 inches are used.

Three-Point Suspension

The motor, a Continental block-cast type, 4 1-8 by 5 1-4 is suspended at three points in a rather unusual way. Integral crankcase arms are not employed, there being separate cross pieces front and rear. These rest upon brackets attached to the frame side members, and at each point of attachment there is a single bolt going through cross member and bracket. Therefore, in order to lift the motor from the frame after the drive is disconnected it is only necessary to take out the four cross arm holding bolts. With this method of attachment to the frame, three-point support is attained by hanging the front center of the motor to the center of the front cross piece, while it is suspended from the rear member by a bolt at either side of the crankcase.

Three-Bearing Crankshaft

The motor has three-bearing crankshaft and camshaft, drives the latter by gears at the front as well as the magneto and pump shaft on the right. Valves are on the left and their stems and springs are completely inclosed by plates.

Cooling includes a substantially-mounted centrifugal pump, the bearing for which is cast as a part of the crankcase rather than having the pump assembly bolting to the crankcase. This makes the pump more rigid and is a preventive of leakage due to absence of vibration. The radiator, has the tanks bolted to the shell, while the core is of tubular type. The whole is mounted on springs which relieve it of vibration.

Constant-Level Splash Lubrication

Motor lubrication is by a constant-level splash system whereby the splash troughs are kept at a given level by an oil pump getting its supply from a reservoir. Ignition by high-tension magneto is also used.

The Wilson truck employs a cone clutch, back of which the drive is conveyed to the jackshaft through a tubular propeller shaft having an external diameter of 1 3-4 inches. This tubular construction is not new to automobile construction and is just coming into vogue for truck work. Aside from its lightness, such a shaft tends to reduce whipping to the minimum. Two spicer joints are fitted, one just back of the clutch and the other ahead of the gearset. The gears have a face width of 1 inch.

Solid Tires Used

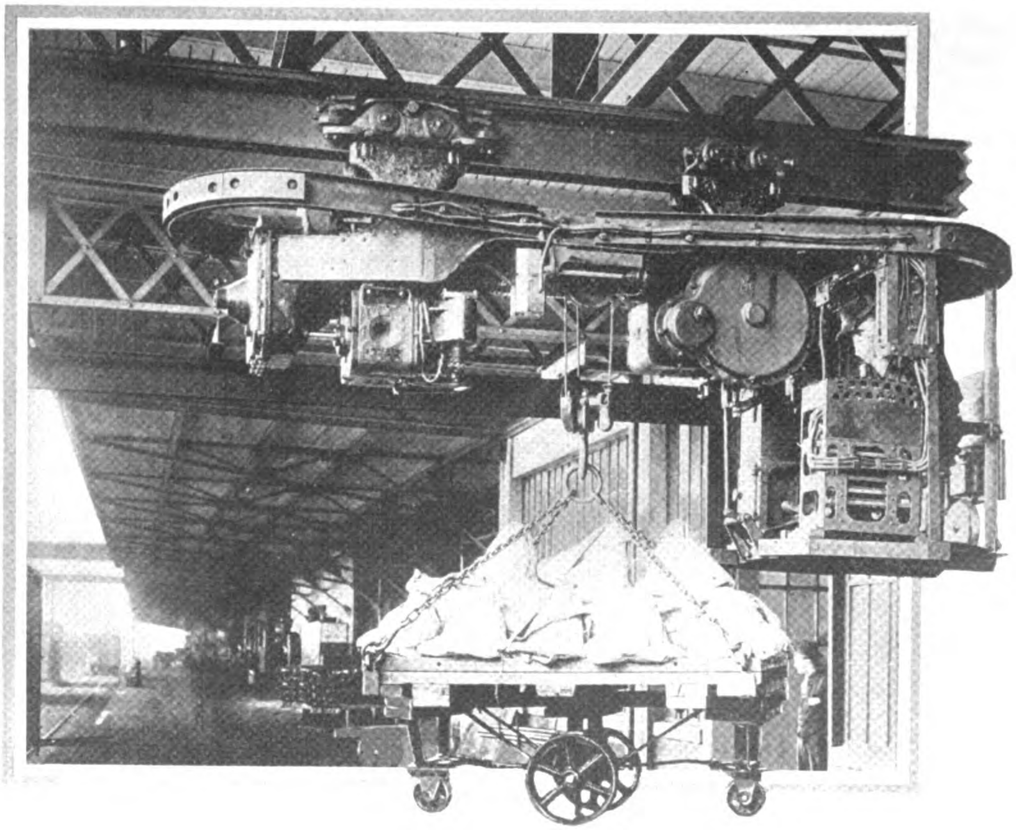
The running gear is exceedingly substantial and incorporates an I-beam front axle which has wheel spindles measuring 2 inches in diameter at the inner bearing and tapering to 1 7-8 inch at the outer; a dead rear axle having a section 2 3-4 by 1 3-4 inches with spindle dimensions at bearings 1-8 inch larger in diameter than in the front axle; artillery type wood wheels with twelve 2-inch square spokes in front, and fourteen 2 1-4 inch square in the rear. The tires are solids, the 37 by 3 1-2-inch size being used in front and 37 by 5 in the rear.

Self-Lubricating Springs Used

The frame is strongly made and braced, gusset plates assisting the cross members. The channel is 5 1-2 inches deep with a 2 1-2-inch flange, the stock being 3-16 inch. Spring suspension is by full shackled half elliptics which are made by the Detroit Steel Products Co. These have indentations in the leaves which are filled with lubricant on assembly, making them practically self lubricating. This feature together with the large number of thin leaves should make for utmost resiliency, a desirable point. The springs measure 42 by 2 1-4 front and 50 by 2 1-2 rear.

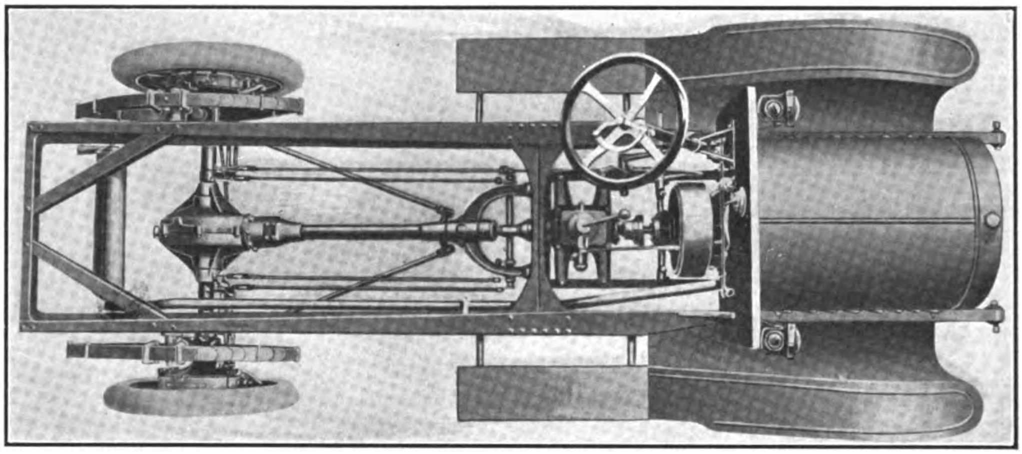
Monorail Conveyors Save Time and Labor Moving Heavy Loads in Dodge Plant

¶ The illustration at the right shows one of the Monorail conveyors employed in the factory of Dodge Brothers, Detroit, Mich. These Monorail cars run on overhead tracks, quickly and easily moving heavily loaded trucks from distant sections of the factory to the loading platform where their burdens are packed for shipment. Each of these cars does the work of from ten to twenty men. The method of operation is readily seen from the illustration, while the figure of the workman in the right hand lower corner gives an idea of the dimensions of the conveyor and its load.



G. M. C. 1,500-Pound Chassis for $1,090

Is Gasoline Type—Driver's Seat and Full Road Equipment, But No Body—With Express Body $1,215



Plan view of new G. M. C. 1,500-pound gasoline truck chassis which sells without body for $1,090

THE General Motors Truck Co., Pontiac, Mich., is now offering a 1,500-pound gasoline truck chassis for $1,090. This is without body of any kind but includes driver's seat, and full road equipment. It is also offered with flare board express body 45 by 98 inches inside for $1,215. In addition to the capacity rating of 1,500 pounds which refers to the load only, a body allowance of 750 pounds is permissible on the chassis. The complete chassis weight without body is given at 2,360 pounds.

The truck is an example of good truck engineering for the class of service which such a vehicle would naturally be called upon to perform, and its parts are amply heavy for such work. From the power plant, the power goes back through an inclosed propeller shaft to the rear axle, there being no jackshaft construction.

Four-Cylinder Block Motor

The engine is a four-cylinder, block-cast, L-head design having cylinder dimensions of 3.5 by 5 which has an S. A. E. horsepower rating of 19.6. It is capable of propelling the truck under load at speeds up to 20 miles per hour and is specially built for its heavy duty work. The power plant is three-point suspended and is located under a hood in front of the seat.

The motor is conventionally designed throughout and its working parts are constructed of excellent materials. The three-bearing crankshaft is a drop-forged nickel steel part and its bearings are of bronze-backed babbitt as are also the connecting-rod bearings. Camshaft and connecting-rods are also drop forgings, while pistons are gray iron castings fitted with three rings and having a length of 3 3-4 inches. The piston pins are hardened and ground and work in bronze connecting-rod bushings, they being fixed to the pistons. Helical timing gears drive the camshaft and magneto and pump in the regular way. The valves are of 1 11-16 inch diameter and all of the valve mechanism is completely inclosed.

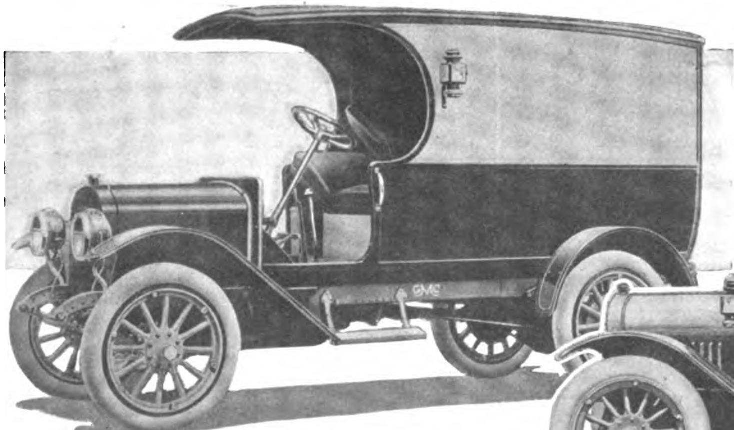
The oiling system incorporates a combination force feed and constant level splash arrangement whereby a plunger pump driven by an eccentric on the camshaft supplies oil to the timing gears. The oil drains back to the constant level splash pans under the connecting-rods for lubricating by splash the pistons, connecting-rods, crankshaft and camshaft bearings.

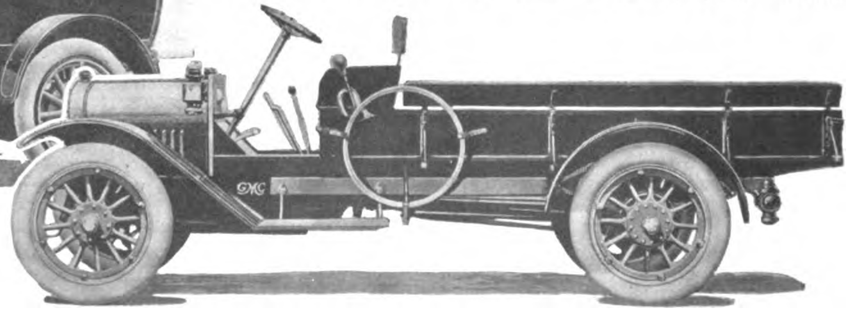
A substantial tubular radiator specially designed for truck service is the main cooling agent, being aided by the centrifugal pump and the ball bearing, belt-driven fan. The ignition system is of the single type with jump spark.

Back of the motor, the power is transferred to the rear through a cone clutch acting in the uninclosed flywheel. The clutch is leather-faced and has spring inserts to effect gradual engagement. Between the clutch and the gearset which is located amidships on the end of the motor subframe, there is a universal joint which is an advantage for transmission efficiency.

Three-Speed Gearbox

The gearset, with its levers directly over it for center, control is of the three speed selective type. The gears are of heat-treated nickel steel while the shafts are of a high carbon steel carried on ball bearings. Back of the gearbox, the propeller shaft enters a torsion





Above—New G. M. C. delivery type on 1,500-pound gasoline truck chassis
Right—Flare board express body type

tube fitted with a yoked front end hinging to the frame cross member. There is another universal between the torque tube and the gearbox. Radius rods run from the outer ends of the rear axle housing to the front end of the torsioin tube, giving a strong construction.

The rear axle to which the tube bolts through flange construction is of the three-quarter floating type with fixed drive shafts of heat-treated nickel steel. Brakes are in the rear wheel drums, external contracting and internal expanding.

The steering is on the left, operating by means of a screw and nut mechanism of irreversible type. The wheel gives ample leverage with its diameter of 17 inches.

The frame is substantially built of open-hearth pressed steel with strong bracing. The center cross-member widens at the side rails to give a good riveting surface, while at the rear the cross-member is braced by pieces running diagonally across the corners.

Springing, ever important in a truck, is very resilient in this new GMC and should tend to lessen depreciation due to vibration and jarring. The rear springs are elliptic mounted on swivel hangers outside the side members of the frame. They measure 40 by 2 inches and each half has eight leaves. The front half elliptics are 36 1-2 by 2 inches.

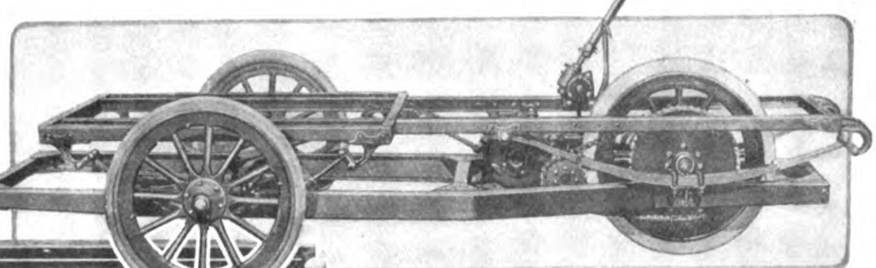
Pneumatic Tires All Around

As another factor for reducing vibration and also because of the fact that the truck is of the moderately high-speed type, the tires are of pneumatic type, front and rear, size 35 by 5. They are mounted on demountable rims which are almost a necessity when the time element in delivery work is considered.

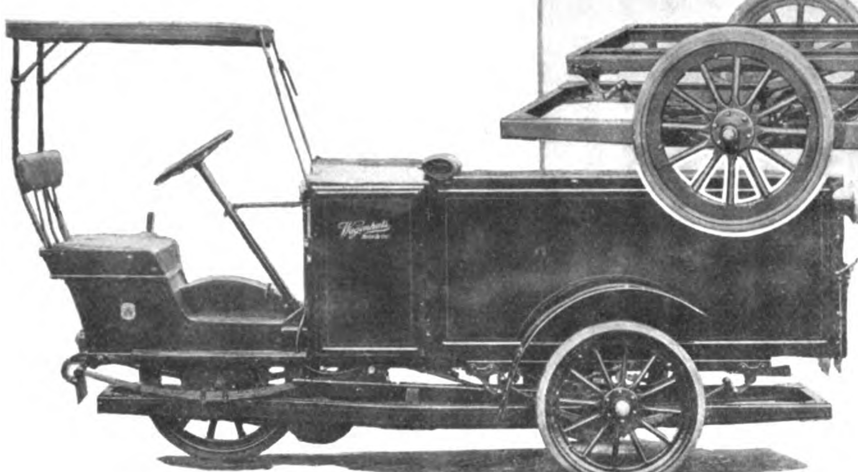
The gasoline tank, located under the driver's seat, has a capacity of 13 gallons.

The wheelbase of the new GMC is 122 inches, while a tread of 56 inches is employed front and rear.

Wagenhals Electric Delivery Car Is Three-Wheel Type



Above—Side view of chassis used in Wagenhals three-wheel light electric delivery car



Left—Electric delivery car with body mounted

AFTER much experimentation, the Wagenhals Motor Co., Detroit, has brought out a three-wheeled light electric delivery car similar in appearance to the gasoline machines of its make. The car has a rated capacity of from 500 to 800 pounds, weighs complete, 1,650 pounds and is to sell for the low figure of $575.

The frame construction used on the new car is the same in design as that on the gasoline type, there being a main frame which carries the axles and drive parts and a sprung subframe to which the body attaches. The two wheels are at the front and turn on spindles to take care of the steering, while the third wheel which does the driving is placed at the rear between the frame rails. This construction is patented.

The electric motor used is a General Electric type, rated at 24 volts and having a speed of 1,600 revolutions per minute. It is placed with its armature shaft transverse and connects through a spur gear to another shaft parallel to the armature shaft. At the other end of this jackshaft there is a sprocket which drives through a 1-inch pitch roller chain to the larger sprocket attached to the driving wheel. The reduction between the motor and jackshaft is 4 to 1 and between jackshaft and rear wheel 2.5 to 1, so that the total reduction between motor and wheel is 10 to 1. Simplicity is gained by the use of one driving wheel as no differential is required.

The battery is small, there being fourteen cells of thirteen plates per cell. The main reason for this small battery equipment is to lower weight. It is intended that two sets of cells be used with each car, one being left on charge all the time while the other is engaged in active service. This is very feasible, due to the extreme ease with which the cells may be slipped in or out.

The battery, however, is good for from 25 to 35 miles per charge, the average speed of the car being 12 miles an hour.

The controller and switches are also very accessible under the drive seat. The controller handle is at the left of the seat and operates a drum type of controller which gives four speeds ahead and two reverse. The steering gear is of the worm and gear type, irreversible. Speedometer, ammeter and voltmeter are placed on the dash.

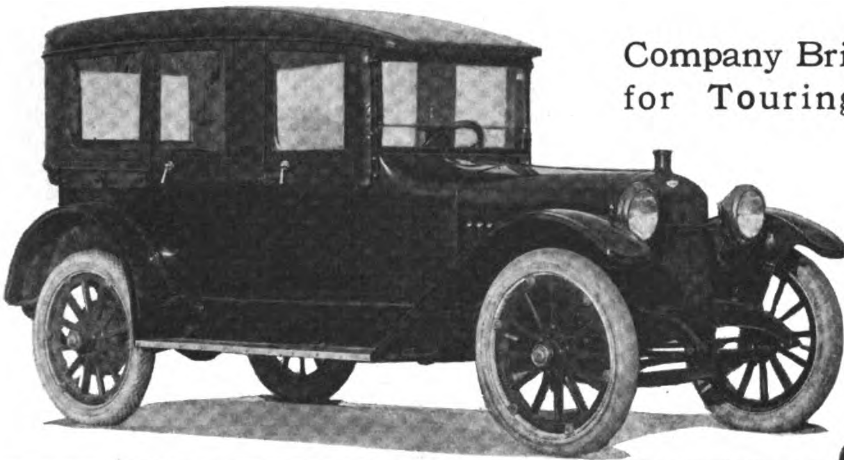
The front wheels carry 28 by 2-inch solid motor tires, while the rear is 30 by 2 1-2, also a solid. Due to the short wheelbase of the car—67 inches—it can be turned in a short space of 24 feet. This makes the car very desirable for traffic maneuvering. Tread is 56 inches.

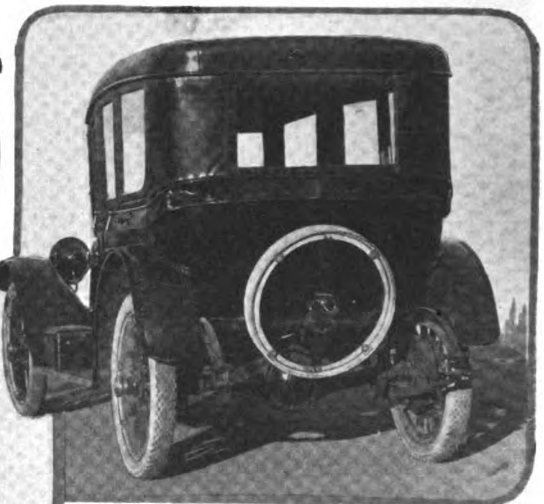
Open or closed bodies are optional. The frame is of wood, but sheet steel covers it. The inside dimensions of the loading space are 70 inches length, 35 inches width and 29 inches height. The open body is furnished with a tarpaulin cover, while a railing runs around the top of the closed job.

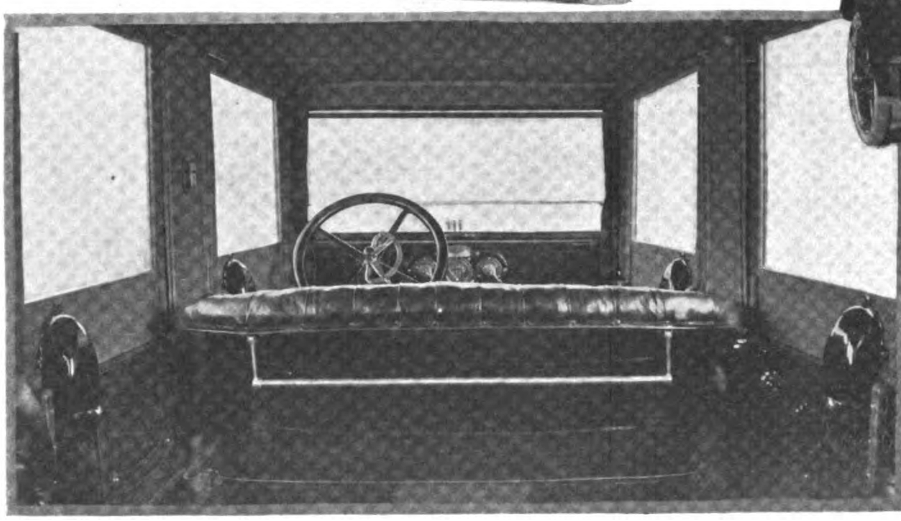
A canopy top is placed over the driver's seat, while side curtains and windshield are also provided. The equipment includes electric lamps and electric horn.

Sedan and Coupé Tops for Hupmobiles

Company Brings Out Removable Types for Touring Cars and Roadsters







Upper left—Hupmobile touring car for 1915 fitted with removable sedan top costing $165

Above—Rear view of touring car fitted with sedan top. Note neat fit

Left—Interior of sedan. The pieces on the doors house the latch levers for the outside handles

REALIZING the demand from a great many automobile owners for tops which will convert their open cars into watertight and storm proof inclosed vehicles for winter driving, the Hupp Motor Car Co., Detroit, has evidenced its progressiveness by bringing out removable sedan and coupé tops for attachment to standard Hupmobile touring cars and roadsters.

These tops, when in place, really convert the open models into closed cars in every sense of the word as will be seen by a glance at the illustrations. The cost is nominal, the coupé top being procurable for $125 and the sedan for $165.

Attachment Is Simple

These tops have been designed so that their attachment is a comparatively simple matter. It is said that two men can easily put one in place. Six points of attachment to the body are provided in the sedan top. The regular folding top irons are pressed into service and iron pieces fixed to the removable top bolt to them. As the touring car has a one-man open top which supports only at the rear and at the windshield, there is, of course, no intermediate side iron on either side of the body, so another form of screw attachment fixes to the body just back of the front doors. A screwdriver and monkey wrench are the only tools required.

In order that the doors in the top will move with the body doors, iron cleats attached to the hinged door sections of the top screw into the body doors, making a rigid construction, moving as a unit when the doors are opened. The latches of the body doors are within the body, so that some means of opening them from outside must be employed. This is accomplished by providing exterior handles in the top doors which run down to the body door latch handles and turn them when the outside handles are turned. The levers taking care of this are housed within the black metal pieces seen at each door in the interior views.

Watertight and Dustproof

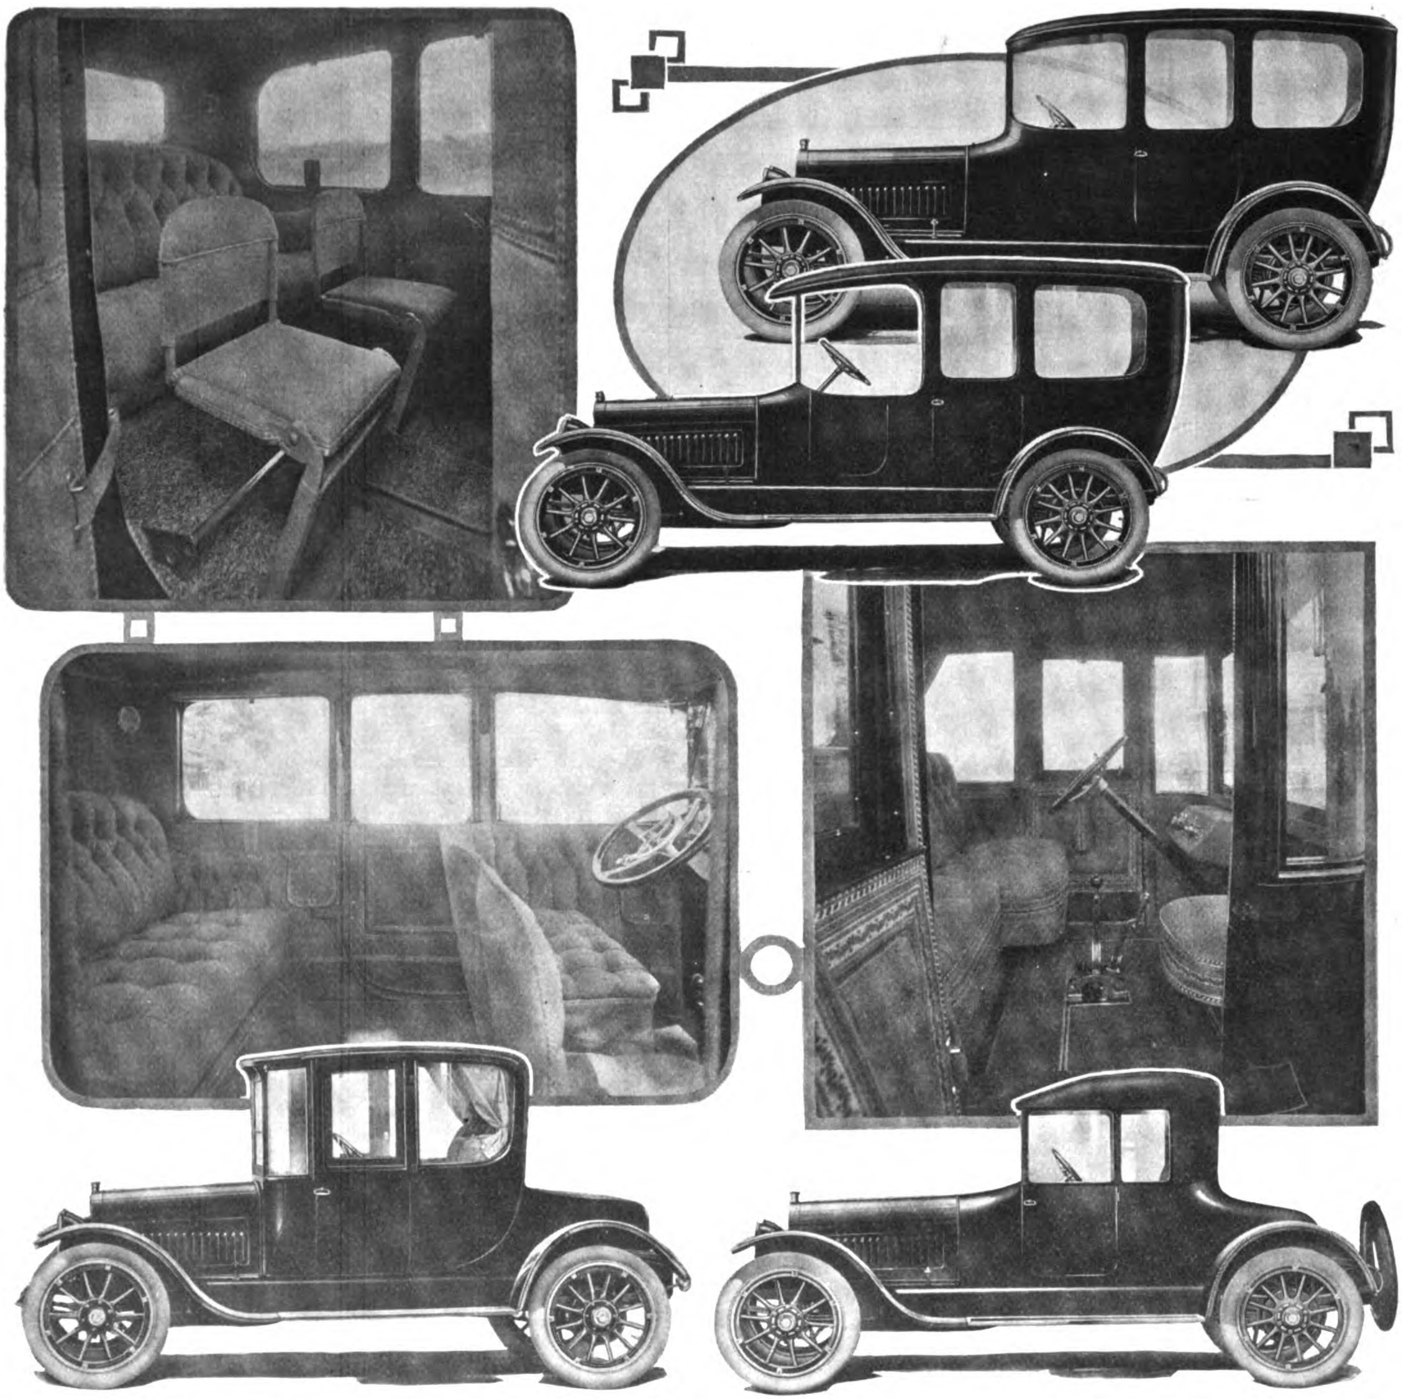
The Hupp company is particularly proud of the way in which the top is built to fit around the windshield so as to render it absolutely watertight and dustproof and to give all the warmth and cosiness of a limousine or coupé built permanently as such.

The equipment of these tops is complete in all details. There is an electric dome light controlled by a switch at the driver's left hand; windows are of coach glass and in the rear compartment of the sedan and in the coupé are adjustable for ventilation. The interior is lined with a fawn-colored material just as many a limousine is finished. In the sedan top, there is a window in each door, and one back of the rear door on either side besides the large rear window. The coupé top has two windows in each side and a rear one also.

These tops are constructed of aluminum and wood fastened with the forged iron supports to insure freedom from rattle.

The weight of the sedan top is 150 pounds and of the coupé 85 pounds, so it is evident that very little is added to the car weight by them.

Chandler Has Four New Closed Bodies



New Chandler body types. The cars illustrated are: Top, sedan; below it, limousine; bottom left, coupé; and bottom right, cabriolet. The interior view at the upper left shows the extra seats in the limousine. At the middle left is the interior of the sedan and at the right interior of the coupé, snowing the seating arrangement for three passengers. Note the rounded glass in the front

CLEVELAND, O., Oct. 24—The Chandler Motor Car Co. is delivering to its dealers throughout the country the new closed body types brought out this year for the first time. The new bodies consist of a cabriolet listed at $1,950, a coupé at $2,200 and a sedan and limousine costing $2,750 each. All these bodies are interchangeable on the standard six-cylinder Chandler chassis and weigh only 100 to 175 pounds more than the ordinary touring body. Aluminum and pressed steel are the materials used in their construction.

With the exception of the cabriolet the bodies are upholstered in gray cloth and Bedford lace and trimming, the cabriolet being finished in hand buffed upholstered leather.

The cabriolet is a three-passenger car, the driver's seat being 18 inches wide with a seat alongside 26 inches in width placed just a little back of the front seat. The coupé is also a three-passenger.

The seat arrangement of the limousine is novel, seven-passengers facing forward with two extra seats having backs when folded into position. By another arrangement these extra seats can be adjusted so that two of the passengers in the tonneau face rearward.

The sedan is a five-passenger model of the owner-driver type. The sedan and limousine rear seats are 47 inches wide and seat three passengers.

One of the features of these bodies is their light weight, the cabriolet weighing 2,950 pounds, the coupé 3,050, the sedan 3,125 and the limousine 3,200. Equipment is very complete on all types.

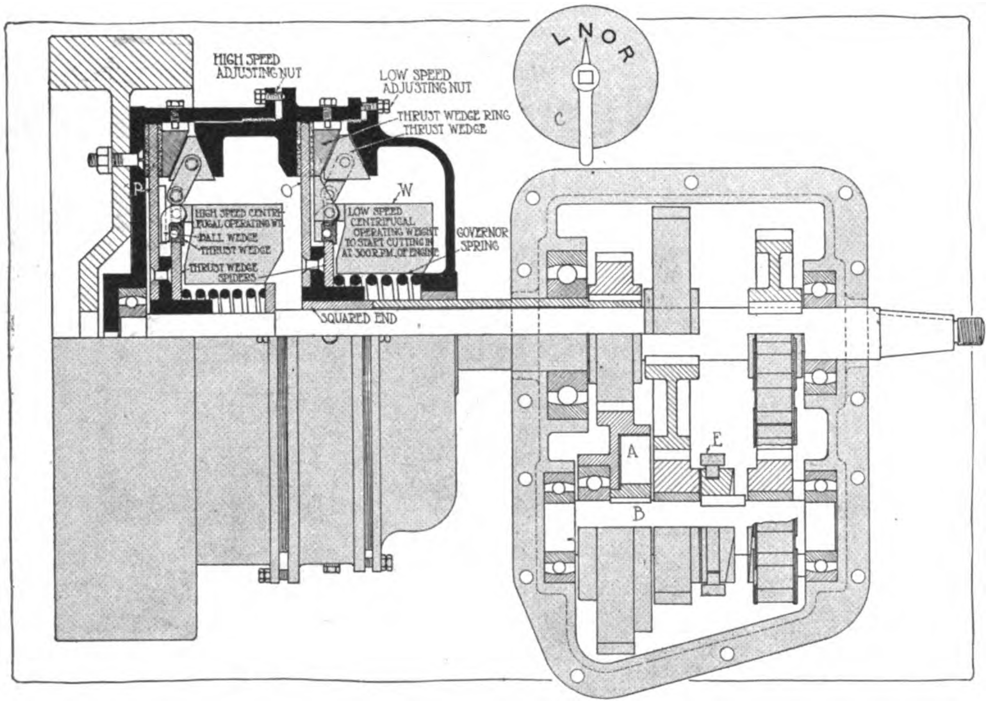


Fig. 1—Sectional view showing operating mechanism of the Zeitler automatic gearbox

Zeitler Gearbox Makes Automatic Changes

Centrifugal Force Employed To Shift Gears From Low to High Speed

AN automatic transmission has been designed by R. S. Zeitler in which manual shifting of gears is intended to be eliminated, the gear reduction of the car being determined by the speed at which it is traveling.

If this gearset works successfully and you are traveling along a level road and suddenly attempt to climb a steep hill, the moment the car slackens in speed to a definite point the gears would shift, giving the reduction which would enable the car to climb the hill without laboring. This is accomplished by centrifugal shifting arrangements.

Each given speed exerts a different amount of centrifugal force on a series of weights mounted in the shifting mechanism. The instant that the speed slackens or increases to such a point that the force exerted on these weights reaches a certain definite point the gears are changed. The gearbox consists, as shown in the accompanying drawings, of multiple single clutches in connection with mutiple sets of gears combined so as to give the desired results. The clutches are the parts that are operated by centrifugal force.

With this gearbox the engine starts without load and at a pre-determined speed of the engine, say at 300 revolutions per minute, the weights would impart a sufficient force to cause a series of thrust wedges to rise against their retaining springs, forcing the disks and friction rings together thus driving the low-speed gears.

Two Separate Shafts

The low gears cause the main shaft to revolve. This shaft in turn rotates the high or next set of clutch weights and, as the car gains speed, the second set of clutches speed up and as they overcome their spring resistance drive the direct shaft, automatically releasing the low gears. As the high speed clutches start to drive, the pinion on that shaft exerts a force on its gear which is on the secondary shaft, driving it faster than it is driven by the low clutches; and, through a slip gear the low set of gears are released in proportion to the amount of engagement of the high clutches. This permits the secondary shaft to move faster than the slip gear is driven. When the car or driveshaft is slowed down to a point where it is necessary to use the low gears, they automatically come into action by means of the slip gear. The low gear clutch is in at the same time as the high clutch.

Referring to the drawings, Fig. 1 gives a sectional view through the shifting mechanism and the gearbox. As the engine starts, the flywheel and the housing, which is shown bolted to it, are carried around with the crankshaft. As the speed increases the weights W rise and the thrust wedge acts against the thrust wedge ring until at a given point, which may be 300 revolutions per minute, the resistance of the governor spring is overcome and the low speed shaft indicated in Fig. 2 commences to be driven through the clutch O. As the speed increases the high speed centrifugal operating weight begins to lift against the high speed governor spring, inserting the wedge against the high speed thrust wedge ring and forcing into engagement the disk clutch P which operates the high speed shaft.

The slip gear consists of an ordinary gear, carried loosely upon the secondary shaft. It is indicated at B, Fig. 1. Part of the interior is so made that a disk can be rotated inside the gear. This disk is keyed to the secondary shaft and has slots cut in it as shown in Fig. 2. In the slots are pawls P. When the driving member, the outside carrying the gear teeth, is rotated by the pinion, the pawls rise and grip the inner surface of the gear as shown at A, Fig. 2. The harder the pull the more the grip as the pawls tend to assume a vertical position, giving a wedge effect. When the secondary shaft is rotated more rapidly than the pinion the pawls are free to lag, but when the reverse is the case, the pawls grip the gear. By this method the gears are always in mesh and the inventor claims that intermediate gears are unnecessary.

May Be Locked in Speed

A small plate is provided for the dash or steering wheel which holds a lever arranged to lock the gearbox in either low, neutral or reverse position. This is accomplished through a dog clutch E, Fig. 1. The length of the gearbox and shifting mechanism on an engine, using a 17-inch flywheel is 21 7-16 inches from the face of the flywheel to the rear end of the gearbox. This is for a two-speed transmission.

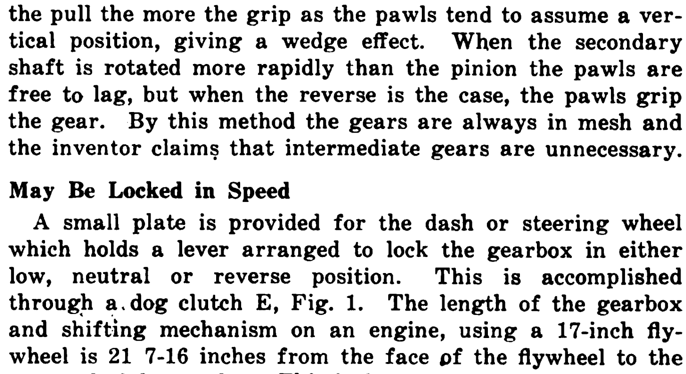

Fig. 2—Clutch engaging mechanism and slip gear with pawls

New Body Styles for White

Chassis Carries Many Improvements—New Starter Position —Wheelbases Longer—All Bodies Lower—New Clutch Brake—Column Control for Lights, Etc.—Other Refinements

MAKING its six-cylinder car only for customers but continuing its two four-cylinder models with an array of chassis improvements and an entire new line of bodies is the passenger car program of the White Co., Cleveland, O., for next year. The prices of the four-cylinder models are slightly higher than for 1914, a fact due to the entirely new line of bodies, embracing a host of de luxe feature coupled with many additions in the line of chassis equipment. The model 30, a five-passenger touring car with complete equipment lists at $2,700 and the model 45 lists at $3,800. There is no list on the six, as it will be made according to custom orders only.

Bodies All Lower

Not since it introduced its gasoline cars has this company carried out such a general line of improvements in the chassis, not to mention the entire new body designs. All models have had the wheelbases lengthened so as to better carry out the streamline body ideals. The bodies are all approximately 3.5 inches lower, in fact the frames are this distance nearer to the road level than heretofore. To do this the clearance has still been retained at 10 inches.

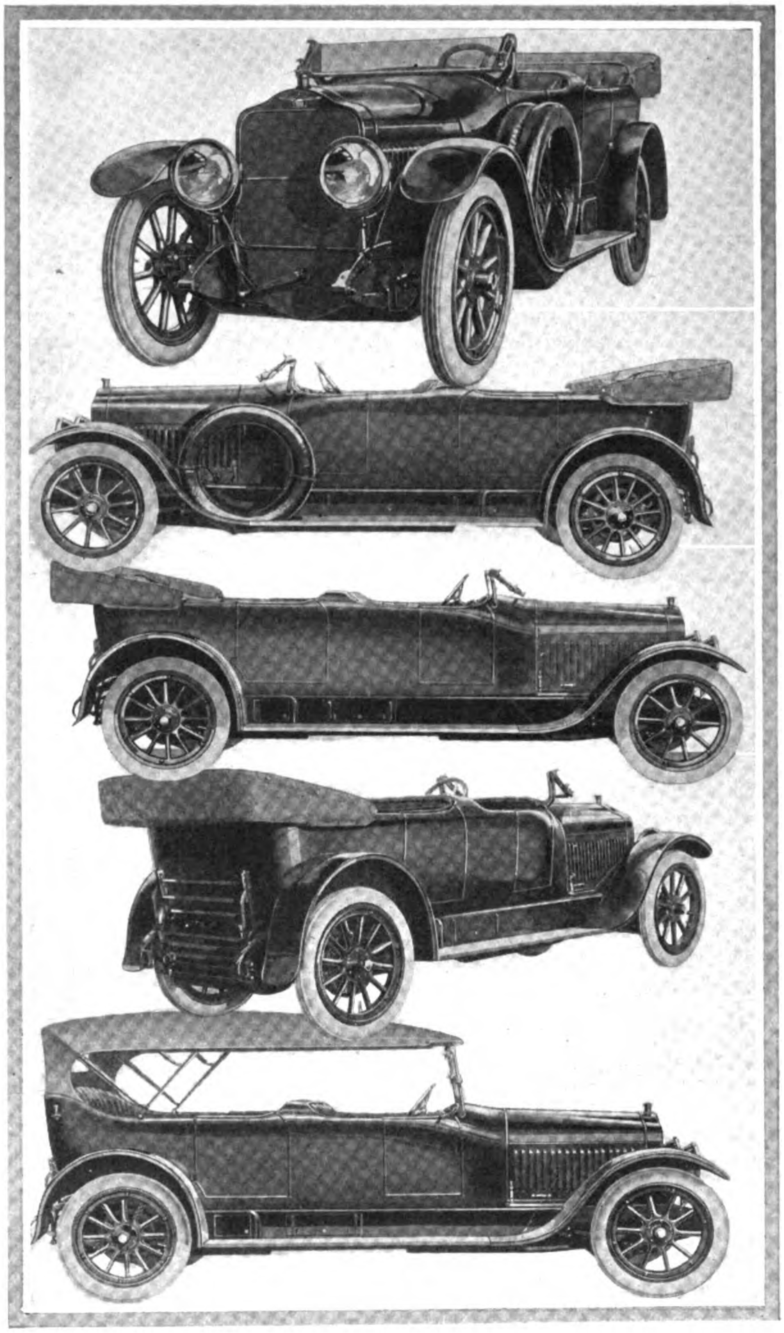
While the general chassis characteristics such as block motors, disk clutches, four-speed gearsets, etc., have been retained without alterations in their major details not a few alterations appear in connections with the parts used with them. For example, the Entz combined motor-generator has been removed from the side of the engine and is located at the right in rear of the gearbox where it is driven by silent chain from the flywheel and a propeller shaft with universal joints.

The gravity and pressure gasoline feed systems of this season have both been abandoned in favor of the Stewart vacuum-gravity system, the gasoline tanks now being carried at the rear, and the carbureters raised high on the side of the motors where they are most accessible and where the intake manifolds are restricted to short elbows.

Control on Steering Column

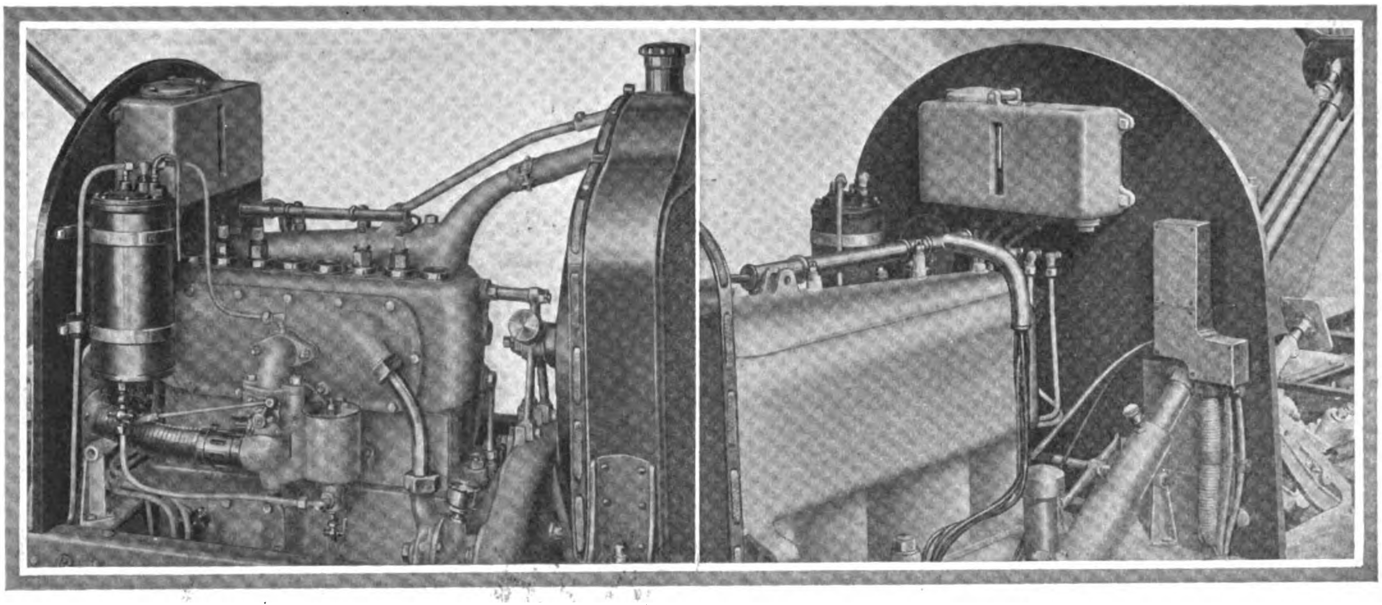
On the steering column below the wheel are mounted all of the lighting, starting and ignition controls, all conveniently grouped on opposite ends of a drum-shaped switch, with the light buttons on one end and starter and ignition control on the opposite end.

Many other minor chassis improvements have been introduced: First comes the use of a new form of clutch brake, described later, and this is followed by an improvement in the clutch release. The radius rods are altered, an equalizer is inserted in the service brake connection, etc.



THE 1915 WHITE STREAMLINE BODIES

At the top is a three-quarter front view of the White model 45 with its streamline body. The radiator is higher than heretofore; the hood is much larger and flares to the cowl. There is not a straight line in the body sides. In the lower illustrations is shown the center cowl back of the front seats. A new form of baggage rack is used in rear. The one-man top adopted for the first time is designed in conformity with the body curves. The windshield is tilted back more than 2 inches



Right and left side of White motor. The Stewart vacuum-gravity gasoline feed tank is seen on the dash. The carbureter is higher. On the dash is the rectangular-shaped oil tank and above the steering column is the junction box for the wiring

On the model 45, the large four, as well as on the six the front axle is dropped between the steering knuckles and the spring seatings in order to lower the frame. The frame is dropped 4.5 inches in front of the rear axle and the rear springs are mounted under the axle. The frames in all models are under 25 inches from the ground.

New Style Bodies

The new line of bodies is most complete embracing practically every design of open and closed lines. In all the hood is immeasurably larger than heretofore so that if you sight a line from the top of the radiator over the top of the cowl, over the back of the front seats and over the rear of the tonneau it would be nearly straight, this line in reality rising very slightly to the back of the tonneau. There is not a straight line in the body side; it is a curve from front to rear with the widest part of the body immediately in rear of the front seats, gradually narrowing fore and aft.

This curve-line effect is further accentuated by the double cowl, namely a cowl constituting the dash and another back of the front seat, this being the first example of a stock American body in which this center cowl is used. Custom-made jobs have used this second cowl which was introduced over a year ago in Europe, but it has not been adopted as a stock body job.

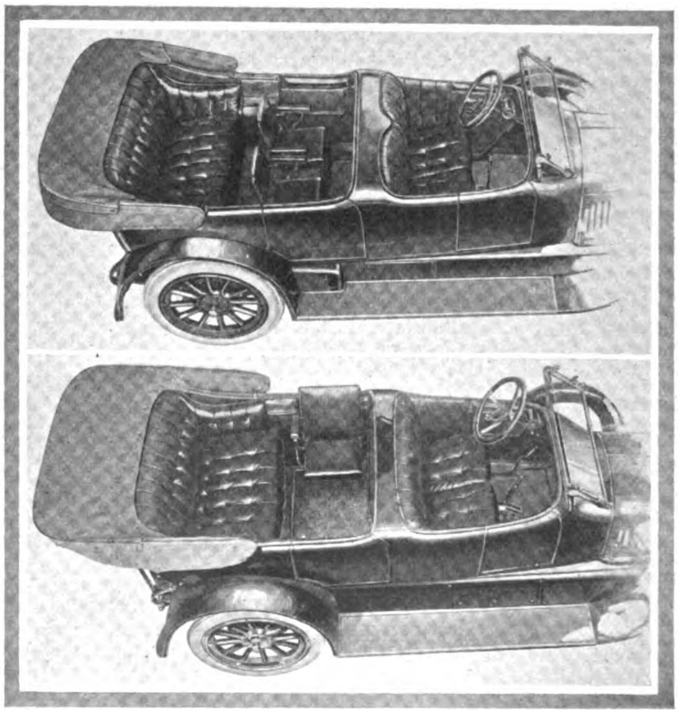
Flare in Hood

Heretofore the White hood has been the same size at the radiator as at the dash, but not so now; it has a pronounced flare. The curve of the cowl is a continuation of that in the hood, namely, in that this cowl curve instead of rising abruptly and being concave is convex so that it leads the eye back to the slightly convex curve of the center cowl, and this in turn leads the eye to the curve or line at the back of the tonneau. Thus do the body curves not lead the eye away from the body, as is so often the case, but rather lead the eye into the body at a point nearer the rear.

Considering a cross section of the body of a touring car taken immediately in rear of the front seats, the body is narrower at the top of the sides than at the floor. To this construction the expression tumble-in has been applied by several European makers. The designer has introduced this additional body curve in order to carry out the streamline effect and at the same time it gives a wide seat and gives the impression of the passengers sitting in the body, scarcely an evidence of the seat formation appearing above the body lines.

All bodies are considerably lower than heretofore, due to dropping the rear end of the frame 4 inches on the large four model 45 and also on the six, whereas on the small four or model 30 this has not been done. On these two models the three-quarter rear springs are now mounted under the axle instead of over it. The forward end of the chassis, by a new design of front axle, is heavily dropped between the steering knuckle and the spring seating, the drop here being so great that in order to give the front end of the crankcase clearance the center of the axle curves slightly forward. The net result is that the frame is less than 25 inches from the ground and yet the mud apron clearance is 10 inches.

Still further has this low streamline effect been accomplished in all models by the lengthening of the wheelbase in all models, thus in the 30 it has been increased from 110 to 115 inches; in the 45 from 124 to 132 3-4; and in the six from 132 to 140 3-4.



On top is shown the seating arrangement in the seven-passenger body and at the bottom the auxiliary seat in White model 30

Several other factors enter into the general body makeup to carry out the conception of the designer. The steering posts are tilted at an angle of 37 instead of 45 degrees and on the runabouts the rake is still further increased to 33 degrees.

The low glass windshield rests directly on the cowl, no filler board being used, and it tilts backwards 2 1-4 inches.

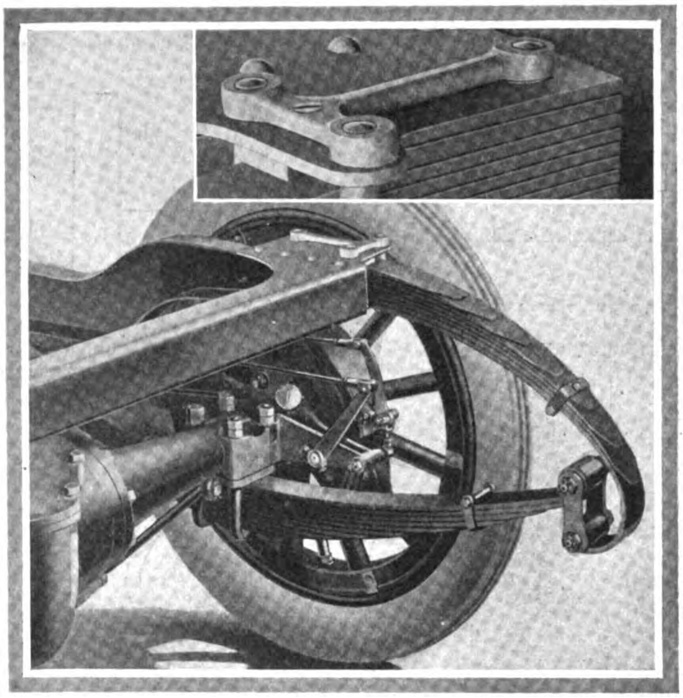
The one-man top equipment, used for the first time, sits inside the body instead of outside of it and its top line is a curve which conforms with the body proportions.

Front and rear fenders are crowned, an innovation with this company, the amount of arch being 2.5 inches for a fender width of 13 inches on the larger models.

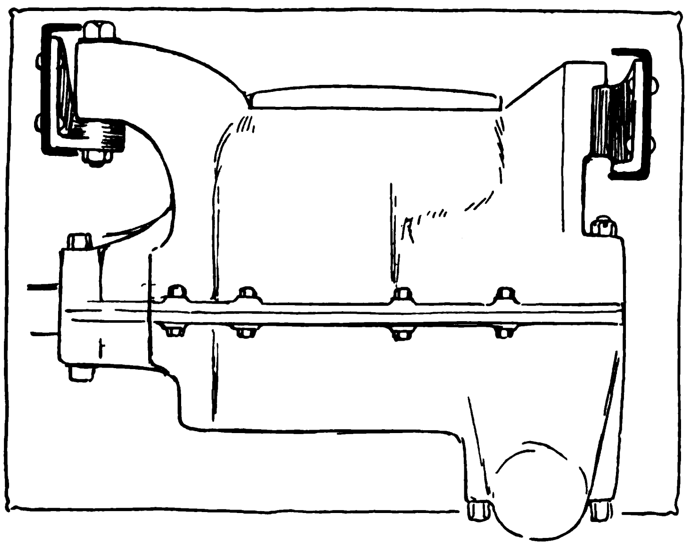
Internally this new line of bodies is replete with improvements, some of which perhaps can be placed in the column of innovations. The upholstery is tufted in parallel ridges in contrast with the diamond pattern; front and rear seat cushions rest on the floor and both are slightly tilted for comfort. To accomplish this the gasoline tank on all models is at the rear and the tool boxes are on either side of the chassis within the apron extending from the frame to the inner edge of the running board, with access to them through small doors.

Low Auxiliary Seats

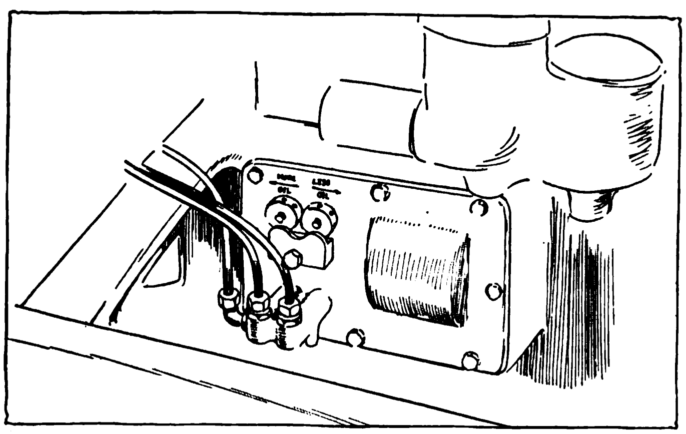
The folding tonneau seats are sunk into the floor 2 3-4 inches so that the passengers on them are on the same level as those on the rear seats instead of being higher. These seats fold forward and rest vertically in a compartment in rear of the front seats. When open, in the sitting position, they are locked by a spring catch. On model 30, a five-passenger car, an extra detachable seat is furnished which allows the passenger sitting sidewise, and this seat folds into a compartment back of the front seats.



On White models 45 and six the three-quarter rear spring is now under the axle and on top the spring attaches to the frame by bolts which can be removed from the under side so as to allow of removing the spring without interfering with the body



Showing support fore and aft of White gearbox on brackets in the frame cross members so that the over-all length of the box will allow of its being lifted directly out or dropped



On the outside of the White crankcase are oil adjustments for the pump. The adjustments are round nuts, which can be turned by a punch for adjustments

No Upholstery above Parapets

Several additional body details deserve noting such as no upholstery appearing above the body lines; in the rear is a new design of trunk rack which can be opened or closed by one movement, either a pull or push; and this rack is supported by the gasoline tank protecting guard, a spring catch holding the rack locked in the closed position. Two spare tires can be carried in the left running board where they are countersunk in the running board and front fender; and beneath the center cowl on the 45 and the six are two package compartments with a clock mounted flush between them. Below these compartments is the space to receive the auxiliary seats.

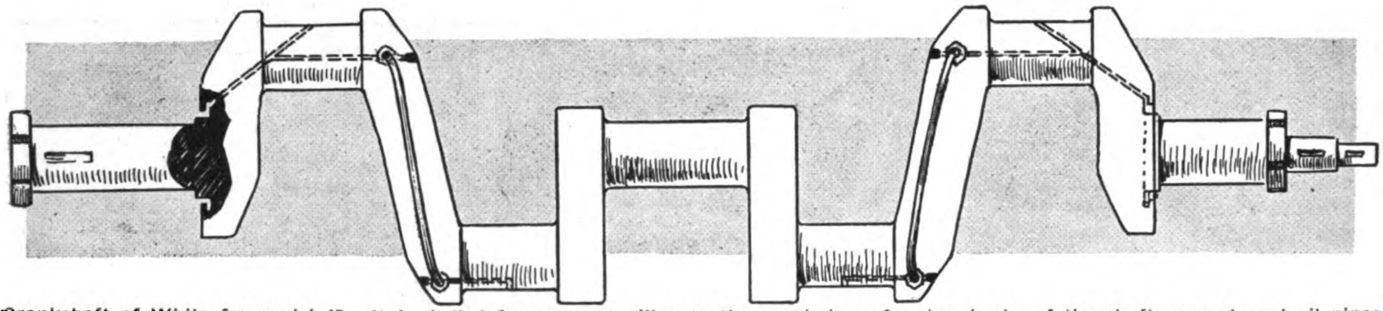
Lastly the staid black has been ruled out of the category of color options furnished as stock, and now the purchaser can take his choice of White special maroon, White special grey, Cleveland grey, Brewster green and Cobalt blue.

Motor Backbone Unaltered

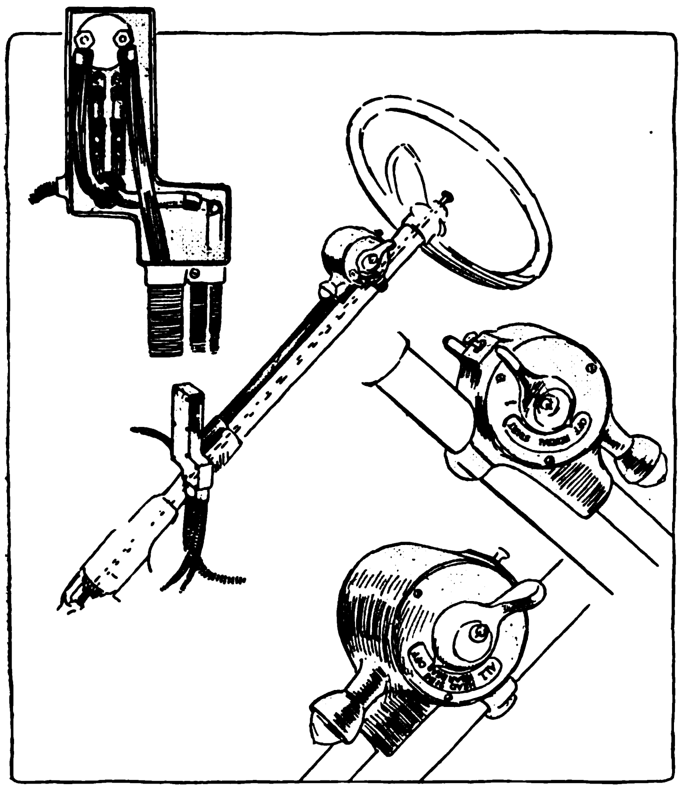
The motors remain practically the same, excepting that many changes have been made in their components. Moving the Entz motor-generator to the rear has advantages. This unit is now driven by silent chain from the flywheel and thence by short shaft with universal joints. In its present position it is immediately ahead of the battery, swung in a cradle from cross members of the frame.

Accessibility Improved

In this new position it leaves the motor more accessible, adds somewhat to the cooling of the motors in that there is less restriction to the air currents and it also takes its drive off the timing gears. It is geared 2.6 to 1 with the crankshaft and the motor-generator unit is 20 pounds lighter than this year. By changing its winding somewhat it has been given



Crankshaft of White for model 45. It is drilled for pressure oiling to the crankpins. On the cheeks of the shaft are external oil pipes leading from the main bearings to the crankpins



Control parts on steering post of 1915 White cars

different electrical characteristics so that it begins charging at a car speed of 7 miles per hour and its maximum charging rate is reduced practically one-third, to avoid overcharging at continuous sustained speeds. There are no current regulating parts inserted between this motor-generator and the battery excepting a small dash indicator to show when it is charging or discharging.

21-Volt Lamps

Twenty-one volt lamps are used throughout in the car, that is for the two headlights, tail, dash and small lights in the headlights. These headlight bulbs are now in multiple, rather than in series so that now if one burns out the opposite one does not go out. The double wire system is used. Wiring in general in the car has been vastly improved, all wires are carried in metal conduits and on the forward side of the dash; immediately above where the steering column pierces it is a junction box containing the fuses.

The oil reservoir has been removed from the engine base and is now a separate compartment on the forward face of the dash below the bonnet. The plunger type of pump remains incorporated within the crankcase at the right rear with external adjustments. The oil is fed to the crankshaft bearings and thence through the drilled crankshaft to the crankpin bearings. Instead of conducting the oil through the long cheeks of the crankshaft between the first and second and third and fourth crankpins use is made of external oil pipes which arc outward in order that centrifugal force will be utilized to the greatest extent. A splash level is maintained within the case.

Installing the Stewart vacuum-gravity gasoline feed system brings the fuel to the special vertical tank on the front face of the dash at the right where it is warmed by the motor. From this tank the fuel feeds by gravity. The White carbureter has been generally improved. Using the Stewart gravity system allows of carrying the carbureter higher than formerly. It is now well up on the side of the engine, with a most abbreviated elbow serving as a manifold. This carbureter designed along Claudel-Hobson lines, is without moving parts or springs of any nature.

Arc Clutch Brake

The new form of clutch brake, to prevent clutch spinning when shifting gears is an arc-shaped brake with a fabric facing bearing on a small drum on the clutch shaft. One end of the arc band is hinged to the frame and the other has a linkage with a short arm on the clutch operating shaft.

Another clutch improvement is in the disengaging collar which is now a cone-shaped member against which bear two rollers carried in the bracket on the cross shaft, the rollers being at an angle to bear directly on the cone referred to. Grease cups are provided.

The radius rod construction has been changed and instead of the forward end of these rods attaching to a part of the spring bracket they now have a ball-and-socket connection with a bracket attached to the under side of the frame. They are longer than heretofore and their attachment at the rear to the axle on the 45 and the six is altered, due to the underhung springs. Here the axle pad is extended forward and inwards forming a ball ending which enters the socket in the radius rod, a connection similar to that employed in steering connections.

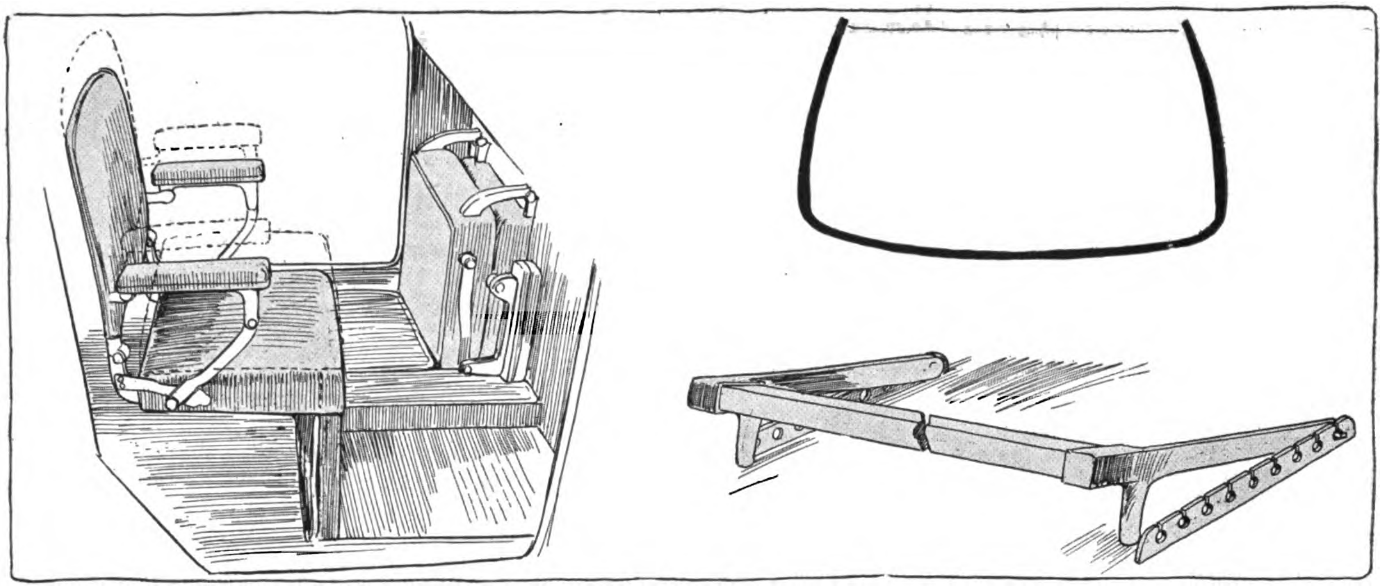
Column Control

In the new system of control parts mounted on the steering column there is on one end a short handle controlling the starter, with three positions, start, neutral and off and on the opposite end a similar handle controlling the various lights and having a position at one end for all the lights being on and an opposite position for all off, with intermediate positions for lights as needed. A Yale lock is in combination with each handle. The under side of this switch cylinder carries a small light which shows on the dash oil gauge and speedometer.

Braking has been improved in that there is now an equalizer in the service brake connections as well as in the emergency ones, heretofore the emergency set being only so provided.

Accessible Springs

An improvement in connection with the rear spring attachment on the 45 and six is that where the spring attaches to the frame there is an extension of the frame cross mem-



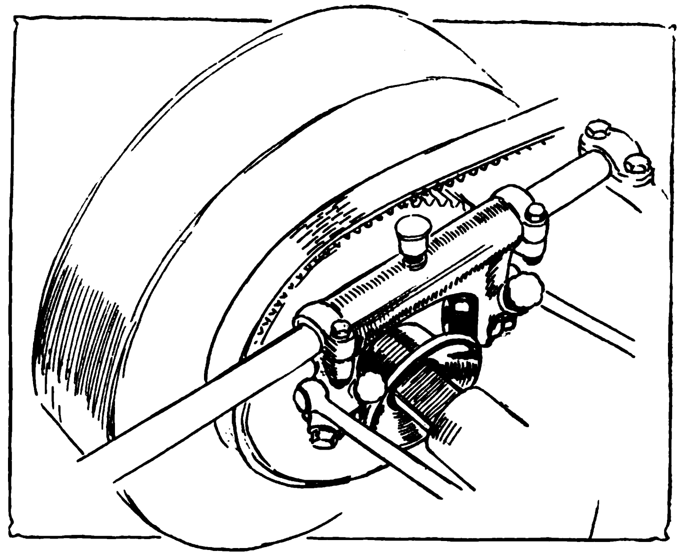
Auxiliary tonneau seats in White, showing them countersunk into floor, and also how they fold into position. On top is cross-section of White body in rear of front seat and underneath adjustable foot rest for tonneau of all models

ber under which the spring fits. The clip bolts thread into this plate and have not nuts on their upper ends, so that now the spring can be removed without having to raise the body to get at the nuts on the clips.

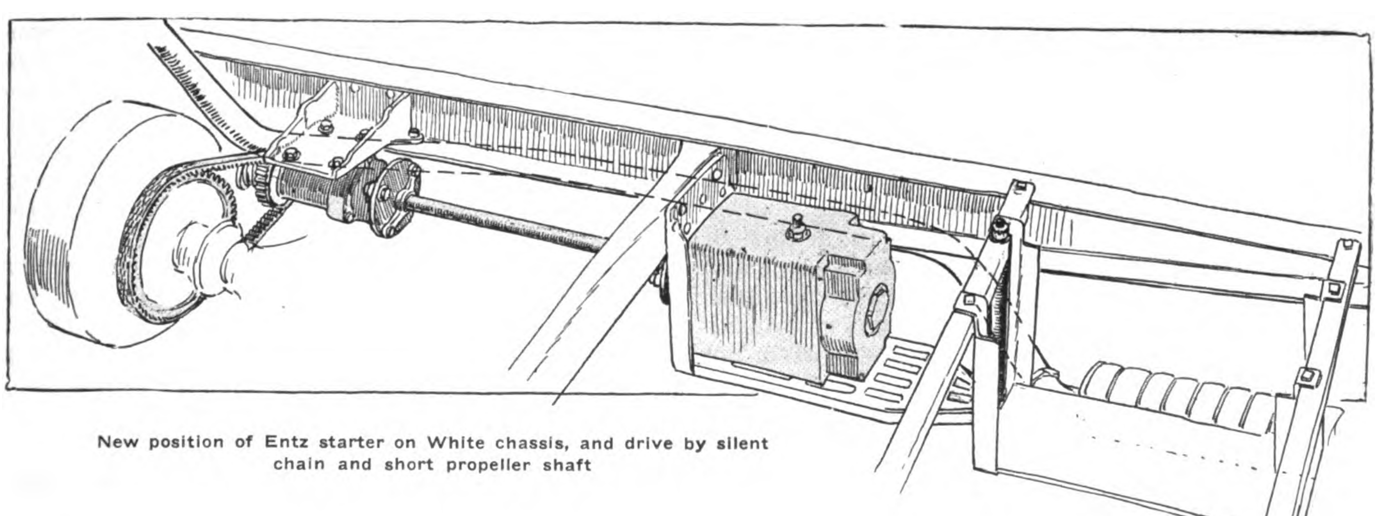
The single ignition system used since its adoption of the gasoline motor is continued, the magneto alone being relied upon. It is entirely separate from the starting and lighting system.

On model 30 are 32 by 4-inch tires in contrast with 34 inches sizes for 1914.

Motor sizes remain as formerly and are: On model 30 they are 3 3-4 by 5 1-8; on model 45 they are 4.25 by 6 3-8; and on the six they are 4.25 by 5.75. The L-type block casting with integral intake, exhaust and water manifolds is continued; valve operating parts are inclosed and the general motor characteristics unaltered excepting as already referred to. The four-speed gearbox, mounted as a separate unit amidship is continued. On model 30 direct is on third with fourth gear a stepped-up indirect. On the other two models fourth is direct. Drive from the gearbox is through a propeller shaft with two universal joints to the White design of axle carrying its two sets of brakes one internal, the other external. Steering is on the left on all models with the gearshift lever in the center for right hand operation and the emergency brake lever at the left for left hand operation. The ball end on the gearshift lever which was standard for 1914 has been discontinued.



White clutch, showing cone-shaped release collar. Another clutch improvement is a new form of clutch brake adopted to prevent the clutch spinning when the driver is shifting gears. The new brake is arc-shaped and is provided with a fabric facing bearing on a small drum on the clutch shaft. One end of the arc band is hinged to the frame and the other has a linkage with a short arm on the clutch-operating shaft. Note the silent chain drive for the Entz motor generator



New position of Entz starter on White chassis, and drive by silent chain and short propeller shaft

Profits of War

TO this date the American automobile industry is profiting substantially by the European war, careful estimates placing the sale of American motor trucks to belligerent and non-belligerent countries at close to the 3,000 mark. France has been the biggest buyer, taking considerably more than 50 per cent. of this output, and Russia, England, Greece and some other European nations have been making purchases. Those American builders are profiting most who were best ready to take care of immediate shipments, and who were further able to guarantee quick deliveries on large quantities of vehicles.

It is not ethical to refer to business that is thrust into your hand due to the misfortunes of others and no thought of boasting is included herein; but the fact remains that America has had placed squarely in her lap the greatest opportunity in history of demonstrating her wares in the eyes of Europe and the entire world. Heretofore Europe has looked with more or less misgiving on our motor trucks, considering them quite too heavy and falling short in not a few other respects. The necessity brought on by the war is bringing American trucks side by side with those of Europe and the stamina of them will be watched with particular interest during the next 6 months.

America has for years boasted that her passenger cars were built to stand up on rough American roads, facing daily conditions that might test to the death not a few of the European cars. The same has been said about our trucks. The time of test has arrived. It is no silk-stocking test, but the test supreme. If American trucks make good it will be the greatest advertisement that the motor industry in this country has ever received and one which will mean more to the development of that industry than anything heretofore accomplished.

Wear

SOME weeks ago attention was directed through these columns to the vital points in truck construction that foreign buyers took into consideration in making purchases for war purposes.

At that time it was outlined that the ability of the truck to withstand wear was looked upon as one of the cardinal, if not the primary consideration. The truck that would not wear was not considered. Some trucks were passed up because their weight was such that it in itself imposed a needless load on the vehicle, a load which was doing its part to wear out the truck rather than it being worn out by a useful load.

The old story of the chain being as strong as its weakest link is most applicable to this aspect of wear in motor trucks, whether such trucks are intended for war purposes or not. The real strength of the truck is that of its weakest part. Further, the standard of wear in the truck is that of the part that will wear first. It is a poorly balanced truck that has parts placed in one part of it that will wear for 10 years or longer and to put other parts in that will need replacing in 3 months or 6 months at the longest. The truck must be balanced, in a word, the weakest link idea should permeate every part of the vehicle.

In the zone of war activities the truck that for any reason whatsoever drops out of the convoy is a most distressing factor. It is sufficiently bad to have a truck which you are using in your business incapacitated for a day. When it stops you can secure others to do its work or hire horses. In war it is different. The vehicle in the convoy that falls out is generally lost. It is pulled to the roadside, more often into the ditch, in order that the road be left open for the remainder of the convoy and the other arms of the service. If the part worn or broken can be adjusted or replaced in a short period of time there is hope that the vehicle can be saved, but otherwise it becomes one of the many unrepaired and finally abandoned.

Wear, or the ability to wear, is a most important factor in truck life. It is also very important that where parts are subjected to great stresses and wear that adequate provisions be made for the adjustment of them. It is an error in design where such adjustments are overlooked. It is an equal error if accessibility is not a prime consideration in connection with parts subjected to great wear, or in danger of being broken.

Claims $700 Electric Impossible at Present

Animated Discussion of Field for Low-Priced Vehicles Marks Close of E. V. A. A. Convention—Session a Success

PHILADELPHIA, PA., Oct. 24—The closing of the Fifth Annual Convention of the Electric Vehicle Assn. of America was animated by the discussion between electric vehicle manufacturers and central station interests on the possibility of the low-priced electric, namely, a passenger vehicle selling at from $500 to $700 and manufactured in large quantities.

T. L. Jones, a representative of the central station interests in Brooklyn, opened the question in his address when he asked, what was being done to distribute information on electric vehicles throughout the country. "The passenger electric vehicle is too high priced," began Mr. Jones. "The only reason why central station companies are not using such vehicles is the high initial cost. In Detroit every central station salesman uses a gasoline car. If the electric vehicle manufacturers will go to the central station people with a $700 electric car they will get enough orders to make its manufacture possible. Today the electric passenger vehicle is for the luxurious classes. According to the registrations of July 1, 1914, 80 per cent. of the gasoline passenger cars had a selling price under $2,000, whereas 85 per cent. of the passenger electrics sold in excess of this price."

Mr. Jones contended that the sale of electric vehicles must be pushed by those people who profit by the sales, and the four people who profit by the sales are the manufacturers of cars, the manufacturers of batteries, the manufacturers of such accessories as motors, tires, etc., and lastly the central station or electric power producing companies.

Lack of Mileage a Drawback

Mr. Jones believes that the lack of mileage is a drawback to the present extended sale of the electric passenger vehicle. "The maker who says he has a 120-mile car," continued Mr. Jones, "has not such a vehicle. He may have it on a glass road and at a certain temperature, but not under normal traveling conditions. Real facts will be more effective than glaring statements."

Continuing Mr. Jones criticised the battery people on the ground that during the last 2 years there has been little progress made in chemical research, although there has been much progress made in the mechanical details of the battery. He spoke of the work the central station interests are doing in Brooklyn by distributing cards to electric truck makers, which enables them to stop at other depots for a boosting charge and secure same at the regular rate. In Brooklyn they are working to have decorative lamp-posts fitted with charging plugs so that the scope of the electrics can be thereby increased.

The gauntlet hurled into the ring on the $700 electric was immediately taken up by George H. Kelly, of the Baker Motor Vehicle Co., Cleveland, who, voicing the views of a part of the electric vehicle manufacturers, contended that it is practically impossible to build a $700 passenger electric vehicle at the present moment. Mr. Kelly believes there is no demand for such a low-priced vehicle at the present time, but rather that the demand is for a good-looking car with a mileage radius from 70 to 80 for battery charge. With a $700 electric this radius would be approximately 30 miles, and the average speed of the vehicle lower than at present.

Concerning the possibility of central stations buying cheap electrics in large quantities, Mr. Kelly cited an experiment made some years ago in which a canvass was made of practically 1,700 different central station people as to the market for an electric to sell at $1,200 and which would have a good mileage radius as well as an adequate speed. There were not enough prospects coming from the central station people to warrant the necessary expenditure for the production of such a vehicle.

"The low-priced electric," Mr. Kelly went on to state, "is yet in the future, and its coming depends on the 6,000 different central stations in the country. If they can get together and place sufficient orders so that such vehicles can be manufactured on a quantity basis, it will be possible to produce such a car, and not until then."

The discussion pro and con on the $700 electric was continued for some time, in fact it was the major discussion of the convention.

"A further cost in the electric car," said Mr. Kelly, "is the mechanical work that must be looked after and which is not a factor in the low-priced gasoline car. A loss of 1 horsepower in a gasoline car is almost a negligible factor, but is a big factor in an electric. Because of this the cheap electric must be a well-built vehicle eliminating friction losses in order to conserve electric current.

"Two big arguments for electric vehicles are long life and low cost of upkeep, and these cannot be secured with cheap construction. After all, first cost is not the biggest factor, particularly if you are going to pay one-half the original cost for fuel to operate the car with during the first 20,000 miles."

According to J. C. Bartlett, a Philadelphia dealer and garageman who handles electrics, there is not any demand for the cheap electric and it cannot be manufactured and marketed for $700. He referred to certain movements in the electric passenger field some years ago where efforts were made to market vehicles much under the present prices, and that these practically ended in failure. The public demands a luxurious type of car with power and mileage.

S.A.E. Standards Committee Meets Nov. 17-19

NEW YORK CITY, Oct. 27—The Standards Committee of the Society of Automobile Engineers will hold a 3-day convention in this city, November 17-19. The meeting will be held in the offices of the association.

Reports of the divisions will be submitted and considered at the meeting which will probably be attended by the entire membership of the Committee, consisting of 142 members.

A brief outline of the work and plans of the different divisions was given in THE AUTOMOBILE for October 1.

King Has Eight-Cylinder Car Under $1,500

NEW YORK CITY, Oct. 26—The King Motor Car Co., Detroit, Mich., has announced that it will build an eight-cylinder car for 1915, to sell at something less than $1,500 complete, as a five-passenger vehicle. It will have a conventional type of eight-cylinder V-motor, with an S. A. E. rating of between 40 and 45 horsepower, and with a wheelbase of 113 inches.

It was known some months ago that the King company, as well as several other concerns, was deeply interested in the eight-cylinder movement, and had purchased a well-known make of car using this type of motor. The company is prepared to guarantee deliveries on this model after December 30. Its present four-cylinder car will be continued as a regular stock model.

Owen To Develop Weidely Motor

INDIANAPOLIS, IND., Oct. 27—Frank E. Smith, receiver for the Premier Motor Mfg. Co. has been authorized by the U. S. Court to borrow $10,000 to carry on the business under the present receivership and the court has further confirmed the contract which Receiver Smith has made with R. M. Owen, New York City, George A. Weidely, Premier engineer, and H. O. Smith of the Premier company, by which Mr. Owen agrees to spend whatever money is necessary for further experimental work in developing the Weidely motor which the Premier company has been marketing this year. A further part of this contract is that the receiver is to deliver to Messrs. Owen, Weidely and Smith, the patterns and core boxes, of the motor. Still further, according to the contract, the receiver sells certain parts of the motor to these three people and the receiver and his successors in return have the right to use the motor in its present or perfected form.

R. M. Owen, president of the R. M. Owen Co., New York City, and also a stockholder in the Entz Motor Corp., New York City, controls the Entz electric transmission, and it has been known that he has, during the past summer, been developing this transmission and chassis fitted with the Weidely motor.

CHICAGO, ILL., Oct. 24—The Stewart-Warner Speedometer Corp., has declared the regular quarterly dividends of 1 3-4 per cent. on the preferred and of 1 1-2 per cent. on the common stocks, both payable November 2. The books closed October 24 and re-open November 2.

Harroun Made Chief

Heads Maxwell Engineers—Redden Leaves Sales Force—Rubber Brisk in London—Monarch Lowers Price

DETROIT, MICH., Oct. 27—Ray Harroun, the racing driver, who designed and built the Maxwell cars which made such a good showing in this year's races, has been made Chief Engineer of the Maxwell Motor Co. The Maxwell engineering department has heretofore been jointly headed by R. E. Benner and Wm. Kelley, the latter having had much to do with the design of the motors. Benner has severed his connection with the company, while Kelley continues as assistant to Harroun. During the last few years Harroun has been active in carburetion, having designed the Harroun kerosene carbureter with which one of the Maxwell racers is equipped.

Another Maxwell change is the resignation of C. F. Redden as general sales manager. C. E. Stebbins, former assistant sales manager, has succeeded him.

DETROIT, MICH., Oct. 26—The Maxwell Motor Co., this city, will have six zones, instead of four, as heretofore. Each zone, or division of territory, will have its own supervisor and one publicity supervisor. The zone supervisors are the direct medium between factory and dealer, while under the supervisor are the district salesmen, acting as his lieutenants.

Good Demand for Rubber in London Market

LONDON, ENGLAND, Oct. 17—It is expected that the price of rubber will be fully maintained at over 50 cents a pound for at least the next 6 months. The requirements of the Allied Armies are sufficient to absorb nearly the whole of the plantation rubber production for that period.

Before long the French and British military authorities will need to refit tires on most of the 250,000 motor transport vehicles said to be in use, and there is also a big demand for waterproof ground sheets for the troops, rubber boots, etc.

At the commencement of the war, Germany made great efforts to secure additional supplies of rubber, but the commodity was declared contraband of war by the British Government, and Great Britain practically controls the plantation rubber industry while the Brazilian shipments of wild rubber are very small at present, owing to the commercial depression in that country.

Monarch Six for 1915 Sells at $1,250

DETROIT, MICH., Oct. 27—The Monarch Motor Car Co. will manufacture a six-cylinder car for 1915 which is on the same lines as the 1914 product but at a lower price. The 1915 car will sell at $1,250 or $150 less than in 1914.

U. S. L. Committee Has 55% of Preferred

BUFFALO, N. Y., Oct. 27—The protective committee of the United States Light and Heating Co. announces that it now has on deposit approximately $1,400,000 par value of the $2,500,000 preferred stock outstanding, which is equal to about 55 per cent. of the issue and expects that within a short time additional deposits will bring the amount up to 75 per cent. So far about $3,500,000 par value of the $14,000,000 common stock outstanding has been deposited, this amount being about 25 per cent. of the junior issue. It is expected that the committee will begin to work out a plan of reorganization and an announcement of some kind on this plan can be expected in the near future.

Voiturette Receiver Not to Sell Cars Separately

DETROIT, MICH., Oct. 26—In THE AUTOMOBILE for October 15, page 738, it was stated in the news item concerning the bankrupt American Voiturette Co., that the 375 finished and unfinished Car-Nation cars will be offered for sale at a uniform price of $250, while the Keeton cars will be offered at $1,000. This information was rather misleading as it was a tentative figure proposed in case there should be a sacrifice sale of the whole lot of cars to one purchaser. It never was the intention of the receiver, the Detroit Trust Co., to have the cars sold individually to the public.

DETROIT, MICH., Oct. 26—A hearing has been set for November 9 in the United States District Court, when Judge Tuttle will decide whether the offer of $100,000 cash made by the Samuel L. Winternitz Co., Chicago, for the property of the American Voiturette Co., exclusive of the real estate, accounts, notes and cash, should be accepted. All creditors should attend the hearing.

De Laski & Thropp Co. Wins Patent Suit

TRENTON, N. J., Oct. 27—The de Laski & Thropp Circular Woven Tire Co., Trenton, N. J., was awarded the decision in the U. S. District Court here last week in its suit against the William R. Thropp & Sons Co., of Trenton. The decision sustains the validity of certain of the claims of United States patent No. 1,011,450, dated December 12, 1911, which covers the tire wrapping machine put out by this company and holds the machines manufactured by the defendant to be infringements.

Attorneys for William R. Thropp & Sons Co. state that an appeal will be filed at once.

New Crow Touring Car Sells at $745

ELKHART, IND., Oct. 26—The Crow Motor Car Co., Elkhart, Ind., has recently completed a five-passenger, 20 horsepower touring car to be sold with full electrical equipment at a list price of not to exceed $745.

This latest addition will be known as the Crow Elk-Hart, Jr. This car has streamline body, oval-front radiator, full-floating rear axle, three-speed selective transmission, dry-plate multiple disk clutch, center control, Gray & Davis electric generator and starter, electric lights and dimmer, 30-inch wheels, 3 1-2-inch tires, 101-inch wheelbase, drop-forged front axle, U-shaped doors and three-point suspension for the motor. The crankcase, water manifolds and gearbox are of aluminum.

The car is finished in navy blue with nickel trimming. It will have excellent upholstering, tilted seats, mohair top, Stewart speedometer and the gasoline tank will be built in the cowl with filler cap under the hood. The clear vision ventilating windshield is an integral part of the body, preventing it from working loose. The back of the front seat will be leather covered. With full equipment this new model weighs 1,575 pounds.

ST. LOUIS, MO., Oct. 24—A bill was passed in the Municipal Assembly here this week giving doctors the right-of-way on public streets with their automobiles and permits them to pass any procession or assemblage in the streets. Previously the fire department equipment, ambulances, U. S. mail wagons, police patrols and street railway repair wagons were the only ones favored by the right-of-way law.

Mirrors on All Motor Trucks in N. J.

NEWARK, N. J., Oct. 27—Beginning with January 1, 1915, all motor trucks in New Jersey must be fitted with mirrors enabling the drivers to see the road back of the truck. The rule was made necessary by the protected position of the driver, who is unable to see behind and to realize when another vehicle passes from the rear.

Crown Co. Officials Indicted for Mail Fraud

LOUISVILLE, KY., Oct. 25—C. H. Lambert, and his son A. B. Lambert, have been indicted in the Federal Court here, being charged with using the United States mail to defraud, the action being in connection with the Crown Motor Car Co., which has recently been succeeded by the Hercules Motor Car Co., with the former concern of which the Lamberts were officers. Yesterday, they made cash bonds of $4,000 each.

The indictments returned at the last term of the Federal Court charged the Lamberts with organizing an automobile company and selling agencies over the country on a basis of $100 deposit each. The Crown company had sold about 400 of those agencies but had not manufactured more than twelve or fifteen cars. Of the 400 agencies so purchased, 100 stopped payment on their checks. Agents were secured for territory in Minnesota, Pennsylvania, Oklahoma, Kansas, Nebraska, Ohio, and other states. For the $100 each agent was given exclusive territory, and also one share of 5 per cent. stock. The deposits were to be returned in credits of $25 each on the first four cars purchased, the indictments charge. Attached to the indictments are letters which show that the dealers were afterwards required to deposit from $50 to $100 as advance freight.

The relationship between the Crown Motor Car Co. and the Hercules Motor Car Co. was as follows: The Crown company was organized in March, 1913, under the laws of South Dakota, with an organized capital of $500,000 and with B. F. Lambert, president; A. B. Lambert, vice-president, and C. H. Lambert, secretary and treasurer. The place of business was 131 North Third street, Louisville. In April, 1914, the Hercules Motor Car Co. was organized under the laws of South Dakota, with an authorized capital stock of $1,500,000, of which $500,000 was to be preferred stock. Its officers were C. H. Lambert, president; B. F. Lambert, vice-president, and A. B. Lambert, secretary and treasurer. The Hercules company took over all the assets and assumed all the liabilities of the Crown company. The plant and machinery of the Crown company were taken over for a reasonable amount.

The Hercules company invited 300 agents of the Crown company to transfer their contracts to the newly formed Hercules company, which over 200 of them did. Twelve or fifteen Crown models were delivered, and most of the remaining agents, those who had neither received cars nor transferred their accounts, received their money back.

It was after April of this year that several of the dealers who had made the original deposits of $100 and subsequent deposits of $100 for freight, began to complain to the postal authorities. A number of them appeared before the Federal Grand Jury here 2 weeks ago, the result being the indictments on eleven counts under Section 215 of the Penal Code. Each count charges that the Lamberts devised a scheme and artifices to defraud some particular man by fraudulently organizing themselves under the name of the Crown Motor Car Co., etc., etc.

I. C. Soper, auditor of the Hercules company, and also a stockholder, states that the company never refused a single demand for the return of the deposit money and that this money is at present being held and will be returned if cars are not delivered. He says the Hercules company has $10,000 or $12,000 which the Crown company received in deposits and that the dealers who put it up could get it back for the asking. To date the company has only turned out about 100 cars, but expects to turn out thirty-five more within the next 10 days.

Business Conditions in Italy Are Tranquil

New York City, Oct. 26—The R. I. V. Co., manufacturer of ball bearings, has received information from its factory in Officine de Villar Perosa, Italy. The information states that there is nothing to fear in that country. As to delay in shipping there is nothing to cause any apprehension as long as Italy is keeping its neutrality. Referring to the talk of the disturbing conditions of that country, no weight should be given it. Business is going on as usual. The R. I. V. Co. is receiving an average of one large shipment a week.

Schrader Opens London Office and Factory

New York City, Oct. 26—A. Schrader's Son, manufacturer of tire valves and tire pressure gauges, will establish a London office and factory. The branch will be at 14-16 Dorset place, London, and will be in charge of W. H. Cole. The machinery and entire equipment has already been shipped and the factory is expected to be in full operation before the end of the month.

Action Expected Shortly on Ferry Charges

New York City, Oct. 26—To secure official action on the claim that automobiles are discriminated against in connection with ferry charges, the Traffic Department of the National Automobile Chamber of Commerce announces that the matter will be taken up again within another week or so, in conjunction with other automobile associations and the Merchants' Assn. of New York.

When this subject was discussed before Dock Commissioner Smith in July, representatives of the manufacturers, dealers and users of trucks showed that discrimination exists on practically all municipal ferries and railroads, in the rates charged on self-propelling vehicles as compared with horse-drawn vehicles. The railroads asked for time in which to give the matter consideration, check over their schedules and submit new tariffs for consideration. It was expected that this could be done within 60 days. Some delays were encountered, but the automobile and trucking interests are now hopeful of having the matter determined within a short time.

Stromberg-Equipped Jeffery Makes 28.7 M. P. G.

Chicago, Ill., Oct. 27—*Special Telegram*—Under the auspices of the Technical Committee of the Chicago Automobile Club, with Chairman F. E. Edwards in charge and assisted by Harry A. Tarantous of *Motor Age*, a Chesterfield Jeffery six, equipped with a Stromberg carbureter, today covered 28.7 miles on 1 gallon of Red Crown gasoline of 57.5 degrees at 47.5 Fahrenheit, the trip being made over the Chicago boulevards. The car and passengers weighed 4,100 pounds, and the ton mileage was 58.8 ton-miles.

It was a cold day, the temperature being 42 degrees. The speed was from 18 to 22 miles per hour and the clutch was not disengaged during the trip except when necessary because of a stop in the traffic. Following the fuel test and without changing the carbureter adjustments, the car was driven from a standing start to 30 miles per hour in 12 4-5 seconds. Still without change in the carbureter adjustment, the car was driven at 4 miles per hour on high gear and was speeded up to 44 miles per hour. Road conditions would not permit of greater speed. The test finished with a climb up Hubbard's hill. Going through the gears, the car attained a speed of 15 miles an hour in high at the top. Crossing the starting line at 11 miles an hour in high gear the Jeffery was going at 18 miles an hour at the top of the hill.

The test was conducted for the Stromberg Devices Company and the carbureter used was a model H B 1. A Stewart speedometer was used.

Federal Truck to Share Profits with Employes

Detroit, Mich., Oct. 26—The Federal Motor Truck Co., Detroit, will install a profit-sharing plan on January 1, 1915. Every employe was informed that all who were at work on December 31, would receive a share of the profits of the concern. This share was to be equal to 10 per cent. of the worker's yearly salary.

Gasoline Drops ½ Cent in Indianapolis

Indianapolis, Ind., Oct. 26—The market price of gasoline has taken another decline at Indianapolis and is now 11 cents. This is a decline of one-half cent a gallon. Dealers who have contracts obtain gasoline at 1-2 cent a gallon off of market price. There has been a total decline in the market price of 3 cents a gallon since January. The retail price remains unchanged at from 13 to 16 cents a gallon.

Market Reports for the Week

The usual changes occurred in this week's markets. Prices were generally steady, but in many cases where the changes occurred, they fluctuated. Antimony this week is in good demand and as a consequence prices are higher by $0.03. This metal gained on an average 1-2 cent per day. Both Bessemer and open-hearth steels dropped $0.50 per ton. Copper is heavier and lower. The capture of three more ships carrying copper from New York City to Europe, apparently for Germany, has had a depressing effect here. The demand on electrolytic copper was light. Tin had a very fluctuating week, its highest price being $31.75 and its lowest price being $1.25 lower. The American October deliveries of tin are expected to be 2,800 to 3,000 tons. Lead is in fair demand and again stronger. The rubber market was very steady. Fine Up-River Para remained constant at $0.66 while tire scrap, which hardly ever changes in price, remained at $0.05. There were no changes in the oils, lubricants and chemical markets. Cottonseed oil, however, dropped $0.35 a barrel.

Records Broken at Galesburg Dirt Track

New Marks Set for 50, 75 and 100 Miles—Mulford Wins Century in 1:32:54.5

GALESBURG, ILL., Oct. 23—New dirt track records for 50, 75 and 100 miles were created yesterday in the century race on the local track, promoted by the Galesburg District Fair Assn. Ralph Mulford in a Duesenberg was the winner, but it was an unexpected victory, made possible by Bob Burman running out of gasoline within 1-4 mile of the finish. Burman in his Peugeot had led the field from the 20-mile post, when DePalma was forced to go into dry dock because of dirt clogging the gasoline line. He had driven carefully and fast and no one questioned his victory. In fact it was something like the 1912 race at Indianapolis when DePalma spreadeagled the field. But in the backstretch of the last lap Burman was seen to slow and at the three-quarter pole he was simply rolling along. Mulford had been trailing all the way and was not more than 1-2 mile behind the pacemaker at any stage. So when Burman faltered he was in an excellent position, shooting by the slowing Peugeot and getting the checkered flag first, 10 seconds ahead of Burman, who had enough momentum to coast home from the three-quarter pole.

Five Cars Allowed to Finish

Five cars were permitted to finish. Tom Alley in a Duesenberg was third; Eddie O'Donnell in another Duesenberg was fourth, and J. D. Callaghan in a Keeton was fifth, while Tidmarsh in the Great Western was still running. Those who had docked at the pits included DePalma in the Mercedes six, Gunning in the Fiat Tornado and Rawlings in a Mercer.

Neither Mulford nor Burman made a stop and there were few cases of tire trouble. If Burman knew he was running out of gasoline he could not stop, for Mulford was barking at his heels all the time. Burman was fooled as to his gasoline, for yesterday he used twice as much as he did in the 100-mile race at Kalamazoo.

At the outset it looked like a keen battle, for DePalma, starting in the second row, took the lead immediately, followed by Burman. The pair raced together for 20 miles, with Mulford trailing. Then DePalma had to slow because of the dirt in the gasoline line and at 27 miles he put up at the pits. Working for 15 minutes, he cleaned out the line, then started again in order that the spectators might have some excitement. He started out to catch Burman and turning miles in :53 and :54 he gave a clever exhibition. The lap in which he caught Burman on the far turn was made in :52, DePalma showing his track cunning by holding the pole in a most sensational manner in his swing into the homestretch. A stop for a tire change followed, then DePalma resumed the race but quit a few miles later, when his fuel line again clogged.

One accident marred the race. In his thirty-first lap Jack Gable in the Burman Special turned partly over going into the last turn, caused by a rear wheel collapsing in the backstretch. Gable escaped with a few bruises, but Fritz Walker, his mechanic, was more severely hurt. Walker was taken to the Galesburg hospital.

The track was in perfect condition. Recent rains helped and so did calcium chloride. The course was almost dustless and stood up under the long grind, being really better at the finish than at the start. The weather, too, was ideal, there being no wind. Because of these conditions, it was no wonder records were broken. The 50-mile mark of 46:32, held by Disbrow, was cut to 45:48 by Burman. The 75-mile record of 1:11:21, held by Burman, was dropped to 1:08:54 3-4 by Burman, while Mulford gets the century mark, his 1:32:54 1-2 beating the 1:34:29 4-5, made by Burman at Kalamazoo. This mark is not yet official, however. The time of the race for each 5 miles was as follows:

DISTANCE	TIME	LEADER	DISTANCE	TIME	LEADER
5	4:26½	DePalma	55	50:23½	Burman
10	9:02	DePalma	60	55:01	Burman
15	13:40	DePalma	65	59:40⅕	Burman
20	18:14	DePalma	70	1:04:15½	Burman
25	22:43½	Burman	75	1:08:54¾	Burman
30	27:17	Burman	80	1:13:41	Burman
35	31:51	Burman	85	1:18:30⅕	Burman
40	36:31⅕	Burman	90	1:23:17	Burman
45	41:09	Burman	95	1:27:57	Burman
50	45:48	Burman	100	1:32:54½	Mulford

The summary of the race was as follows:

CAR	DRIVER	TIME
Duesenberg	Mulford	1:32:54½
Peugeot	Burman	1:33:08½
Duesenberg	Alley	1:33:37
Duesenberg	O'Donnell	1:37:33
Keeton	Callaghan	1:37:41
Great Western	Tidmarsh	Still running
Mercedes	DePalma	Out
Burman Special	Cable	Out
Fiat Tornado	Gunning	Out
Mercer	Rawlings	Out

The success of the race was such that the Galesburg association is planning something bigger for next year. It is proposed to widen the track, hang up at least a $5,000 purse and stage a 200-mile race about June 15, in between Indianapolis and Sioux City. It is suggested that this be an invitation affair, limited to ten or a dozen cars.

DETROIT, MICH., Oct. 24—Since April 1, 1914, the Saxon Motor Co., has shipped 6,200 cars of which many went to foreign lands. June was the Saxon's biggest month, 1,787 cars being shipped, while the biggest day was June 22, when 103 cars were shipped.

Duesenberg Breaks Century Mark on Hamline Track

MINNEAPOLIS, MINN., Oct. 24—Tom Alley in a Duesenberg car today established a new dirt track record for 100 miles at Hamline, under adverse conditions. His time was 1:31:30 as against the official time of 1:40:15 made by De Palma in a Mercedes at Brighton Beach on September 2, 1914. He averaged a little over 65 miles an hour. The others who finished were as follows: Mulford, O'Donnell and De Palma.

The race was a Class D, non-stock, free-for-all, flying start and the prizes were as follows, first, $1,000; second, $750; third, $500; fourth, $250; and for breaking the world's record, $1,000.

The race was on a 1-mile dirt track, which was over heavy due to excess of calcium chloride with the addition of rain.

Big Automobile Representation in Tercentenary

NEW YORK CITY, Oct. 28—Over 1,200 motor vehicles, including passenger cars and commercial trucks, were represented in tonight's celebration of New York's 300th business birthday. The Commercial Tercentenary Celebration, commemorating 300 years of chartered commerce in this country, started on Sunday, October 25, when President Wilson opened the religious feature of the celebration in this city. The motor vehicle pageant, which was held tonight, was composed of floats, automobiles and motorcycles, exclusively. The entrants competed for $5,000 worth of prizes, which were offered by the State and $1,000 additional from other sources.

A reception was given to Governor Glynn and Mayor Mitchell at the Automobile Club of America, both of whom rode at the head of the pageant and reviewed it from the Court of Honor at Forty-second street and Fifth avenue.

Two Stutz Cars Entered for Corona

CORONA, CAL., Oct. 21—Charles Klein, driver of the King car at Indianapolis and in the motor race meets of the Northwest this summer, has contracted to pilot the second Stutz entered by Walter M. Brown in the Corona road race which is scheduled to take place on the Circle City course, Thanksgiving Day. The third Stutz driver is to be Barney Oldfield, if he gets through the strenuous Los Angeles-to-Phoenix road race safely and with his car in condition to start at Corona.

Eighteen in Los Angeles-Phoenix Road Race

LOS ANGELES, CAL., Oct. 23—Entries for the seventh annual Los Angeles-Phoenix automobile road race closed yesterday with eighteen cars nominated. The start will be made here on the morning of November 9, with night controls at Needles, Cal., and Prescott, Ariz., and the finish will be at Phoenix, Ariz., on November 11. Two mountain ranges and the Mojave desert must be crossed. The course will be about 700 miles and state highways will be patrolled by the militia. A diamond medal has been offered for the winner.

The list of cars and drivers follows: Paige, Louis Nikrent; Chevrolet, L. R. Lawrence; Unknown, unknown; Simplex, O. Davis; Stutz, Barney Oldfield; KisselKar, D. Anderson; Maxwell, W. Carlson, Jr.; Paige, T. J. Baudet; Metz, unknown; Kincaid Special, J. Greenwood; Metz, unknown; Buick, H. Ellis; De Dietrich, unknown; Stutz, J. Burns; Thomas, H. J. Pink; Cadillac, W. W. Bramlette.

100 Models on Display at Los Angeles

LOS ANGELES, CAL., Oct. 17—The annual Los Angeles automobile show opened at the Shrine auditorium this afternoon with more than 100 new models on display, representing twenty-six agencies. The Los Angeles show is the first of the Western season. There were so many machines on the floor that exhibits were staged in the lobby and in private rooms off from the main show room. Accessory exhibits, representing every branch of the industry, have been placed in the balcony.

The second week of the show is to be given over to the motor truck industry. The automobiles are to be taken off the floor by midnight, Friday, October 23, and the following afternoon the truck show will open.

The attendance on opening day broke all records for automobile shows in Southern California.

Fifty 1915 Models at Madison's Fall Show

MADISON, WIS., Oct. 26—Fifty 1915 models were displayed by Madison, Wis., dealers at the first annual fall automobile show, conducted in connection with Madison's big Fall festival last week. The display occupied a huge tent, there being no building available to house the collection of cars. Among the cars on exhibition were: Buick, Chalmers, Ford, Saxon, Cadillac, Chevrolet, Hudson, White, Studebaker, Premier, KisselKar, Reo, Moline-Knight, Regal, Oakland and Mitchell. As Madison dealers are for the most part large district agents in western Wisconsin, the show attracted sub-dealers as well as retail buyers from a large territory and a splendid business was done. The show will be repeated next fall and will supplant the annual spring show.

Montreal Show To Be Held Jan. 23-30

MONTREAL, Oct. 22—It has been decided by the Show Committee of the Montreal Automobile Trade Assn. to hold a show from January 23 to 30 inclusive and the same will be held in the Allen Line Liverpool Buildings. This year's show will, as above, be spread over one week only with a special commercial section reserved for trucks, etc. The space at the disposal of exhibitors is 60,000 square feet. Last year's show covered 2 weeks, one for pleasure cars and the other devoted to commercial vehicles.

Detroit Garagemen Form Welfare Association

DETROIT, MICH., Oct. 24—Garage Owners of Detroit have organized the Detroit Garage and Station Operators Assn., the object of which is to promote the welfare of all connected and interested in the garage business. F. A. Bean, of the Grosse Point Garage, was elected president; J. J. Towers, of the Canfield Garage, vice-president; A. J. Dorsey, of the Indian Village Garage, secretary and Roy L. Francis, of the Central Oil Co., treasurer.

There are several important measures which the association is now working up, such as a state garage lien law, revision of the insurance rates which now make no differences between a fireproof garage and a woodshed used as garage in an alley; improve the matter of selling gasoline which now leaves only 1 cent profit per gallon; establishment of an employment bureau and a workable credit system. A state convention will be held in Detroit during the local automobile show.

Illinois Garagemen Condemn "Leagues"

PEORIA, ILL., Oct. 24—The ease with which differences between the retail and manufacturing ends of the automobile trade may be adjusted, provided one or both sides are organized, was demonstrated today at the fall convention of the Garage Owners' Assn. of Illinois. The garagemen are well organized, and the Danville members had complained that a salaried salesman of a manufacturer was conducting a cut-price "curbstone" business in that town to the detriment of the dealer-garagemen. The matter was referred to the state association by the Danville garagemen with the result that, after correspondence, the manufacturer recalled the salesman and appointed dealers in the territory. The Danville garagemen-dealers also suggested that any further matter of price-cutting might be adjusted by consultation with the manufacturer.

The seventy-five delegates convened at 2:30 o'clock yesterday afternoon and the convention ended tonight with a banquet and ball in the Jefferson Hotel. About seventy-five delegates and as many more non-delegates were present. A theater party, luncheon, the banquet and ball and a tour of the town were mingled with the business sessions.

Motorists' "leagues," which generally are formed for the purpose of supplying car owners with supplies and accessories at cut rates, were placed under the ban. The garagemen consider that the sale of supplies is a business which belongs to the garageman, and the body went on record against the "leagues" by a resolution.

In their work to benefit themselves by rendering greater service to their clientèle the garagemen considered a plan whereby a certain Chicago manufacturer will sell them supplies at about half their present price. The alliance between the garage and the factory involves an investment by the association members and the restriction of trade to members.

The Illinois association, which has been laboring for a national organization, made its call official by passing a resolution; organization work is now going on in the East and the national meeting will be held in January in Chicago during the automobile show.

Truck Club Discusses War Trucks

NEW YORK CITY, Oct. 27—"The Use of Motor Vehicles in the European War" was the subject of the evening at the regular monthly meeting of the New York section of the Motor Truck Club of America, held on October 21, at the Automobile Club of America. The speaker was John R. Eustis, of *The Evening Mail*, who also showed thirty-six lantern slides depicting the different types of motor vehicles used and the various ways in which they were adapted to the special requirements of military service.

Commenting further on the use of motor vehicles in war, he stated that the English were the first to make use of this means of transportation, having used steam traction trucks in the South African campaign.

The next meeting of the club will be held on November 18 at the Automobile Club of America.

PHILADELPHIA, PA., Oct. 24—C. C. Partin, manager of the division of motor truck research of the Curtis Publishing Co., was the principal speaker of the monthly dinner and business meeting of the Motor Truck Assn., this city, held this week. His address dwelt on the necessity of advertising. In regard to establishing the reputation of a truck, he stated that oftentimes a truck of unknown rating is regarded with suspicion, and should one of this class be installed, there is a constant protest against repair expenditures, it being believed that these could have been avoided with the right kind of machine, whereas a truck of nation-wide repute carries with it the equally well-known fact that such outlays are unavoidable.

Mitchell Finishes 7,500-Mile Sealed-Bonnet Run

PITTSBURGH, PA., Oct. 23—The Mitchell car which started from Chicago, Ill., on September 23, with its bonnet sealed, arrived in this city today, after traveling 7,518.4 miles, its seals still intact. The car touched twenty-three states and Washington, D. C., en route.

Grossman Buys Windshield Cleaner Patent

NEW YORK CITY, Oct. 28—The Emil Grossman Mfg. Co., Inc., Brooklyn, has purchased patent No. 1,112,793 for the Security Windshield cleaner, issued to C. J. Heineman, May 11, 1914, as well as his entire right and interest in the invention.

Lincoln Highway Route Three-Quarters Marked

NEW YORK CITY, Oct. 26—Reports received at the headquarters of the Lincoln Highway Assn., indicate that at least 2,700 miles of the route will be marked by the end of the first year's work on October 31. Indications are that by the spring of 1915 the entire distance of 3,400 miles will be completely marked with at least five markers to the mile.

CHICAGO, ILL., Oct. 28—Mercedes Fritz Walker, mechanic for Jack Gable in the 100-mile race at the Galesburg track last week, died this morning in the Galesburg hospital as a result of injuries received when Gable's car partly overturned in the 31st lap.

DODGE Additions Worth $650,000—Dodge Bros., Detroit, Mich., manufacturers of the "unknown" car, are still expanding their already large plant. A new pressed-steel shop and the doubling of their general offices have been let to the contractors and will mean a total outlay of $650,000. The pressed-steel plant will a four-story building, 400 feet long and 77 feet wide, which will have a total floor area of 130,000 square feet. It will be connected with the new assembling plant through an extension of the latter building by 189 feet. A wing will also be built 89 feet long and 77 feet wide, to connect it with the loading platform, railroad tracks and driveways. The first two stories will be of steel frame and concrete throughout, while the two other stories will be of reinforced concrete. The exterior will be similar in construction and design and color to the other Dodge buildings. The general office and administration building, which now is a two-story structure, 116 feet by 52 feet, will be enlarged to be a four-story building, 320 feet long and 72 feet wide.

New Plant for Detroit—American Auto Trimmings Co., Detroit, Mich., will build a four-story brick and steel manufacturing plant, estimated cost $36,500.

Alpha Seeking Plant Location—The Alpha Mfg. Co., Bucyrus, O., manufacturer of a line of pumps, is seeking a location to establish a plant in that city.

Endurance Tire's New Brunswick Plant—The Endurance Tire & Rubber Co., New York City, will build a factory 80 by 250 feet, one story, of brick construction, at New Brunswick, N. J., to cost $50,000.

Automobile Factory in Spencer—The Spencer Mfg. Co., Spencer, O., has been incorporated with $50,000 capital stock. It is reported that it will erect a plant for manufacturing automobiles.

Homer Co. to Build Trucks—The directors of the Homer Motor Co., Los Angeles, Cal., have set aside $65,000 for the erection of a factory that will have a capacity of twenty-four motor trucks a month.

Top Co. to Build—The Topford Detachable Limousine Co., Hempstead, L. I., N. Y., will establish a plant for the manufacture of detachable automobile bodies and limousine tops, doors, etc., and general automobile accessories. The estimated cost is $50,000. J. A. MacAvoy and W. Hutchinson, Hempstead, L. I., are interested.

Ford's New L. I. Plant—Ground has been broken for a new eight-story building of concrete, steel and brick construction for the Ford Motor Co., at Honeywell street and Jackson avenue, Long Island City, east of and adjoining its present building. The new building will have a frontage on Jackson avenue of 325 feet and will cost about $650,000.

Triple Action Spring Adding—The Triple Action Spring Co., Chicago, Ill., manufacturer of the Johnson shock absorbers, is making big additions to its factory, located in East Twenty-eighth street, near Michigan avenue. The new plant when completed will occupy 29,000 square feet of floor space, which will enable the company to double the output.

Canadian Battery Co. Adds—The Canadian Hart Accumulator Co., St. John, N. B., is erecting a large factory there for the manufacture of storage batteries. The company will manufacture a complete line of sulphuric acid batteries and all types of plates on the same principles as the batteries made in Great Britain. C. W. Knighton is the Canadian manager.

Spring City Foundry Adding—The Spring City Foundry Co., Waukesha, Wis., established about 2 years ago, and now supplying several important motor and automobile interests in the Middle West with cylinder and engine castings, is making plans for the erection of an addition which will double its foundry capacity. The addition will be 60 by 122 feet in size and will be equipped principally for making grey iron castings for automobile cylinders and other cast-iron parts.

Blood Bros. May Move—The Blood Bros. Machine Co. may remove from Kalamazoo to Allegan, Mich. It is not yet decided, but at a meeting between members of the local Board of Trade and other citizens and Vice-President Howard E. Blood, of the Blood concern, it became known that if a site and a building is furnished and if a certain amount of stock of the company taken by local people, that the chances are Allegan will have the automobile concern. The Blood company would keep the Kalamazoo plant for the manufacturing of its universal joints and other parts, while the Cornelian light car would be made in Allegan.

Nyberg May Build in Fort Smith—E. R. Call, of the Nyberg Automobile Mfg. Co., Anderson, Ind., recently stated to the Business Men's Club of Fort Smith, Ark., that his company had expressed a willingness to locate in that city. He also stated that a company had been organized for the taking over of the Nyberg Automobile Mfg. Co. and that company in reorganizing had looked over the situation and decided upon a Southwestern location, Fort Smith being one of the towns picked out. In mentioning the reasons for this location he stated that four-fifths of the cars sold by the company were south of St. Louis and Kansas City. If the company decides to build in Fort Smith, a factory with a floor space of 40,000 square feet, a capacity for 200 skilled mechanics and an output of 1,200 cars a year, will be erected.

The Automobile Calendar

Oct. 17-Nov. 1	Dallas, Tex., Show, State Fair Grounds, Dallas Automobile Dealers' Assn.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov. 2-6	Boston, Mass., Salon, Copley Plaza Hotel.
Nov. 3	Long Island A. C. Century Run.
Nov. 7-8-9	Los Angeles, Cal., Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 8	Philadelphia, Pa., Fletcher Cup Run, Automobile Club of Philadelphia.
Nov. 8-9	El Paso, Tex., El Paso-Phoenix Road Race, El Paso Auto Club.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 12	Phoenix, Ariz., Track Race, Maricopa Auto Club.
Nov. 17-18-19	Harrisburg, Pa., Second Conference of Pa. Industrial Welfare and Efficiency, State Capitol.
Nov. 26	Corona, Cal., Road Race, Corona Auto Assn.
Dec. 1-4	New York City, Annual Meeting of the American Society of Mechanical Engineers.
Dec. 12-19	Akron, O., Show, Akron Auto Show Co., O'Neill Bldg.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace.
Jan. 3-10	Buenos-Aires, Argentina, Grand Prize of Argentina.
Jan. 9-16	Philadelphia Show.
Jan. 11-16	Buffalo, N. Y., Show, Broadway Auditorium, Automobile Club of America.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.
Jan. 23-30	Montreal, Que., Show, Allen Line Liverpool Bldgs., Montreal Automobile Trade Assn., T. C. Kirby, Mgr.
Jan. 30-Feb. 6	Minneapolis, Minn., Show, National Guard Armory, Minneapolis Automobile Trade Assn.
Feb	Portland, Ore., Show, Portland Auto. Trade Assn.
Feb. 15-20	Omaha, Neb., Show, Auditorium, C. G. Powell.
Feb. 22	San Francisco, Cal., Vanderbilt Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.
Feb. 23-27	Syracuse, N. Y., Show, Syracuse Auto. Dealers' Assn.; H. T. Gardner, Mgr.
Mar. 6-13	Boston, Mass., Show, Mechanics Bldg., Boston Auto Dealers Assn., Boston Commercial Motor Veh. Assn.
Mar. 7	San Francisco, Cal., Panama-Pacific Exposition, Grand Prize Race, Panama-Pacific Exposition Grounds: Promoter, Panama-Pacific Exposition Co.
Mar. 9-15	Des Moines, Ia., Show, C. G. Van Vliet.
Mar. 14	San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

The Week in  the Industry

Motor Men in New Roles

McGUIRE Oldsmobile Advertising Manager—C. V. McGuire, until recently in charge of the publicity department of the Lozier Motor Co., Detroit, and previous to that connected with the advertising departments of the Paige-Detroit Motor Car Co. and the United States Tire Co., has been appointed advertising manager of the Olds Motor Works, Lansing, Mich.

Scott Resigns—Emmet Scott has resigned the treasurership of the M. Rumely Co., Laporte, Ind., effective October 31, so he can devote more time to his own affairs.

Quimby Resigns—E. F. Quimby has resigned from the position of secretary and general manager of the Colfax Mfg. Co., South Bend, Ind., and has been succeeded by S. P. Colby.

Coler Resigns from Overland—Ernest Coler has resigned as advertising manager of the Willys-Overland Co., Toledo, O., to take a similar position with the Briscoe Motors Co., Jackson, Mich.

Estep Joins Cheltenham Press—E. Ralph Estep, former advertising manager of the Packard Motor Car Co., Detroit, Mich., has joined the Cheltenham Press, an advertising agency in New York City, in which he now has a stockholding interest.

Hole Promoted—F. H. Hole, manager of the St. Louis branch of the H. E. Wilcox Motor Co., has been promoted to an executive position with the company at Minneapolis. He was succeeded by J. E. Westrich, who has been the company's service agent.

Milwaukee's Former Mayor Manager—S. M. Becker, formerly mayor of Milwaukee, Wis., has taken the position of manager of the electric vehicle department of the Jesse A. Smith Automobile Co., that city, and will handle Milwaukee and the vicinity in behalf of the Detroit electric.

Rand Simplex Branch Manager—C. D. Rand, who was assistant manager under Bert Latham, has just been appointed branch manager of the Simplex Mercer Pacific Coast agency in San Francisco. Mr. Rand has been connected with the agency ever since its establishment in San Francisco.

Horning to Open Consultation Bureau—W. R. Horning. 1408 West Third street, Cleveland, O., will in the near future establish a service station and consultation bureau on all makes of automobile starting and lighting systems. This station will be opened about November 15 at 1020-1030 Chestnut street, that city.

Pelletier and Tripp Form Advertising Co.—The advertising firm of Pelletier-Tripp, Inc., has been formed in Detroit, Mich., by E. LeRoy Pelletier and William Tripp. Headquarters have been secured in the Fine Arts Bldg. The accounts of several of the big automobile manufacturers have been secured by the corporation. Both men are well known in the automobile, parts and accessory industry of the country. Roy Pelletier has successfully handled the advertising of the Ford, Maxwell, Flanders and Lozier companies. William Tripp has been for many years with the advertising department of the Class Journal Co.

Chapin to Be a Benedict—Cards have just been issued for the wedding of R. D. Chapin, president of the Hudson Motor Car Co., Detroit, Mich., to Miss Inez Tiedeman at St. John's Church, Savannah, on November 4. The bride-to-be is the daughter of Mayor Tiedeman, who was a member of the Savannah Automobile Club's race committee during the Grand Prize and Vanderbilt Cup races.

Wallis Resigns from J. I. C.—H. M. Wallis, Jr., secretary and treasurer of the J. I. Case Plow Works, Racine, Wis., for a number of years, has resigned these positions and retired as a director to be able to devote his entire time and attention to the development of the Wallis Tractor Co., which he organized about 18 months ago, and which now is manufacturing Wallis tractors at Cleveland, O. Mr. Wallis' father, H. M. Wallis, Sr., continues as president of the plow company, which at various times has been interested in the motor car industry, principally as state and territorial agent and distributor for pleasure cars.

Recent Changes on Pacific Coast—D. A. Outcault, a member of the Tacoma Speedway Assn., has been elected president of the Tacoma Automobile Club, and E. B. King succeeds Mr. Outcault as vice-president. The organization of the De Vaux Motor Sales Co., a Los Angeles corporation, has been completed with E. J. Bennett as sales manager. The Grant car now has a new home in Seattle with the Grant Motor Agency, which is established in new quarters at 1026 East Pike street. F. W. Blair is manager of the agency, and associated with him is F. W. Venable. A. C. Stevens, for 2½ years with the Winton Motor Car Co. in Seattle, has been appointed manager of the Winton branch in Portland, Ore., succeeding Bert Roberts, and T. A. Crisman, formerly of the Blaine Auto Co., of Iowa, has joined the sales force of the Hodgins-Fosdick Co. in Spokane, Wash.

Garage and Dealers' Field

Jandorf's New Lease—The Jandorf Automobile Co., New York City, has leased the second and third floors in 351-355 West Fifty-second street, that city.

Ford's New Bronx Lease—The Ford Motor Co., Detroit, Mich., has leased the six-story building at 607-609 Bergen avenue, Bronx, New York City. This building is 50 by 100 feet in size.

Saxon Now a Branch—The Saxon Motor Co. has been formed in Boston, Mass., to handle the Saxon cars in that territory as a factory branch, instead of an agency and salesrooms have been secured at 620 Commonwealth avenue, with F. S. Sumner as manager.

Houpt's New Repair Station—Harry S. Houpt, Inc., agent for the Mitchell car, has leased property at the northwest corner of Forty-seventh street and Eleventh avenue, New York City, or 645 to 651 Eleventh avenue, to be used as a storehouse and repair station.

G. M. C. Makes a Move—The Boston branch of the General Motors Truck Co. is now housed in one building, the salesrooms on Boylston street having been discontinued, the offices being moved to the service station at 944 Massachusetts avenue, where everything is under one roof.

Ford to Have Retail Branch—The Ford Motor Co. has leased quarters on Boylston street, Boston, Mass., formerly used by the Alco forces, where it will establish a retail branch to be run in connection with its wholesale distributing plant in Cambridge, Mass.

Assn. Plans Own Garage—The Automobile Owners' Assn., Grand Rapids, Mich., is planning to have a garage, service station, supply and accessories department and vulcanizing station of its own. It is estimated there would be a saving of at least 50 per cent. on automobile supplies alone.

Dayton Wants Fire Apparatus—The announcement is made by City Manager Waite of Dayton, O., that bids for a number of pieces of motor-driven fire apparatus will be advertised for in the near future. The city proposes to purchase a chemical arial truck, a tractor, a service truck and a runabout.

Akron Agencies Under One Roof—Plans have been prepared for the erection of a $75,000 building at the corner of Water and Bowers streets, Akron, O., which will be devoted exclusively to sales agencies for automobiles. It is planned to house many of the agencies of the city in the building. The basement will be used as a workshop and the upper floors for showrooms.

Lincoln Highway Emblem on Motometer—The MotoMeter Co., New York City, maker of the Boyce motometer, was licensed by the Lincoln Highway Assn. to the exclusive right to use the Lincoln highway emblem on radiator heat indicators. No additional charge will be made for motometers supplied with this emblem, but it is understood that for each Lincoln highway motometer sold that company has agreed to contribute a certain amount to the Lincoln highway cause.

Bosch Adds New Stations—The Bosch Magneto Co., New York City, has recently added the following supply stations: Olympia Auto Supply Co., Olympia, Wash.; Max Gottberg Auto Co., Columbus, Neb.; James Auto Co., Ogden, Utah; I. P. Todd, Circleville, O.; G. O. Reynolds, Inc., New Rochelle, N. Y.; Marksheffel Motor Co., Colorado Springs, Col.; Eleventh Avenue Garage, Altoona, Pa.; Graham-Seltzer Co., Peoria, Ill.; North West Garage, Cherokee, Iowa; Union Garage, Lansing, Mich.; Plank & Morgan, Worcester, Mass.; Crater Lake Motor Car Co., Medford, Ore.; T. A. Bryson, Savannah, Ga.; Pendleton Auto Co., Pendleton, Ore.; Clyde Garage, Charleston, S. C.; Milton Garage, Milton, Ore.; Motor Car Supply House, Decatur, Ill., and Triple Star Garage, Kahoka, Mo

Recent Incorporations in the Automobile Field

Arkansas

ARGENTA—W. F. Brawley Motor Co.; capital, $10,000. Incorporators: W. F. Brawley, John D. Staples and W. R. Deen.

Canada

TORONTO, ONT.—Canadian Simplex Motors; capital, $40,000.

Indiana

INDIANAPOLIS—Higgins-Craig Co.; capital, $20,000; to deal in motor cars. Incorporators: George W. Higgins, J. R. Craig and William R. Higgins.

INDIANAPOLIS—Perfection Spring Wheel Co.; capital, $50,000; to manufacture wheels. Incorporators: Harry Weill, Max Weill and George V. Stein, all of Indianapolis; Austin Cabel and Bret Cabel, both of Washington, Ind.

New York

BROOKLYN—Schroeder-Peters Corp'n.; capital, $20,000; to manufacture engines, motor vehicles, operate a machine shop, etc. Incorporators: Arthur A. Schroeder, 346 Avenue O; Cuyler Heath, 172 Halsey street; Frank R. Greene, 27 Grace court.

HIGHLAND—Howard W. Bloomer, Incorporated; capital, $10,000; motor car business. Incorporators: Howard Bloomer, Highland; Raymond C. Bloomer, 96 Washington street, Poughkeepsie; Charles H. Buys, Jr., Cannon street, Poughkeepsie.

NEW YORK—Economy Parts Co.; capital, $1,000; to manufacture parts for motor cars, motorcycles, etc. Incorporators: George K. Erb, Asbury Park, N. J.; Alan D. Morrow, 220 Broadway; J. Wallace Mahlstadt, 2766 Boulevard, Jersey City, N. J.

NEW YORK—Sole Distributing Co.; capital, $15,000; to conduct a motor car business. Incorporators: Nancy Stamm, 1476 Seabury place, Bronx; Lida S. Davies, 590 W. 172d street; Herman P. Lowenstern, 501 East 140th street.

YONKERS—R. U. Bunker Engineering Co.; capital, $20,000; motor car engineering and designing, motor car parts, etc. Incorporators: Raymond U. Bunker, No. Broadway; David H. Well, Flushing; George O. Elmore, Brick Church, East Orange, N. J.

North Dakota

HEBRON—Hebron Motor Co.; capital, $10,000. Incorporators: Theodore J. Bolke, Charles W. Lorenz and Fred Braun, Jr., all of Hebron.

Ohio

CLEVELAND—Neighbors Motor Co.; capital, $10,000; to deal in motor cars. Incorporators: W. C. Barger, M. T. Flanagan, R. Hall, Robert Jamison and Richard Inglis.

LIMA—Buckeye Machinery Co.; capital, $50,000; to manufacture gas engines and other machinery. Incorporators: Edward E. Weiswander, Calvin Weiswander, Jacob A. Weiswander, George A. Hevrett and Daniel Armentrout.

Oklahoma

BROKEN ARROW—F. O. B. Automobile Co.; capital, $1,000; to deal in motor cars. Incorporators: R. R. Hord, H. C. Hunsecker and L. F. Copeland, all of Broken Arrow.

Tennessee

MEMPHIS—Atlas Machine & Garage Co.; capital, $2,000; to manufacture and sell motor car parts and accessories and operate a garage. Incorporators: H. E. Bridges, J. C. Scott, J. C. Bailey, W. D. Keysey and A. C. Fant.

Virginia

ROANOKE—Overland Roanoke Co.; capital, $4,500; to deal in motor cars. Incorporators: Gordon Lefebre and F. S. Cooper, both of Roanoke, and others.

Washington

BELLINGHAM—Whatcom Auto Co.; capital, $5,000; to deal in motor cars. Incorporators: Perry B. Newkirk, Frank W. Radley and Thomas R. Waters, all of Bellingham.

EVERETT—Mackey Bros.; capital, $2,500; to deal in motor cars. Incorporators: James Mackey, George Mackey and others.

KENNEWICK—Kennewick Auto Co.; capital, $3,000; to deal in motor cars. Incorporators: John A. Penn, William L. Muncey, D. M. Williams, J. E. McKinney and L. H. Marks.

GARAGES AND ACCESSORIES

Alabama

BIRMINGHAM—Universal Service System; capital, $10,000; to conduct a general motor vehicle business. Incorporators: F. J. Bradley, W. C. Nabb and others.

Canada

QUEBEC CITY, ONT.—Safety Tire Co.; capital, $1,000,000.

MONTREAL, QUE.—Higgins & Lee Motor Supplies; capital, $50,000; manufacturers' agents and dealers in motor car supplies. Incorporators: R. S. Higgins and others.

Delaware

WILMINGTON—Storage Battery Locomobile Co.; capital, $50,000; to manufacture and sell storage batteries and electrical machinery. Incorporators: C. B. Bishop, C. J. Jacobs and H. W. Davis, all of Wilmington.

Illinois

CHICAGO—Century Auto Tire & Supply Co.; capital, $10,000; to manufacture and deal in motor car accessories. Incorporators: B. M. Goff, C. A. Wever and B. M. Goff.

CHICAGO—Chicago Auto Equipment Co.; capital, $2,500. Incorporators: Harold M. Behan, Emil Fantana and William H. Dellenback.

Louisiana

SHREVEPORT—Shreveport Overland Co.; capital, $50,000; to conduct a general motor vehicle business.

Michigan

DETROIT—Detroit Enclosed Body Co.; capital, $10,000. Incorporators: Carl A. Zeller, Jr.; Gerald Wright and Grover Farnsworth.

DETROIT—National Motor Appliance Co., capital, $25,000. Incorporators: Sidney B. Winn, Nathan H. Jewett and Howard Streeter.

DETROIT—R. T. W. Auto Accessory Co.; capital, $5,000. James H. Pratt, William H. Lankin and Edward W. Mills.

New York

BROOKLYN—Whipple Garage; capital, $3,000. Incorporators: Edward Appel, 443 East 138th street, New York; John C. Wolff, 27 North Washington street, Jamaica; James E. McKenna, 29 Boerum place.

NEW YORK—Æon Garage Corporation; capital, $500. Incorporators: Sumner Gerard and Nathan A. Smyth, both of 50 Broadway; Lorne A. Scott, 243 West 55th street.

NEW YORK—The 474 West 130th Street Garage; capital, $1,000; to operate a garage. Incorporators: George A. Adams, 149 Church street; Bernard Linn, 456 Washington street; Charles Goldman, 41 Park Row.

NEW YORK—Motor Devices Co.; capital, $30,000; motor car accessories. Incorporators: William A. Allen, Yonkers; Auckland B. Cordner, 1733 Broadway; David Wills, 954 Boulevard, Astoria, L. I.

NEW YORK—Washington Heights Auto Tire Works; capital, $5,000. Incorporators: William J. Buckley and Edward Buckley, both of 1748 Amsterdam avenue; William F. Keyes, 526 West 145th street

Accessories for the Automobilist

Detroit Ball Bearing Universal—A universal of the ball bearing type is shown in Fig. 1. The body of the universal, which is keyed to the gearset, or the bevel pinion shaft, as the case may be, is fitted with four cylindrical grooves. The other member of the universal works in two of these grooves. Friction is largely eliminated because the sliding member is equipped with balls which are attached to a cross-arm.

Several advantages are claimed for this device. In the first place the joint has a smooth exterior; second, it may be easily taken apart by simply unbolting the flange which is keyed to the shaft at one end; third, it will retain its lubrication indefinitely, as there is only one opening to the joint and this is closed by a simple leather sleeve. The joint not only allows a full universal action but also sufficient longitudinal movement so that it acts as a slip joint. It is further claimed that it is cheap to manufacture, almost frictionless and extremely strong. It is made by the Universal Metal Products Co., 518 Woodbridge street, Detroit, Mich.

Electric Safety Signal—To prevent the theft of the car, William Bogler, Hastings, N. Y., has invented an automatic switch which sounds a bell, operates the electric horn or both whenever the starting switch is turned on. This will scare away anyone trying to steal the car. In addition it locks the ignition or electric starting circuit. It is shown in Fig. 2.

The whole apparatus is enclosed in an iron box 2½ by 6 inches, which is made fast to back of dash board under the hood and all that will show is the lock face about 1 inch in front of dash board.

Enclosed in the iron box there is a Yale two-way lock with copper switch blades fastened to the lock bolt, insulated with fiber and connecting with switch points to circuit.

With the key turned to the right, the circuit is closed for running. When one stops his car he throws his switch to off position, turns the kev to the left, removes it from the lock and places it in his pocket, the car is then locked and cannot be run without the key. The lock is pick proof and there are no two keys the same.

Should anyone try to steal the car the first thing he would do would be to throw switch to starting position, since the circuit is open through the right side of lock switch, the car could not be run; but the minute the switch was closed it would make a circuit through the left side of lock switch, connecting with a bell which is also enclosed in the same box, which would sound an alarm.

The bell circuit can also be connected in series with electric horn if desired, which would make a double alarm. This switch can be used with any of the starting systems now in use.

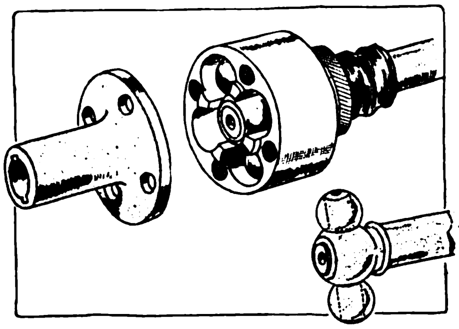

Fig. 1—Detroit ball-bearing universal

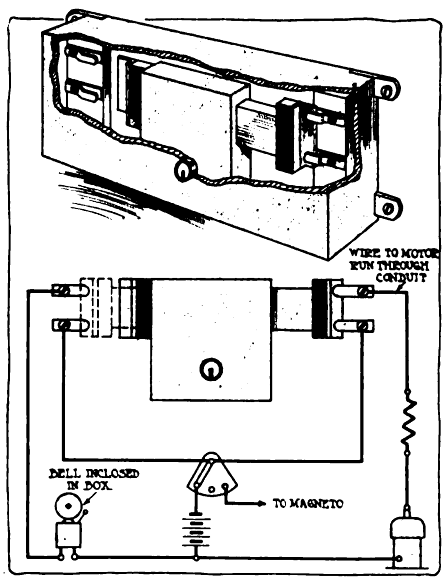

Fig. 2—Electric Safety Signal. Upper view shows the switch and the lower one the connections

Hoggson Joyometer—A device, Fig. 3. for recording the use of motor vehicles, has been patented by S. H. Hoggson, 108 Fulton street, Brooklyn, N. Y. It consists of an eight-day clock movement, which is connected to a printing device which records the divisions of time on a strip of paper tape. Connected with the device is a delicately balanced horizontal pendulum which operates a steel perforating needle that perforates small holes in the paper tape corresponding to the undulations of the car when in motion. When the car is started the recorder begins a series of perforations on the tape, which continues as long as the car runs, and ceases upon the stopping of the car, the perforations being made on the tape at the proper time as indicated by the hands on the clock. The record can be removed at any time or left as long as desired. The inking is done by a special fountain pen roller to which a few drops of ink are added once or twice a year. The recorder uses plain ticker tape and a roll 1.5 inches in diameter is sufficient for a 4 months' record.

The device measures 3.75 by 8.5 inches and weighs about 4 pounds. It may be fastened to any convenient part of the car and, as it is self-contained, it is ready to operate the moment it is attached.

Climax Grease Cup—A grease cup which is designed to operate perfectly under all conditions is shown in Fig. 4. In the first place, it is a simple matter to fill it with grease, merely removing the top cover by turning it to the left a small amount. It will be noted that the cover is held in place by a bayonet locking device which is provided with a split washer to hold it securely in place. Grease cannot pass the plunger, it is stated, because it is made a close fit and is fitted with a cupped leather washer. Ball grips are used to keep the plunger from turning. The cup is made in five sizes and is threaded for ⅛ and ¼-inch standard pipe thread. It is finished in nickel and brass. The prices vary from 25 cents up, the ½-inch brass cup selling for this figure while the nickel-plated one of the same size lists at 30 cents. The 1-inch size costs 45 cents in brass and 50 cents in nickel.

Opco Carbon Remover—The American Oil Products Co., 1426 Seneca street, Buffalo, N. Y., has brought out a carbon remover which will quickly clear away the carbon deposit from the cylinders, it is stated. It is a harmless oil mixture, according to the manufacturer, which penetrates, softens and burns out the carbon. It sells for $1 per quart, this amount be-

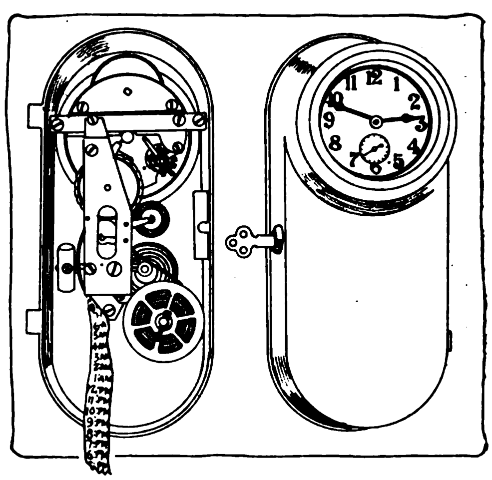

Fig. 3—Hoggson Joyometer for showing when the car is used

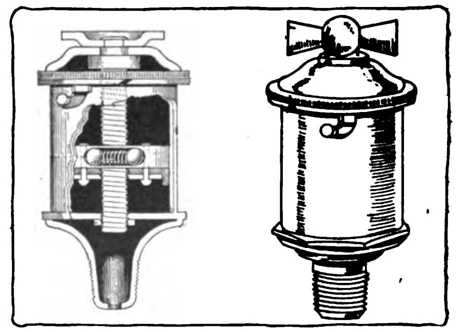

Fig. 4—Climax grease cup with quick detachable top

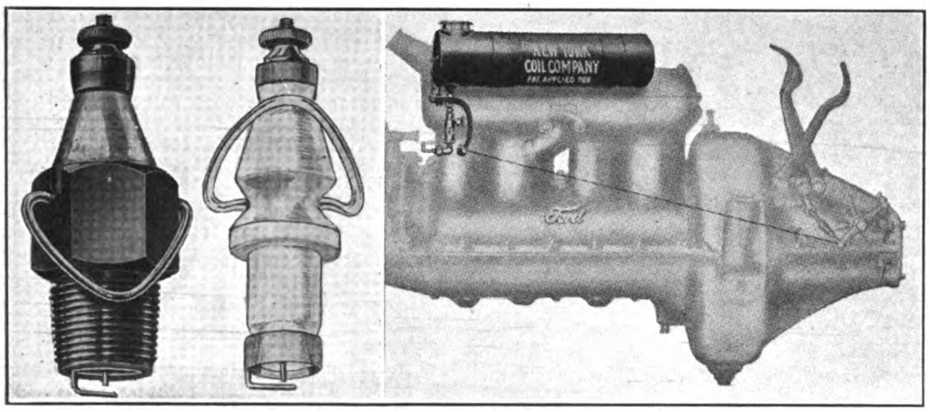

Fig. 5—Left—Bobra quick detachable spark plug. Fig. 6—Right—Ford lubricator made by the New York Coil Co.

ing sufficient for 10 to 15 cleanings.

For ordinary cases the motor is warmed and then about 4 ounces of the remover is put into each cylinder for about 5 minutes, then the motor is started and the carbon is blown out of the exhaust valves. If the motor is badly sooted, the liquid should be left in over night. After the motor is once thoroughly cleaned in this manner it is recommended to put a small amount of the liquid in each week to keep the cylinders clean.

Bobra Spark Plug—A quick detachable spark plug in which the electrode may be removed from the shell of the plug by the simple movement of a wire bail is shown in Fig. 5. It is known as the Bobra and is manufactured by the Bobra Spark Plug Co., Dayton, O. The plug is made in just two pieces, the shell and the insulator. The half-tone illustration shows the plug complete while the dotted line drawing shows the insulator. It will be noted that the two parts of the plug are held together by the eccentric movement of the bail. When the bail is swung up the insulator is rotated a small amount axially when it is free to be lifted out of the shell, the ends of the bail passing up out of the slots in the shell. It is stated that while this fastening is very simple it makes the joint between the two parts perfectly gas-tight.

The advantages claimed for this plug are many. The insulator may be quickly cleaned of deposited carbon or oil, and the points of the electrodes may be instantly inspected and smoothed off. The spark gap may be adjusted by moving the center electrode in or out, but once this adjustment is made there is no possibility of it being accidentally altered by taking the insulator in or out of the shell. Convenient priming of the motor in cold weather is obtained without the use of priming cocks by merely removing the insulator. In this way the plug is of particular advantage to engines such as are used on Ford cars which possess no priming cocks. It is further claimed that manufacturers of automobiles may avoid the expense of priming cocks by fitting these spark plugs.

The Bobra plug is furnished in the three standard sizes, S. A. E., ½-inch standard and metric. The price is $1.

New Lubricator for Fords—A lubricating system, which is designed to work in conjunction with the present system on a Ford car but which has the advantage of maintaining a constant level in the crankcase, is announced by the New York Coil Co., New York. The system

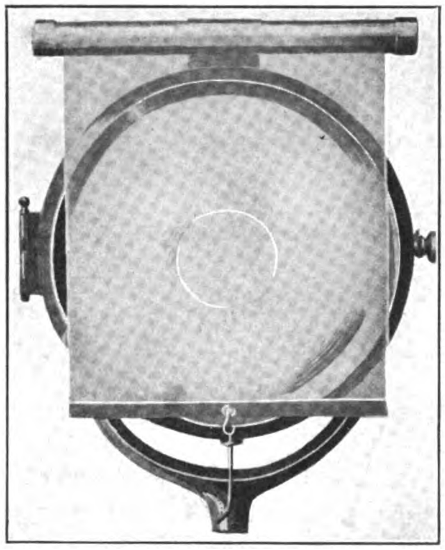

Fig. 6—Safety First headlight shades

operates without the use of gears, belts, rods, etc., and supplies oil to the crankcase at the same rate that it is consumed. The new lubricator consists of a round steel tank 4 inches in diameter and 16 inches long fastened by means of two clamps to the top of the cylinder casting, as shown in Fig. 6. A cock with a long lever is connected by steel wire to the emergency brake.

As it is necessary to apply the emergency brake in order to release the clutch before the operator can leave the car the oiler is automatically stopped, and as the brake must be moved forward to start the car the oiler starts and continues oiling as long as the car is in operation.

A needle valve regulating adjustment is provided, together with a glass sight feed, which is set to deliver oil to the crankcase in the same proportion that oil is consumed by the engine. The regular oiling system performs as usual, but by this attachment the level is kept constant.

A copper tube is supplied with a connection to attach to the oiler; its other end has a fitting adapted to connect to a special hollow bolt, also furnished, which is screwed in place of the bolt that extends through the oil filler spout found on Fords.

The lubricator sells for $10 and it can be installed easily with the use of a wrench in less than half an hour.

Safety First Headlight Shades—For the purpose of toning down the blinding glare of the headlights, Smith Bros., Auburn, N. Y., are marketing a headlight shading device which diffuses the concentrated rays produced by the ordinary headlight lenses.

The device consists of two roll curtains made of translucent fabric which, when down, cover the front of the lamps. When not in use these curtains fold and roll up into suitable cylindrical metal containers attached to the tops of the lamps. Pressing a pedal draws down both shades and locks them in place, and a simple releasing movement allows them to fly back out of the way. The device complete with all fittings costs $10. The construction is such that the parts cannot rattle and are rain and mud proof, it is stated.

Very little light is lost in passing through these shades, the effect being merely to diffuse the rays and not to dim them.

Apex Automatic Electric Tire Pump—A small direct electric driven tire pump, Fig. 7, for the private garage is manufactured by the Apex Electric Mfg. Co., 1410 West Fifty-ninth street, Chicago, Ill. It will inflate a 3 to 3.5-inch tire of ordinary size in 3 to 3.5 minutes.

The cylinders and pistons are accurately ground and lapped together. The piston has two Leak-Proof rings and the bearings are of phosphor bronze and hardened and ground steel. There is an automatic cut-off at the base which shuts off the power the moment the desired air-pressure in the tires is reached. The motor used is a ⅙ horsepower Western Electric. The pump overall measures 13 inches, it is 12.5 inches high and 8 wide. The equipment includes 10 feet of hose and a lamp cord of the same length. The price is $45.

Apex Multiple-Kartridge Electric Soldering Iron—Another device put out by this concern for the automobile trade is an electric soldering iron, known as the Apex Multiple-Kartridge Electric Soldering Iron. It is stated that the electric current keeps the tip at an even temperature. Time is saved because there is none lost in reheating the iron and due to the fact that the tip never scales and therefore no scraping or filing of the tip is required.

The peculiar feature of this iron is the use of different heating elements to give various degrees of heat as are required for different kinds of work. These units are in the form of cartridges and when the temperature is to be changed a new one may quickly be substituted for the one in use.

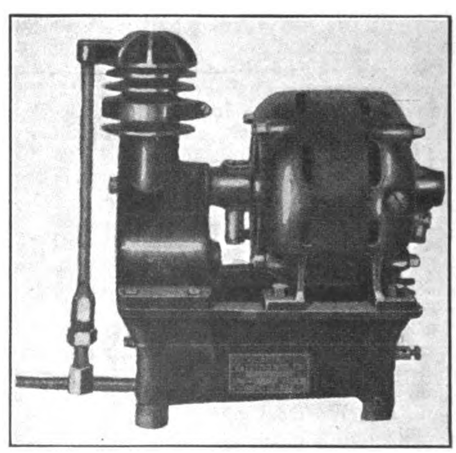

Fig. 7—Apex automatic electric tire pump

VOL. XXXI NEW YORK—THURSDAY, NOVEMBER 5, 1914—CHICAGO No. 19

The AUTOMOBILE

Motor Fortune Wheel in War

No French Factories Destroyed—The Ideal War Truck —Medium-Sized Cars Best—The Rotary Motor Passes

By W. F. Bradley

Special Representative of THE AUTOMOBILE *with the Allied Armies in France*

PARIS, Oct. 16—On the day the Paris automobile salon should have been opened in the Grand Palais, this building was officially inaugurated as a hospital for wounded soldiers. The automobile industry was represented by Marquis de Dion, of the De Dion-Bouton Co. Since the war broke out continuous use has been made of the Grand Palais for military purposes. For several weeks it formed an admirable central garage for cars used as a reserve of the headquarters staff. Later it was used as barracks for the marine fusiliers now stationed in Paris, and has finally been fitted up for hospital purposes.

Not a Car Sold

The general situation in France may be summed up in the remark made to me to-day by the sales manager of one of the leading French car manufacturing firms: "Since first of August we have not sold or delivered a single automobile." He explained that they had partially or fully paid for cars in their shops, but customers would not take possession of them. While it was doing no business in touring cars, this firm was meeting overhead charges by doing such work for the government as making bombs, aeroplane arrows, machine-gun fittings, etc.

This factory is typical of scores in France. There are certain cases in which the war has had no prejudicial influence on automobile firms. The names of several firms might be mentioned from whom the entire stock has been requisitioned by the army authorities, payment being made partly in cash and partly in notes payable after the war. With the entire stock gone, the factory has been shut down entirely and all expense arrested.

No Longer a Luxury

This is sufficient to show that the war does not neces-

War Incidents in France

Not a French factory has been destroyed so far.

After the war the demand will be for medium-sized cars.

The close of the war will be the truck makers' opportunity.

Many French factory organizations are still kept intact.

Organization of Belgian accessory firms entirely disrupted.

A motor convoy under fire is in less danger than horse-drawn wagons.

The ideal motor truck for war is one with a 2½ to 3-ton capacity and four-cylinder motor of 3¾ to 4-inch bore.

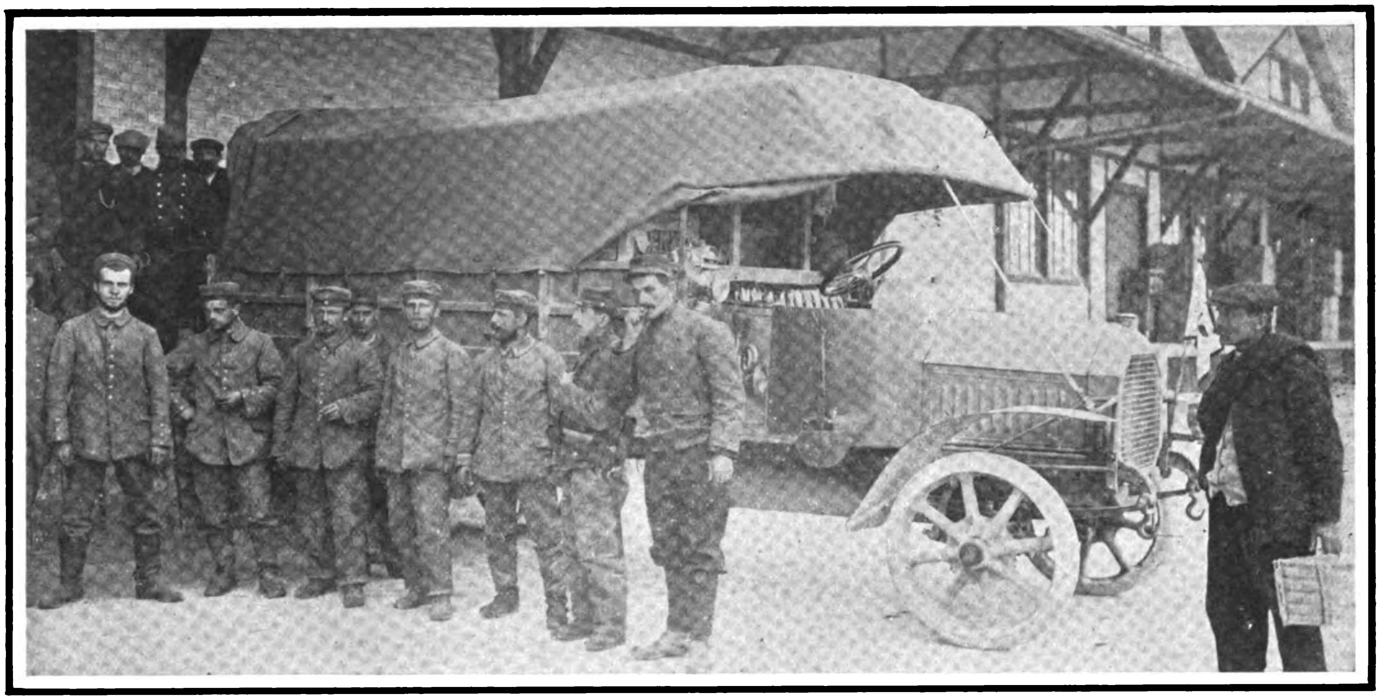
Trucks must have clearance, sprags, towing hooks, four-speed gearbox and interchangeable carbureters and magnetos.

Drain cocks are necessary in cylinders and radiators.

Four-wheel-drive tractors best for artillery work.

Eight-cylinder motors are preferable in aeroplanes.

English furnish best ambulances for field work.



German prisoners being transferred from train to motor truck on their way from the front in France

sarily mean ruination for automobile firms. The tendency to look upon automobiles as a luxury is a mistake which has been clearly revealed during the last 2 months. Manufacturers of articles of luxury have their entire stocks on their hands. Manufacturers of automobiles have been able to clear out their stocks, and if they are not replacing them they are at any rate able to do some useful work for the war department.

THE OPINION IS GROWING AMONG MEMBERS OF THE TRADE THAT THERE WILL BE A RAPID PICK-UP AT THE END OF THE WAR. THE WASTAGE OF CARS IN THIS WAR IS GREAT; THE WASTAGE OF HORSES IS ENORMOUS.

It is only necessary to travel through the country occupied by the armies to realize how the life of cars and trucks is being shortened by rough work and inability to carry out repairs and adjustments at the appropriate time. As to the horses, the shallow trenches in which they are buried, the heaps of them left around unburied and the skeletons on four legs testify to the destruction being wrought among them.

It takes 5 years to breed horses. It takes a few months to produce quantities of cars. There will be a serious shortage of both horses and cars when this grim war comes to a close. The former shortage cannot be met immediately; the latter can. The obvious conclusion is that there will be a big demand for all types of automobiles.

The Truck's Opportunity

IN THE COMMERCIAL FIELD, WHERE TRUCKS WERE FORMERLY USED, THEY WILL BE FOLLOWED BY TRUCKS. THIS IS OBVIOUS. WHERE HORSES WERE EMPLOYED THERE WILL BE EVERY REASON TO REPLACE THEM BY MECHANICAL TRACTION. THE CLOSE OF THE WAR WILL BE THE TRUCK MAKER'S OPPORTUNITY.

It must not be supposed that every vehicle driven by gasoline is going to be accepted by Europe when the guns are silenced. The small cheap car trade is bound to suffer. Those persons who by a little economy have been able to secure for themselves the luxury and convenience of an automobile will undoubtedly forego this mode of locomotion for a certain length of time at any rate. THE GREAT DEMAND WILL BE FOR MEDIUM-SIZE CARS.

BIG HEAVY CARS OF COSTLY MAINTENANCE WILL BE A DRUG ON THE MARKET. FOR SEVERAL YEARS THE EUROPEAN MOTORIST HAS PAID ATTENTION TO THIS QUESTION OF CAR ECONOMY, AND THE WAR WILL ONLY SERVE TO DRIVE HOME THE TRUTH THAT MOTORING MUST NOT BE COSTLY.

Factory Organizations Intact

The main question is, will the factories of Europe be able to meet the demands likely to be made on them. Every manufacturer has been and is doing his best to keep his organization intact. Up to the present the manufacturers of France and England have succeeded. The German invasion has not yet touched the French motor car area.

AT THE TIME OF WRITING NOT A SINGLE FRENCH MOTOR CAR FACTORY HAS BEEN DESTROYED OR EVEN DAMAGED.

Parts Area Suffers

Probably the same cannot be said of Belgium. Unfortunately, also, the various industries on which the automobile manufacturer has to depend have suffered more than the automobile industry itself. The whole of the north of France and a considerable portion of Belgium supply steel and iron castings, forgings, steels and raw materials for the French and British automobile trades.

I have information of several firms having sent thousands of dollars worth of patterns into Belgium and Germany before the war and now faced with the loss of this valuable material. As in most cases, it will be impossible to regain possession of these patterns; new ones will have to be made. A busy time for pattern makers is certain.

A REVIEW OF THE SITUATION AT THE PRESENT TIME FORCES TO THE CONCLUSION THAT THE RAPIDITY OF THE PICK-UP WILL DEPEND MORE ON THE SUPPLY FIRMS THAN ON THE AUTOMOBILE MANUFACTURER PROPER.

It is interesting to note what influence this war will have on war equipment. With a really decisive result, the probability must not be overlooked of an all-round diminution of armaments—a throwing off of the burden of militarism under which Europe has so long groaned. This will only modify the extent and not the nature of the change in military equipment. Cavalry will not be affected by the automobile; but every other army service has already been completely transformed by mechanical transport.

In the army service corps horses are still being employed for bringing up food and ammunition, but their services would be dispensed with if it were possible to do so at once.

Horses Not Needed

WITH THE ALLIED TROOPS I HAVE SEEN HORSES STANDING IDLE DAY AFTER DAY—GOOD HORSES DRIVEN BY MEN WHO KNEW THEIR BUSINESS — WHILE THE MOTOR TRUCKS WERE KEPT ON A DAY AND NIGHT SERVICE. IT HAS BEEN CONCLUSIVELY PROVED THAT HORSES ARE NOT NECESSARY, INDEED THAT THEY ARE PREJUDICIAL TO THE BEST WORK OF AN ARMY SERVICE CORPS IN THE FIELD.

Officers, with a blind faith in horseflesh, have been very slow to admit this. The old argument was put forth that motor vehicles would break down and for lack of some little screw, nut or bolt would be entirely lost. Spare horses, on the other hand, could always be had, and if an animal went lame it would quickly be replaced.

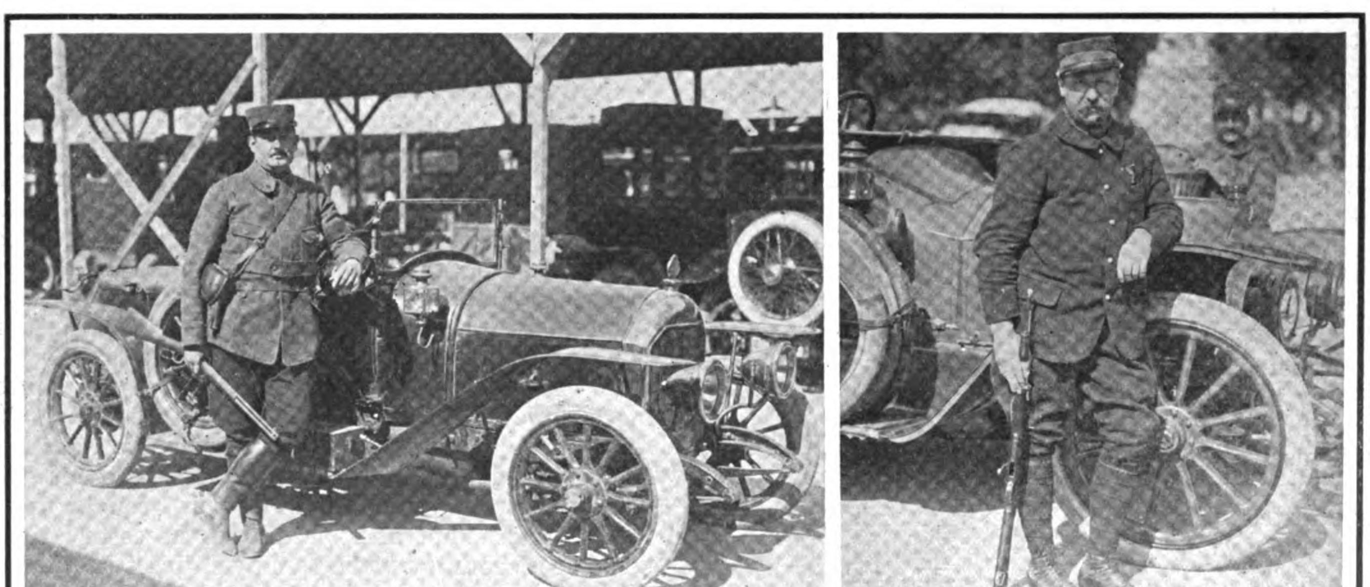
Thus, at the opening of the war the arrangements were for motor trucks to carry ammunition and food from the railhead to a point a certain distance back of the firing line and make the final distribution by means of horse-drawn army wagons. This plan has been abandoned. The transfer caused a loss of time and the final distribution by horses was far less reliable than a direct delivery by motor. Thus, whenever possible, the horse has been cut out of this service altogether. It is practically immaterial whether the railhead be 10, 20 or 30 miles behind the firing line, for the trucks can be relied to come right up with unfailing regularity.

Trucks Under Fire

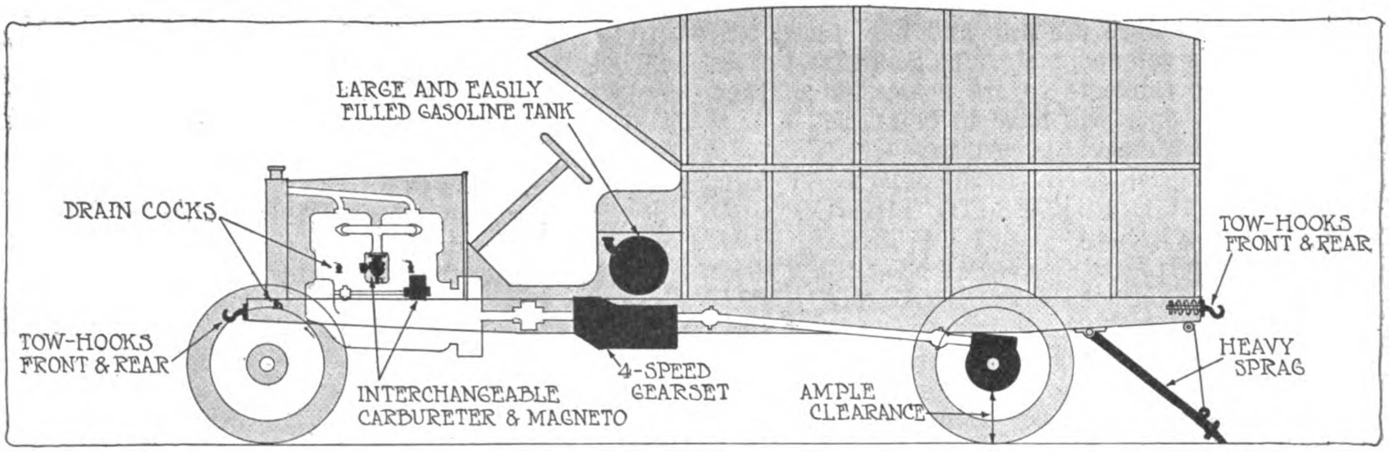
A motor convoy under fire is in less danger than a number of horse-drawn wagons. A great proportion of the horses used in the army service corps are taken direct from peaceful occupations, and are naturally scared at the tremendous roar of modern guns. It is impossible, without entering into ghastly details, to describe the confusion caused in a column by a few horses struck by bullet or shell. Although the motor truck has not been made bullet-proof, it is surprising how difficult it is to put it out of business. I have seen trucks speckled all over with shrapnel without having their running qualities in the least affected. Compared with a horse, the modern motor is a very small target, and unless a bullet strikes the cylinders or goes through the radiator the vehicle is not likely to be incapacitated.

The Ideal Vehicle

THE MOST SUITABLE TYPE IS A VEHICLE CARRYING A USEFUL LOAD OF 2½ TO 3 TONS, DRIVEN BY A FOUR-CYLINDER MOTOR OF 3¾ TO 4-INCH BORE. THE IMPORTANCE



Left—D'Avaray, a competition driver for Buick, doing service for the French Army on a Pierron car. Right—Arthur Duray, winner of second place in last Indianapolis race, now in military service with the French army



Illustrating the requirements brought out as necessary in the construction of motor trucks for military service by the experience gained during the fighting in France

OF CERTAIN FEATURES HAS BEEN FULLY EMPHASIZED DURING EVEN THE SHORT PERIOD THE WAR HAS BEEN IN PROGRESS. THESE ARE ADEQUATE CLEARANCE, STOUT SPRAGS AS A PRECAUTION AGAINST RUNNING BACKWARDS, TOWING HOOKS FRONT AND REAR, THE ABILITY OF EACH TRUCK TO TOW ANOTHER OF EQUAL WEIGHT OVER ORDINARY ROADS, FOUR-SPEED GEARBOXES WITH A LOW EMERGENCY GEAR, INTERCHANGEABLE CARBURETERS AND MAGNETOS, EASILY FILLING AND EMPTYING GASOLINE TANKS, DRAIN COCKS FOR CYLINDERS AND RADIATORS.

Trucks Must Tow

This question of towing ability is really important. It is an everyday occurrence for a truck to be temporarily disabled. If it can be got back to headquarters a few hours' work will put it in full running condition. If, on the other hand, a tow is not immediately available the vehicle may have to be destroyed or fall into the hands of the enemy.

Big capacity gasoline tanks are an important feature. There has never been any permanent shortage of gasoline among the allied troops, but it frequently happens that unusually long journeys have to be made without any possibility of renewing the fuel supply. The more gasoline a truck can carry without in any way interfering with the useful load, the better.

Provision should also be made for a reserve supply. A tank which can be quickly emptied is a valuable feature. I have had several experiences as follows. English drivers have asked on the wayside for petrol, which is the French word for kerosene. They have been given exactly what they asked for, with the result that a few hours later they found themselves stranded with fouled plugs and a spluttering motor. To get the kerosene out of the tank not fitted with a special drain-off cock is a longer job than one would imagine.

Bad Water Connections

Up to the present really severe weather has not been encountered. Nevertheless it has been sufficiently cold to remind us that frost will have to be feared and radiators and waterjackets emptied. Looking into this matter, I have been struck with the fact that it is sometimes absolutely impossible to get the water out without breaking one of the rubber connections. In the shops it would not be a difficult matter to fit drain cocks in the base of the radiator; but there is little time and few conveniences for carrying out such work at the front.

Two Hours to Start

Already the cold weather is making it a difficult matter to start up in the morning. Before all the motors in one convoy to which I was attached had been wound up 2 hours had been lost. This incident occurred after a very cold damp night spent out of doors. When benzol and alcohol have to be used the difficulties are so much greater that permanent provision should be made for warming up the carbureter before attempting to crank.

There has been no necessity in this war to work entirely away from made roads. Thus there is no necessity for anything more than a liberal clearance.

Four-Wheel-Drive Tractors

It is quite probable that after this war there will be an entire reformation of the artillery service, four-wheel-drive tractors being used in place of horses. At the present time horses do the bulk of the work of hauling guns. The French, however, are using tractors for their 155-millimeter guns and obtaining such good service from them that they are certain to be extended. The advantages of mechanical over animal traction in the commissariat department are amplified in the artillery service. The future points to guns without horses, for a four-wheel drive tractor can do all, if not more, than a team of horses; it is not so vulnerable and it can be more rapidly replaced.

All-drive tractors are also a valuable auxiliary for bringing up ammunition. At the present time the great bulk of the ammunition is brought up on motor trucks, but as it is always necessary to do some cross-country work to travel direct to the batteries, a four-wheel-driver has a decided advantage over a vehicle alive at only one end.

This war had not been in progress many days before it was evident that the allies were short of automobile guns. The Germans, who were supposed to possess a smaller number of automobiles than the French and English, had not overlooked the importance of mounting their medium-sized guns on automobile chassis. Caliber for caliber, a gun mounted on a chassis is infinitely superior to one drawn by horses. An automobile battery will remain in position until the last possible moment. When it is about to be attacked at close quarters it will get away beyond the possibility of pursuit.

THE VALUE OF THIS ARM HAS BEEN SO CONCLUSIVELY DEMONSTRATED THAT BOTH THE ENGLISH AND FRENCH HAVE PLACED BIG ORDERS FOR AUTOMOBILE GUNS SINCE THE WAR BROKE OUT.

In very many cases ordinary 2½-ton chassis are being made use of, the fitting of the gun being carried out by the arsenal. While this makes a valuable weapon, better results are obtained with a specially designed chassis having provision against the recoil of the gun and a certain amount of armor plating.

Much use has been made of armored automobiles for rapid invasions into the enemy's country. Two or three such machines sent out to explore the country are practically invulnerable and most effectively prepare the way for the advance of more important bodies.

Eight-Cylinder Motors Best

I am not particularly interested in the aeroplane as a weapon of offence and defence. Even military experts are not unanimous regarding the services it has rendered. The aeroplane motor question, however, has its bearing on the automobile.

THERE IS A GROWING OPINION AMONG AVIATORS AND AEROPLANE MECHANICS THAT THE FIXED TYPE OF MOTOR IS PROVING MUCH MORE VALUABLE THAN THE VARIOUS ROTATING CYLINDER MOTORS. THE GREAT OBJECTION BROUGHT AGAINST THE ROTARY MOTOR IS THAT IT REQUIRES MUCH MORE ATTENTION THAN CAN BE GIVEN IT UNDER WAR CONDITIONS.

Trials and manoeuvres are so entirely different from actual warfare that it has required the events of the last 2 months to reveal the weaknesses of the rotary motor. The two leading types of eight-cylinder V motors, made by De Dion Bouton and Renault, have been conspicuous for the service they have rendered and the small amount of attention they have required. This is important at the present time, for the De Dion Bouton eight-cylinder aviation motor is practically identical with the eight-cylinder car motor produced by that firm.

Gasoline Tanks Too Small

Touring cars have given all that was expected of them and considerably more than most people hoped. The main faults I have noted against touring cars on military service is the inadequacy of the accommodation for spares, tires, gasoline and spare gasoline supply. For this work cars should have a capacity of 200 miles without refilling the gasoline tank.

WITHOUT LITTERING THE BODY IN ANY WAY, IT SHOULD BE POSSIBLE TO CARRY 2 GALLONS RESERVE GASOLINE, 1 GALLON RESERVE OIL, TWO SPARE SHOES, FIVE OR SIX TUBES, A BIGGER SUPPLY OF TOOLS THAN USUAL AND A MODERATE SELECTION OF SPARE PARTS.

It is surprising how few cars can stow these things away without infringing on the passenger-carrying space. Very few actual defects can be charged against the cars in the field. Certain makes of cars built for good road conditions have suffered from spring trouble, but this is not a general complaint.

Small Cars Best

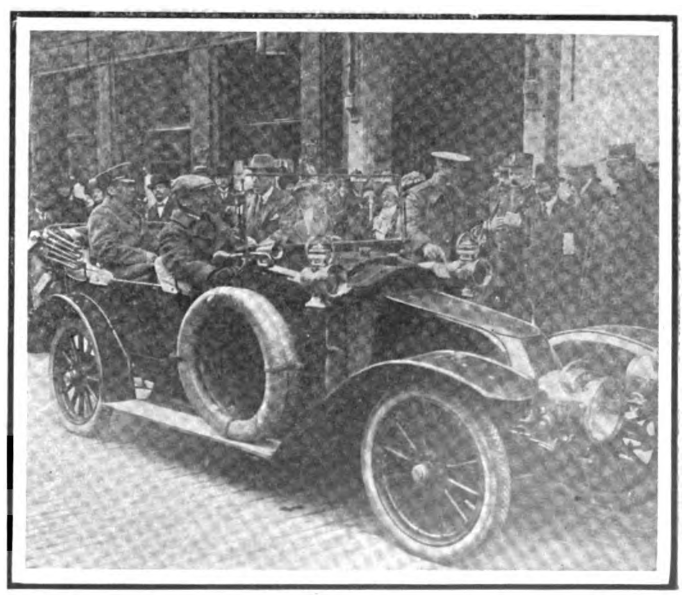
While the cars themselves have generally been satisfactory, their method of employment has often left much to be desired. The fast, powerful touring car is not the most suitable vehicle for work near the firing line. Crack motorists who have been given 70 and 90-horsepower cars have soon discovered that they could get better service out of 15-horsepower machines than out of the semi-racing models.

At the front the roads are encumbered; all the power available cannot be used; a heavy car embedded in mud or dropped into a ditch is much more difficult to move than a lighter machine.

For work right at the front much better results are being got out of four-cylinder touring cars of approximately 3 by 5 inches bore and stroke than out of machines of double that size.

Fast Cars for Dispatches

The proper place for very powerful extra rapid cars is on the open road, carrying officers or dispatches from the front to the base or the government headquarters. For instance, at the present time the French government is at Bordeaux, 400 miles from the firing line. All the dispatches are carried between the two centers by two relays of cars, the first driver covering 200 miles, then handing his dispatches over to a second driver waiting at the half-way position. With 70 and 90-horsepower cars this



Earl Fitzwilliam, head of the mechanical transport service of the British army, leaving Paris for the front work can be done faster than by trains under peace conditions.

Many Poor Drivers

The suitability of the driver for the car he is handling is another important matter. When cars have been requisitioned from factories, not enough attention has been paid to the question of getting drivers from the same factory. It is obviously advisable for a man who has spent 10 years of his life tuning up Panhard cars to be put at the wheel of a machine of this make rather than a Peugeot, a Renault, or any other. In the main this has been done, but there are nevertheless some glaring inconsistencies.

Gabriel, who has probably driven cars longer than any man living, has been pushed into a line regiment.

Louis Wagner, one of the most skilled and daring drivers alive, as well as an experienced aviator, is a private in an artillery regiment.

The famous Jules Goux was wasting his talents in a fort for a couple of months before he was given a car.

Jean Chassagne, the man who has driven further in 1 hour than any person dead or alive, has not been allowed to touch a car since war was declared.

On the other hand, could be mentioned chief engineers and heads of testing departments who are riding on trucks as private soldiers while some non-technical man is at the steering wheel. This is a phase of motor application to war which must be given the closest attention if best results are to be obtained.

Good English Ambulances

Little criticism can be levied at the quality of the motor ambulance work of the British army, although its quality might be improved. The method is for motor ambulances to go as close to the firing line as possible, load up with the wounded brought in by the stretcher men and carry them to the railhead or general headquarters, where they are tended in temporary hospitals, which are frequently nothing better than churches, barns or railroad stations. From this point the wounded are carried to the rear by trains and finally distributed among the hospitals by more motor ambulances.

The type of ambulance most generally used at the front is a 20-horsepower touring-car chassis fitted with a large capacity canvas body with mica windows. The body is of sufficient size to carry four stretchers in two tiers, leaving a space down the center for the ambulance attendant.

Most of these vehicles have been supplied by the Wolseley company, and are the pick of the British fleet. There are other and more hastily prepared ambulances carrying six men in two vertical rows of three. With such a load it is practically impossible to give any attention to the men when on the move, while loading and unloading present greater difficulties.

The French system of slinging stretchers inside the closed trucks which are returning from the firing line to the rear has the advantage of getting the men away quickly, but it offers little in the way of comfort.

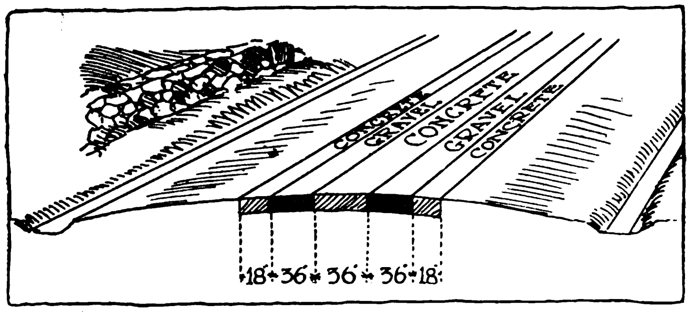
One Failure

The great defect in the general organization is the inadequacy of the motor system for removing men from the hospitals just to the rear of the firing line. Frequently wounded men have to spend 15 to 20 hours lying on straw in a freight train, when touring cars could bring them back in 3 to 4 hours. The army does not possess these cars, but hundreds of private individuals and several private associations would be glad to undertake the work, and indeed have undertaken it to a limited extent. Why this work is not carried on on a bigger scale and in a more effective manner it is difficult to say. There is no doubt that the car is infinitely superior to the railroad for this task.

Michigan County Makes Highway Like Railroad

THE influence of railroad practice is noted in an experimental road being tested in Kent county, Mich. The wear and tear of traffic is taken by strips of concrete, the space between the strips being separated by gravel. Three strips are used, the center one being twice as wide as the other two and intended to be used in common by traffic in both directions.

As will be noted in the accompanying illustrations, the two outer strips are 18 inches in width while the center one is 36. The bands of gravel between the concrete are 36 inches in width. The total breadth of the roadway is 9 feet 4 inches. The two intermediate widths are composed of gravel cemented into place with glutrin.



Method of constructing road in Kent County, Mich., designed especially to prevent ruts. It costs $3,000 per mile

The inventor of this new construction is Alvah Brown, one of the commissioners of Kent county. He explains that the natural inclination of horses is to follow the rut and it is therefore necessary to design a road which will withstand heavy wear without forming ruts and which will not at the same time involve heavy construction cost.

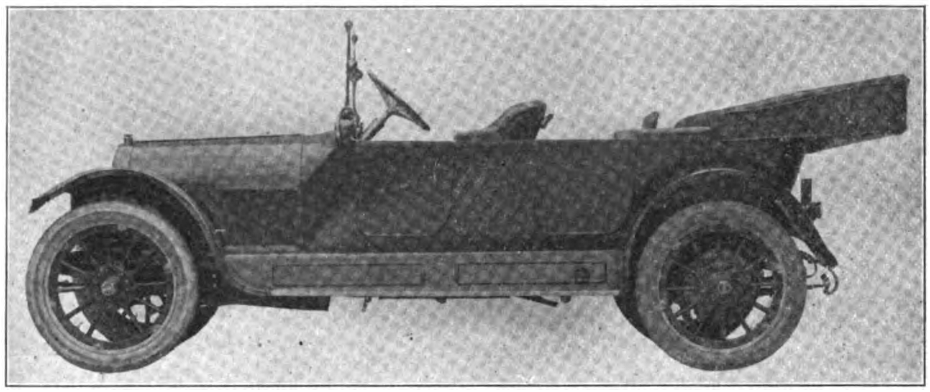
In commenting upon his method, Mr. Brown says:

"It is no more necessary to have the entire portion of the roadway cemented than it is to have iron spread the full length of the ties on a railroad. All that is necessary is narrow hard surfaces for the wheel treads and these, being built according to my design, will be dustless and meet all requirements for modern traffic. Every 30 feet each strip of concrete will have an expansion joint with metal strips therein, so the concrete ends at joints will not be broken by steel tire vehicles.

"After the roadbed has been graded and settled, this class of road can be built complete, including concrete and glutrinized gravel, for about $3,000 per mile.

Seven-Passenger Overland Six $1,475

New Block Motor 3 1-2 by 5 1-4 —Electric Starting and Lighting— Equipment Is Unusually Complete

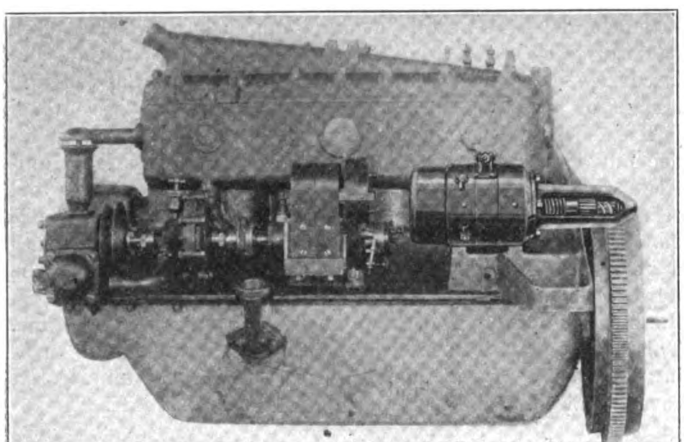


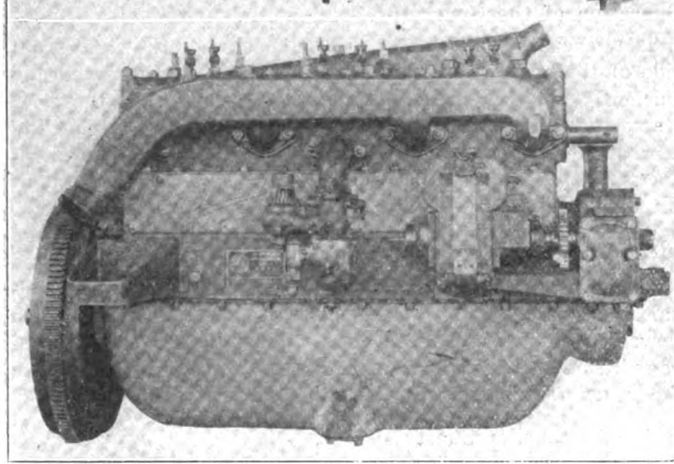
Six-cylinder, seven-passenger Overland touring car which sells for $1,475 with electric starting and lighting and complete equipment

ALTHOUGH the Willys-Overland Co. told the public in June that it would have a six-cylinder car bearing the Overland name on the market early in the fall, it did not make known any of the details at that time. Now the fall is at hand and so is the new Overland, the first six that the big factory has ever turned out.

Seven-Passenger Body Standard

Only the one body type is offered, a seven-passenger design which has the same general outward appearance as the four-cylinder Overlands, being a smooth-sided model with clear running boards, domed fenders conforming closely to the curve of the wheels, and cowl sloping in graceful curves to the bonnet, which also has a slight slope to the radiator. Like the rest of the Overlands of the year, the radiator is specially attractive, being of the rounded-edge type with the shell pressed from one piece of sheet steel.





Views of both sides of the block motor used in the new Overland six. The valves are all on the right, inclosed by aluminum cover plates which are easily removable. Note mounting of electric starting and lighting system

The price has been set at $1,475 with complete fittings ready for the road. There is an electric cranking and lighting system, besides an unusually complete list of equipment including speedometer; rain-vision, ventilating windshield; mohair one-man top and top boot; electric horn; demountable rims with one extra; tire carriers in the rear; robe rail; foot rest; tools, tire repair kit; jack and pump. Tires are 35 by 4 1-2 inches and the rear pair are of the non-skid variety.

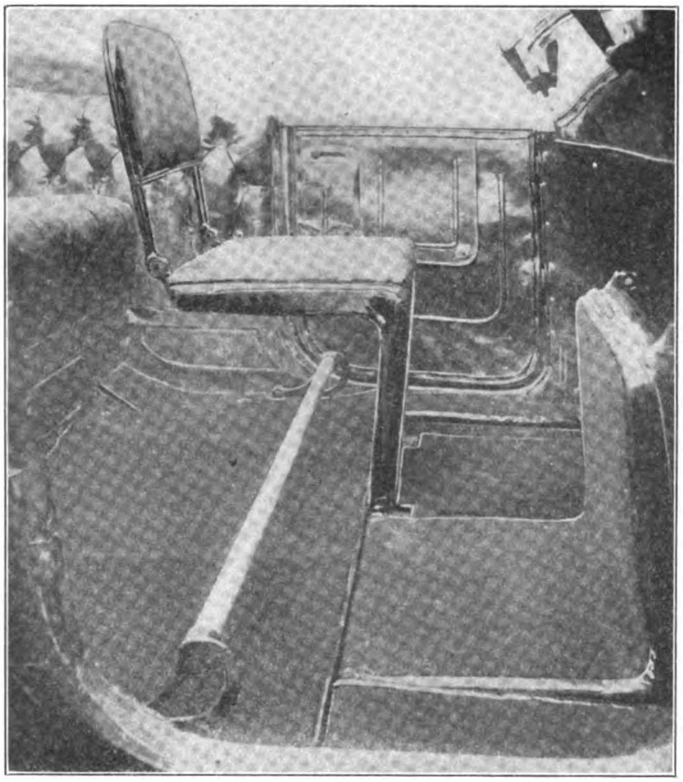
New Long-Stroke Block Motor

While the general mechanical construction of the chassis is in accord with Overland design as practiced in the four-cylinder models, the motor of the six is new to Overland engineering. It is a block-cast type having a bore of 3 1-2 inches and a stroke of 5 1-4 inches. The cylinder head is detachable as a unit and the upper half of the crankcase carrying the crankshaft is a part of the cylinder casting. The lower half attaches at about the center line of the bearings and thus an advantageous adaptation of the detachable cylinder head design together with the better manufacturing proposition brought about by making part of the crankcase integral with the cylinder casting, is worked out.

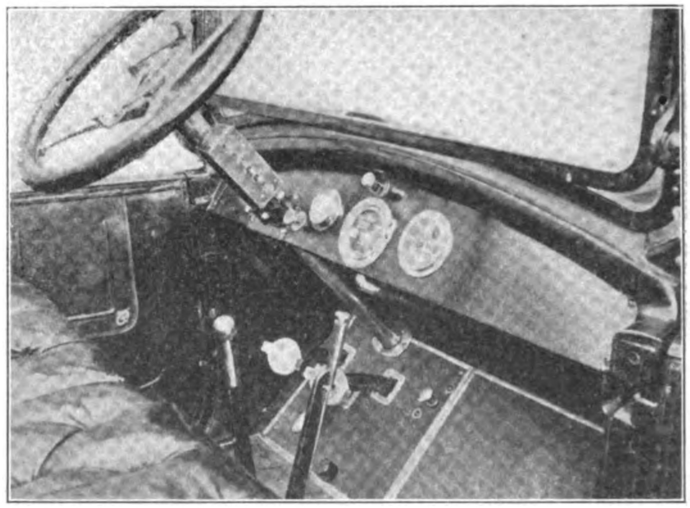
The stroke is quite long in comparison with the bore, the ratio being 1.5 to 1, and with this relation the developed horsepower is greatly in excess of the S. A. E. formula rating of 29.5 horsepower. According to the maker, the engine produces 45 to 50 horsepower in test in very excellent fashion and with a striking absence of vibration. The piston displacement figures to approximately 303 cubic inches.

Rear Axle Gearbox

Although the gearbox is not in unit with the motor, it being a part of the rear assembly as in all Overland cars, the motor is of the three-point suspended type with substantial arms integral with the cylinder block casting running outward to the chassis supports just forward of the flywheel. The front end rests upon a cross arm by means of a form of foot also integral with the cylinder casting. Two bolts, one either side of the bearing in the supporting member for the crank-handle shaft, fasten the motor in place in front; this mounting really serving as a single-point construction. The arrangement may be seen in the motor view.



Illustrating the manner in which the auxiliary seats in the tonneau of the seven-passenger Overland six fold into the back of the front seat



Driver's compartment of the new Overland six, showing left drive and center control, together with mounting of instruments on cowl board

The valves are all on the right side, and are neatly housed by two aluminum plates held in place by five set screws each. There are four openings from the exhaust ports to the exhaust header, two for each set of three cylinders. But there is only one opening from the casting to the intake pipe running from the carbureter. This is at the center of the casting just below the exhaust pipe, the distribution to the several intake pockets being accomplished by cored passages within the casting itself. This serves to aid vaporization of fuel because the gases are heated by the jacket water around the cored passages.

The cylinder head, which is held in place by a number of steel bolts, carries the water outlet connection to the radiator as an integral part, holds the spark plugs and priming cups. This head when removed exposes cylinders, pistons, valves and valve chambers.

Spiral Gearing Much Used

The drive for the camshaft, magneto, pump and generator is unusual in that spiral gearing plays an important part. A transverse shaft, spirally driven from the crankshaft in turn drives the magneto and pump shaft on the left side by spiral connection and the generator on the right side by the same type of gearing. The camshaft is also spirally actuated from the same shafting, all of which is completely housed at the front of the motor. This makes a very compact and well-balanced design which should be very silent in operation.

Accurate Balance and Light Weight

Accurate balance of reciprocating parts is also a feature of the motor, and vibration is reduced to the minimum not only by this means but also by reducing the weight of the reciprocating parts as much as possible so as to be consistent with the strength required. The crankshaft which is substantially mounted on three main bearings is manufactured to very close limits, while the camshaft, carried on four bearings, is also very strong.

The lubrication of the motor is of the constant level splash type in connection with pressure feed to the main crankshaft bearings. The oil base is in the bottom of the crankcase, and the pressure pump forces the oil from it to the main bearings and also the connecting-rod troughs, individually placed under each cylinder and the oil from them being thrown to the various bearing surfaces from the ends of the rods. The lubricant drains back to the crankcase reservoir for recirculation after straining.

Cellular Radiator

Cooling is very efficient and employs a centrifugal pump mounted ahead of the magneto and operating from the same shaft. Its cooling work is augmented by a good-sized fan which is belt driven from a pulley on the pump shaft. The radiator is of the cellular type with vertical circulation, and is carried on swivel trunnions which allow for the twisting strains of rough travel.

The electric lighting and cranking system is entirely independent of the Bosch high-tension magneto used for ignition. Cranking motor and generator are separate units and occupy positions on opposite sides of the engine. The electric motor connects to the engine for cranking purposes through a gear meshing with the teeth cut in the outer rim of the flywheel, a pedal when pressed sending current to it from the storage battery and meshing the gears at the same time. This cranking unit is very powerful and is capable of turning the engine over at about 140 revolutions per minute. It revolves at 11.33 times the speed of the crankshaft.

Operation of the Generator

The generator which rests upon a bracket on the right front side of the engine is driven at 1 1-2 times engine speed and efficiently charges the 80 ampere-hour storage battery. It starts to send current to the latter when the car is traveling at about 8 miles an hour and reaches its maximum output at about 25 miles an hour car speed. The electrical system is of the 6-volt, single wire type, which is the simplest possible.

Leaving the motor, the next step in the power transmission is the cone clutch which is leather faced with spring-pressed studs under the clutch facing, these insuring easy and gradual engagement. A clutch brake is also provided which serves to stop the released cone from spinning when disengaged, this being an advantage for easy gear shifting, since the gears are not spinning to clash when meshed.

Inclosed Propeller Shaft

Regular Overland practice is seen throughout the balance of the chassis in the inclosed propeller shaft with universal joint at the front end, and the torsion tube surrounding it having a yoked front end hinging to a cross member of the frame at either yoke arm end. The torsion tube terminates in a flange which bolts to a mating flange on the front end of the compact gearbox. This latter bolts through another flange to the differential housing so that axle, drive members and gearset are all one unit. Strong radius rods run from the front end of the tube to the outer ends of the axle tubes as a strengthening feature.

Three-Speed Gearbox

The gearset is of the selective, sliding-gear type giving three speeds forward and reverse. The gears are of ample proportions, made of double heat-treated nickel steel and having strong stub teeth. The shafts are carried on annular ball bearings. This gearset is a special design for the six chassis, though conforming to the same general construction as that used for the other cars, only having larger bearings, and so on.

The rear axle is a floating design in which the car load is carried on the axle tubes and the shafts within are used for the sole function of driving the wheels. These shafts are removable, connecting to the differential conventionally by means of splines. The differential consists of the usual four bevel gears within the ring gear. Adjustable taper roller bearings are used throughout, there being two in each wheel and two for carrying the differential. The axle ratio is 4 to 1, which should give the car plenty of pulling power.

The brakes are large and powerful and said to be ample for a much heavier car. However, such factors of safety are commendable for no part of the car is of more importance than the brakes. The contracting service brakes measure 14 3-8 inches in diameter by 2 1-4 inches wide, while the expanding emergency pair are 14 by 2 1-4 inches.

Rear Springs Are Underslung

The spring suspension is well taken care of by the conventional half-elliptic front springs and three-quarter elliptics in the rear. Leaves are 2 inches wide, while the front length is 38 inches, and the rear 52 inches. To bring the suspension lower down and add to easy riding qualities, the rear springs are slung under the axle and have swivel seats. The maximum freedom of motion is thereby attained. These springs are attached outside of the frame rails by means of gusset plate construction and their rear ends are of the scroll form.

Left Drive and Center Control

Control of the car is standard in every respect, excepting that all control buttons for horn, magneto, starter and lights are conveniently located in a switch box attached to the steering column, just below the wheel. Drive is on the left by means of an 18-inch steering wheel operating a worm and full gear type of steering mechanism, while center control is also featured. The spark and throttle levers occupy the usual position on the steering wheel quadrant above the spider, while the various gauges and dash instruments are conveniently arranged on the cowl dash, those requiring to be reached when in driving position being nearest the drive seat.

The wheelbase of the newest Overland is 125 inches, 19 inches longer than that of the model 81 small four, and 11 inches greater than the larger four, model 80. Tread is standard at 56 inches.

Vacuum Feed Fuel System

Although the gasoline tank is placed under the front seat, making gravity feed to the carbureter very reliable, the new Overland makes assurance doubly sure by the use of the Stewart vacuum feed system with the vacuum tank mounted on the front of the dash. This makes the carbureter supply positive under all driving conditions such as steep hill work and the like. It raises the level of the fuel going to the carbureter about 6 inches above the main tank level.

The principal motor specifications follow:

Camshaft diameter	1 1-4 inches
Camshaft bearing, front	2 1-4 by 2 3-4 inches
Camshaft bearing, No. 2	1 by 2 3-16 inches
Camshaft bearing, No. 3	1 by 2 1-8 inches
Camshaft bearing, rear	1 1-2 by 2 1-16 inches
Connecting-rod, length	9 3-8 inches
Connecting-rod bearings	2 by 2 3-16 inches
Crankshaft, diameter	2 inches
Crankshaft bearing, front	2 3-16 by 3 inches
Crankshaft bearing, center	2 7-32 by 2 1-2 inches
Crankshaft bearing, rear	2 1-4 by 3 inches
Piston, length	3 3-4 inches
Piston pin bearings	1 1-16 by 1 1-2 inches
Piston rings, three, width	3-16 inch
Valve, diameter	1 13-16 inches
Valve stem, diameter	3-8 inch

Form American Drop Forge Association

DETROIT, MICH., Nov. 2—About twenty representatives of some of the largest drop forge manufacturing concerns in Michigan, Ohio, Indiana, Virginia and Canada, met at the Ponchartrain recently and took the preliminary steps towards the organization of what has been temporarily named the American Drop Forge Assn.

The object of the new body is to get together for the purpose of business, pleasure and good fellowship.

The following temporary officers were elected: R. R. Ellis, superintendent Detroit Forging Co., president; George Desautels, manufacturing manager, Anderson Forge & Machine Co., vice-president; A. E. Dibble, department manager, Frost Gear & Machine Co., Jackson, Mich., secretary; E. B. Horne, forge and foundry superintendent, Packard Motor Car Co., treasurer.

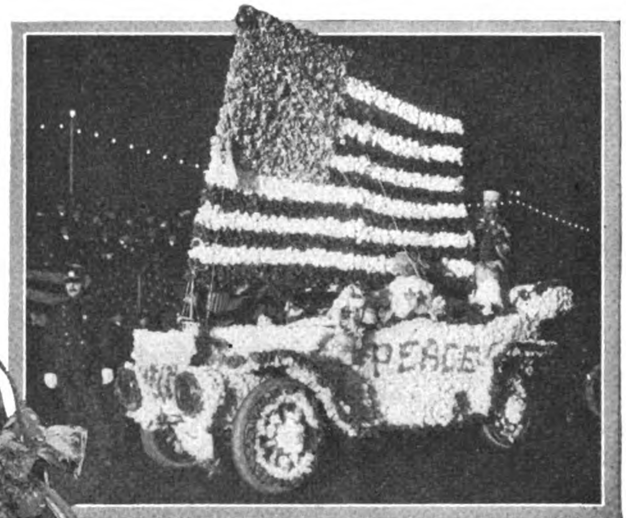
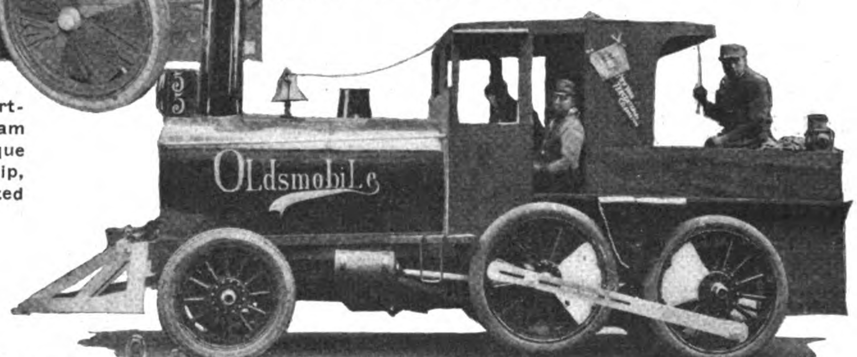
New York's Tercentenary Pageant

Veteran Cars and Novel Decorations Win Many Prizes



Above—Peace float of C. B. McCoy, Jr., Philadelphia, Pa., which was awarded the $500 first prize for the best decorated car

Above—Autumn decorated Waverley, Poertner Motor Car Co. Right—Oldsmobile steam engine, $200 first prize winner in Grotesque division. Below—Oldsmobile Christmas ship, which took $200 prize as second best decorated car



NEW YORK CITY, Oct. 30—The Automobile Pageant of New York City's Tercentenary Celebration, which was held Wednesday night, was a great success.

Many unusually well decorated cars and trucks were in line and great originality was shown by the dealers, clubs and individuals participating. The list of prize winners as officially issued, is as follows:

DIVISION A—Early Models—Oldest car completing the line of march under its own power. First Prize, $100, Joseph Devantry, Brooklyn, N. Y., 1899 Panhard. Second prize, $50, Oldsmobile Company of New York, 1898 Oldsmobile.

For best appearing car operating under its own power built during the period of January 1, 1902 to December 31, 1905. Third prize, $25, Harrolds Motor Co., 1902 Pierce-Arrow.

DIVISION B—Grotesque. First prize, $200, Oldsmobile, Steam Engine. Second prize, $100, Fleischmann Company, John Dough. Third Prize, $75, Michelin Tire Company, Bibendum Twins. Fourth prize, Douglas Fairbanks, He Comes Up Smiling, Bathtub Float.

DIVISION C—Pleasure Car—Class 1. Best decorated car. First prize, $500, C. B. McCoy, Jr., Philadelphia, Peace Float. Second prize, $200, Oldsmobile Co. of America, Christmas Ship. Third prize, $100, Allen Auto Specialty Co., Autumn Float. Pleasure Car—Class 2. Best decorated runabout. First prize, $250, John W. Cleary, Brooklyn, N. Y., Oriental Pagoda. Second prize, $100, Poertner Motor Car Co. Class 3—Regularly established club with the highest rating of points. First prize, $200, Long Island Automobile Club. Second prize, $100, Automobile Club of America. Third prize, $75, Bug Club of Harlem. Class 4—Dealer having the greatest number of cars of one make represented by him in a division. First prize, $200, Ford Motor Co. Second prize, $100, Chevrolet Motor Co. Third prize, $75, Brady-Murray Motors Corp., Chandler.

DIVISION D—Commercials. Class 1—Best decorated commercial car. First prize, $500, New York Sporting Goods Co., Indian Motorcycle Float. Second prize, $200, Edward Callen

Third prize, $100, Max Schling. Class 2—Merchant entering the largest fleet of commercial trucks as owned and operated by him. First prize, $200, Loose-Wiles Biscuit Co. Second prize, $100, New York Edison Co. Third prize, $50, Ward Bread Co. Class 3—Dealer having the greatest number of commercials in one division. First prize, $200, Autocar Co.

DIVISION F—Advertising. Best appearing vehicle carrying advertising other than merely name and address of owner regularly used in service. First prize, trophy valued at $150, Omar Cigarettes. Second prize, $100, Bull Durham Tobacco. Third prize, $75, Atlas Cement Co.

Special prizes donated by various individuals were allotted as follows: Silver Cup by J. Sanford Saltus, for the best French car, awarded to Emanuel Lascaris, DeDion-Bouton car. Other special prizes for the automobile division were the Hub Odometer, Brown Oil Boxes, Automobile Club of America. The odometer given by the Veeder Mfg. Co. was awarded to Doelger Brewery Co. for the largest fleet. The Brown oil box donated by the Brown Trafilog Co. to the Vivandière car. The Automobile Club for long distance mileage. Special mention, the Grotesque Class, Tipperary Float and Baby Olds. Dealers' Window Display prize, $100, Firestone Tire Co.

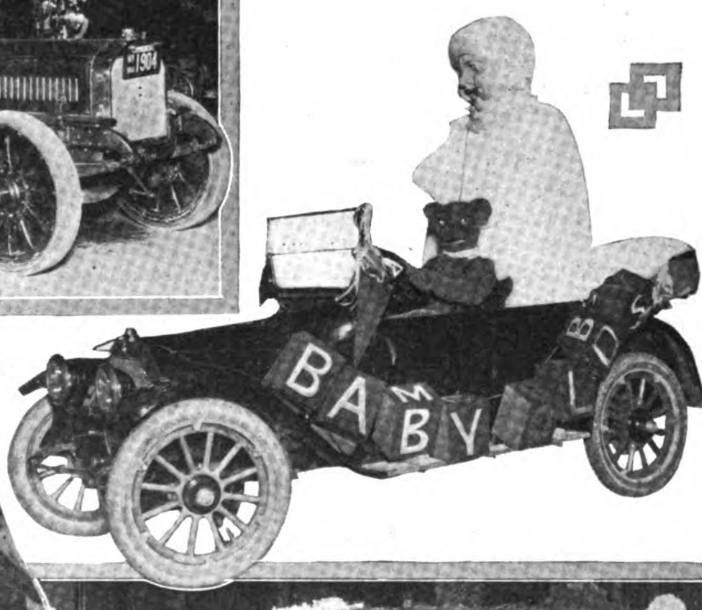
—

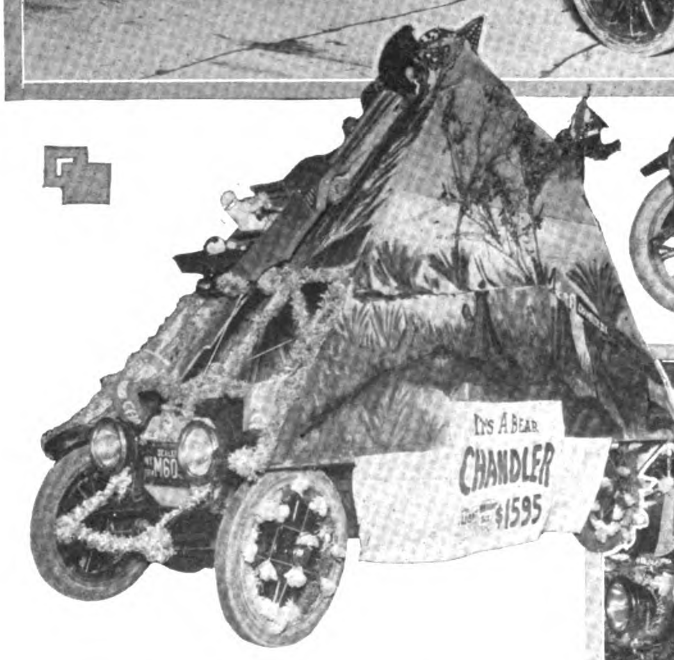
Fischer Car to Be Built in York

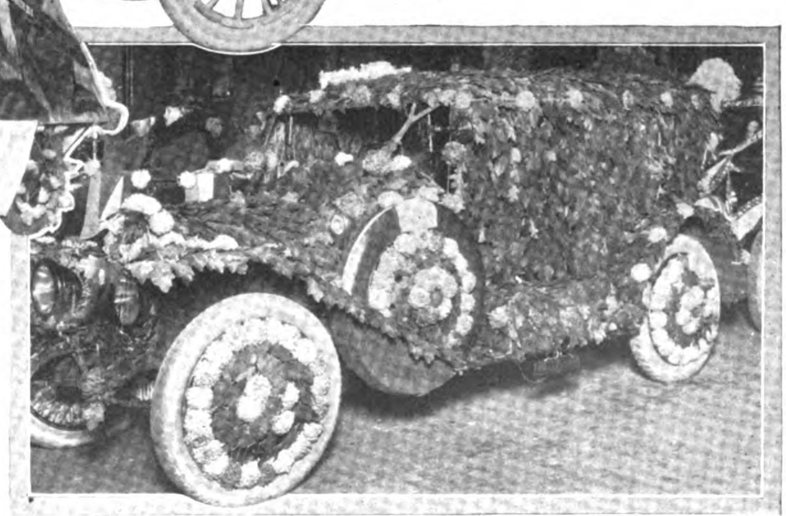
YORK, PA., Nov. 3—Announcement of a new automobile to be manufactured in York was made recently by C. J. Fischer, of Detroit, Mich. Yorkers have provided $50,000 capital to launch the concern. Operations will be started in the plant of the Glen Rock Stamping Co., located at Hill street and the Maryland & Pennsylvania railroad. The car will be an assembled one and the first will be turned out in 2 weeks, it is said. Sample cars are now in the city.

The corporation, which will be known as the Fischer Motor Vehicle Co., will, it is stated by Mr. Fischer, build five models on one standard chassis. There will be a two-passenger speedster at $595, a two-passenger cabriolet at $645, a two-passenger tourist at $595, a four-passenger Sedan at $845 and a four-passenger tourist at $645. The designs are by Mr. Fischer himself.

Left—Float of the B. F. Goodrich Co. in the Tercentenary pageant. Below—Baby Oldsmobile, which was awarded special mention in the Grotesque division







Above—One of the Chandlers. Brady-Murray Motors Corp., Chandler dealers, were awarded third prize of $75 for having most cars in a division. Right—Autumn float of Allen Auto Specialty Co., which took $100 third prize for best decorated car

Thinks Driving Through Springs Impairs Their Efficiency

The Automobile Engineers' Forum

Endurance of Springs Is a Function of the Stresses Imposed on Them—Effect on the Rear Axle Design

DETROIT, MICH.—Editor THE AUTOMOBILE:—Your notes on this question in THE AUTOMOBILE for July 23 and July 30 have been of interest, and a few additional points might profitably be added.

Referring first of all to the question to taking the driving, torque and braking stresses through the springs. This certainly reduces the production costs by reason of the elimination of torsion tubes and radius rods. The question as to which is the better method is worth discussion, however.

Might Impair Spring Action

General opinion would seem to suggest that the method of transmitting these additional forces through the springs is likely to impair their abilities to perform their functions as vibration dampers.

Primarily the springs need to have a predetermined flexibility, to give easy riding.

The endurance of the springs is a function of the stresses imposed upon them and, assuming equal physical properties of the spring steel, will the imposition of these additional stresses materially decrease their life?

An Explanation Needed

In view of the extremely satisfactory results attained from their use in this direction in instances of extreme severity, to instance the London omnibuses so equipped, and the fact of their being used on nearly all racing cars, some explanation should be forthcoming.

To consider the action of the forces imposed by the drive and torque.

The tendency of the springs when subjected to these loads is to assume a shape as shown in Fig. 1 where it will be seen that a point of inflection occurs at a point h in this extreme position.

Now let p = drawing effect concentrated at the anchored end, that is assuming the front end of the spring is fixed, thereby placing the spring under compression, and T the driving torque which is equal and opposite in magnitude and direction the axle torque. W = vertical load on the spring. The effect of the torque will be to increase this weight W by the amount I ÷ L.

The spring will normally have a certain camber H; the thrust P will therefore have a movement about the spring center equal to PH.

The effect of this movement PH will be to oppose the effect of the torque to create a point of inflection h which is the critical point and a condition which must be avoided.

This extreme condition is likely to take effect if when a violent bump occurs, the spring assumes a negative camber, as it will be observed that the moment PH due to driving thrust would increase the tendency to contrary flexure.

Reasonable Camber Desirable

Therefore the spring should have a reasonable camber under load.

This is contrary to general practice because it is well known that a flat spring under load will ride much better than one of excessive camber. This follows by reason that with a flat spring the momentary increase in load will act perpendicularly to the spring eliminating any horizontal component which would be delivered in the form of an impact from wheel to chassis.

Again, since the spring acts as a strut under the action of the driving effort, its resistance would obviously be greater if the direction of the force was directly along the neutral axis of the section.

Thin Leaves for Flexibility

It is generally supposed that the top leaf of the spring should be made of greater section to resist this additional force, but this would destroy the feature of thin leaves which are alone conducive to good flexibility, minimum stress, and hence long life.

In what manner will transmitting the drive and torque through the springs affect the design of the axle?

Effect on Axle Design

In the first place, the springs need to be rigidly connected to the axle case. The case will need to be made substantially stronger to transmit the torque, as on account of the length or distance of the twisting couple, that is from the center of the drive to the attachment of the spring, the angle through which the axle case would twist would be proportional to L and is a measure of the resulting stress.

Prefers Full Floating Axle

Therefore it would seem that a full floating axle would be preferable as the axle case would be sufficiently strong, while even were the semi-floating type to be considered for divergent reasons, its axle case would have to be materially strengthened, bringing its total weight approaching that of the full floating type while it would not possess the advantages of the former.

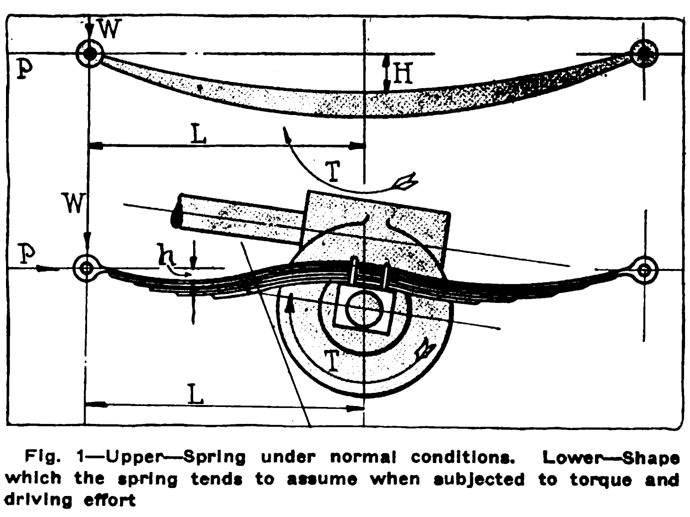


Fig. 1—Upper—Spring under normal conditions. Lower—Shape which the spring tends to assume when subjected to torque and driving effort

Again, a point worth noticing in the rigidly connected axle and casing, is the stresses induced in the axle casing by the oscillation of the wheels.

Assume one wheel to rise relative to the other. Normally the distance between the spring centers is L, Fig. 2.

When one wheel rises it should follow the arc of radius R with the center of the corresponding wheel as pivot, but since the point A is constrained to move in a vertical direction by the spring the axle must lengthen by an amount X equal to the difference between the length of L_1 and L.

A Fracture of the Axle

If, as is usual, the springs are stronger in their resistance to transverse twisting, fracture of the axle will eventually occur.

The alternative is the excessive binding action on the shackle pins causing excessive wear.

Instances of fractures of this kind are proved conclusively by the fact that the fracture occurred on the compression side of the axle, namely, on the top.

Eliminating Twist on the Axle Case

Where a separate torsion tube or radius bar is fitted a lighter axle will result, because the torque will be resisted by the tube at the center of the axle, eliminating the twisting effect throughout the axle case.

Instances where a cast-aluminum axle tube and casing were used joined in a vertical plane at the axle center, showed that, while the axle as a whole was strong enough to resist bending it would not stand up to the torque stresses and a steel liner had to be put along the whole length on the inside, with provision for transmitting the torque from the axle center to the point of attachment of the springs and hence to the frame.

Where a separate torsion member is fitted the best results of springing will be obtained when both ends are free, which means that the torque members and radius rod will need to such as to keep the axle in its correct relative position to the chassis.

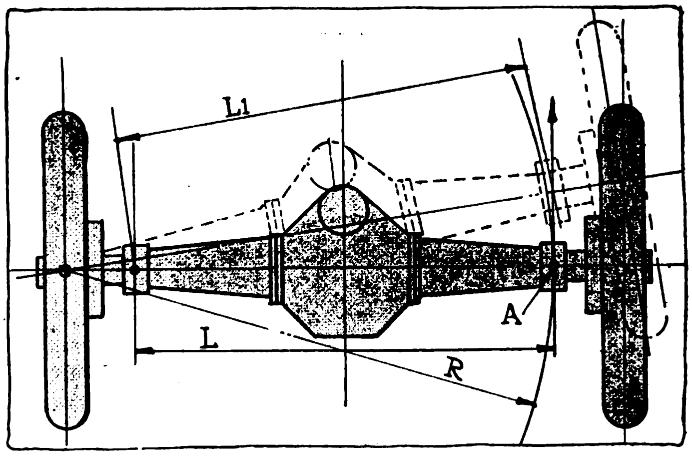

Fig. 2—Diagram illustrating the movement of the axle when one wheel passes over a bump

Single Torsion Member Inadequate

A single torsion tube or member would not suffice. Either two radius rods, one on each side or a triangulated member would have to be used.

Freedom of springing is obviously impaired when the springs are anchored at the forward end to serve as radius members, and a torsion tube is used in addition, as the axle when oscillating is restricted in its line of movement; following an arc of radius equal to the length of the torsion tube, but the path through which it would travel were there no torsion member would be an arc of radius equal to the distance from the spring center and anchored end, which will vary as the deflection. Hence unless these two paths can be made to coincide the springing is impaired.—A. A. Bull.

A Recent Court Decision—Husband Held Responsible

NEW YORK Appellate Division in an extreme case decides that a husband must stand responsible for injuries to a person struck by his automobile while his wife is using the car and chauffeur.

A physician who resided in Albany and owned a car ordered his chauffeur to drive him to a country club. On arriving there he directed the chauffeur to call for him at about 6 o'clock that evening. Late the same afternoon the physician's wife decided that she would drive to the country club and meet her husband there. There had been no arrangement of any kind made as to their meeting at the club and her decision was just made on the spur of the moment. Accordingly, she telephoned to the chauffeur and told him to bring the automobile around for her. He did this and, while she was on the way to the country club the chauffeur discovered an injured woman by the roadside and directed her attention to the injured woman. The doctor's wife ordered the car stopped and, finding that the woman was too badly injured to be moved, she told the chauffeur to go and get some nearby doctor. He did this and, while the doctor was coming back to the injured woman the chauffeur collided with a wagon and the doctor was injured. He thereupon sued the other physician, who was the woman's husband.

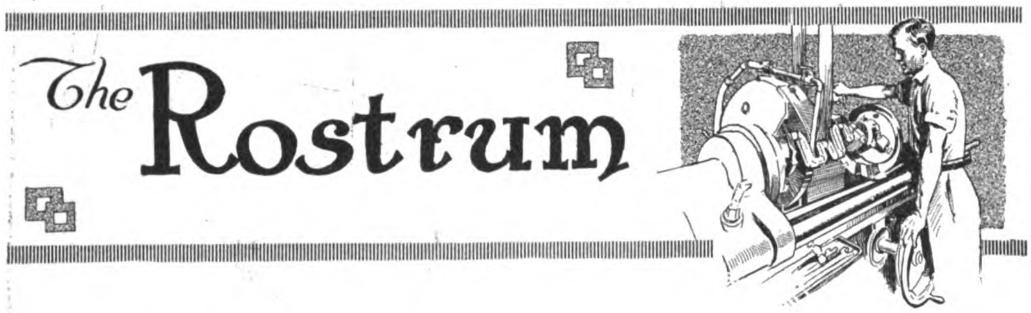
The Court held that, under the circumstances, the wife was not exercising exclusive control over the chauffeur but, having had authority to direct him to go for a doctor, her orders to him to do so did not destroy the relation of master and servant otherwise existing between the chauffeur and her husband. The Court therefore held that the husband was liable for the chauffeur's negligence which caused injuries to the doctor, after the jury decided that the chauffeur was the servant of the husband and not of the wife at the time of the accident. All the judges, except one, agreed on this decision; the one who disagreed claiming that, as there was no proof that the husband had hired an incompetent or careless chauffeur, or had a defective car, or even that he had any knowledge that his wife was assisting an injured woman, he was not liable for damages, stating that it would be carrying the rule too far to hold him liable in a case of this kind.

This case rather muddles up things in New York State as regards a man's responsibility for injuries caused by someone employed by him when that person is under the direction and control of a third party. Up to this time the New York courts uniformly held that, in order to render a car owner liable, it was necessary to show that the chauffeur was either acting under the owner's control or was engaged in the owner's business at the time of the accident.

It is to be hoped that the physician in this case will appeal to the Court of Appeals, in which event it would seem likely that the case would be reversed, in view of previous cases on this point decided by this court.—*McHarg vs. Adt*, 149 *N. Y. S.*, 244.

Ford Ships 21,976 Cars in September

Detroit, Mich., Oct. 28—During September, 1914 the Ford Motor Co., sold and shipped 21,976 cars, or an average of 733 daily. Compared with September, 1913, this year shows an increase of 11,479 cars, while in comparison with last August the increase is 1,338 cars. During the first 2 months of its new fiscal year beginning in August the Ford company has thus shipped 42,614 cars.



Where Power Is Lost in Automobiles

EDITOR THE AUTOMOBILE:—1—What is the percentage of efficiency of the average modern automobile?

2—What per cent. of the power developed by the engine is delivered at the rear wheels?

3—Explain where the efficiency is lost?

Lebanon, N. Y. CYRIL C. LAWTON.

—1—The efficiency varies greatly with conditions. Assuming that you mean the overall efficiency and not that of the motor, this depends on the road resistance, the wind resistance, the temperature, the efficiency of the motor and driving mechanism. The overall efficiency is the percentage of energy utilized in propelling the car to that supplied in the form of fuel.

Assuming that the car under consideration is one which was tested recently and which averaged 22 miles per gallon when running at an average speed of 24 miles per hour, the weight of the car being 3,230 pounds and the bore and stroke 4.25 by 5.25, the efficiency can easily be calculated if we know the road resistance and wind resistance. Not knowing these, we will assume that the road resistance is 50 pounds per ton and that the wind resistance is calculated.

The total tractive force required is $\frac{3,230}{2,000} \times 50 = 80$ pounds approximately. This force moves through a distance of 22 miles.

According to the formula given by Strickland, the pressure due to wind resistance is represented by the formula,

$$P = .0025\ SV^2$$

where P = pressure in pounds, S = surface in square feet, and V = velocity in miles per hour. S can be taken as 12 square feet, and the velocity, as previously stated, is 24 miles per hour.

Therefore, $P = .0025 \times 12 \times 24^2 = 17.25$ pounds.

Thus the total force which must be overcome is $80 + 17.25$ or 97.25 pounds. The total work done in foot pounds in moving the full 22 miles is therefore, $97.25 \times 5,280 \times 22 = 11,300,000$ foot pounds. Since 1 B.t.u. equals 778 foot pounds, this quantity is equivalent to $\frac{11,300,000}{778} = 14,600$ B.t.u. The heat in a gallon of gasoline expressed in B.t.u. is about 130,000 and therefore the efficiency is $\frac{14,600}{130,000} = 11.2$ per cent.

2—The average loss in the gearset on direct drive may be taken as 3 per cent. and the loss at the bevel pinions as 5 per cent. Allowing 1 per cent. for all the other losses the total will be 9 per cent. Therefore in this particular case, 91 per cent. of the power developed by the motor would be delivered to the rear wheels. In other cases the power transmitted might be higher and in others might fall as low as 80 per cent. This is assuming that the car is in high, on second the loss in the gearset may be taken as 6 per cent. This would increase the above estimate by 3 per cent.

3—You do not state whether you mean in the whole machine or just from the motor to the rear wheels. About 70 per cent. of the power is lost to the cooling water and discharged through the exhaust, then there is the friction in the bearings of the motor and the power required to operate the motor auxiliaries, such as the pump, generator, magneto, etc. There is a slight loss in the coupling between the clutch and gearset, and some power is wasted in the gearset, as already noted. A small amount of energy is absorbed by the universals, and the rear axle also requires energy, as previously stated. The rest of the power is absorbed in road friction, and in wind resistance. According to our calculations in answer to your first question, the distribution of energy may be tabulated as follows, the mechanical losses in the motor being calculated by subtracting all the rest from 100.

Lost to cooling water and exhaust heat..	.70
Mechanical losses in motor............	.10
Gearset losses	.03
Universals	.01
Bevel rear axle	.05
Road and wind resistance..............	.11
	1.00

How to Attach Electrical Meters to Hupp

Editor THE AUTOMOBILE:—1—I have a 1914 Hupmobile with Westinghouse starter and ignition system. Would you kindly explain how a voltmeter and ammeter could best be wired from the dash to the generator. A diagram would be much appreciated.

2—Will you also give me the names and addresses of reliable companies who manufacture ammeters and voltmeters?

3—Can an aluminum transmission case which is cracked, be welded or soldered strongly enough to withstand the continuous strain and jar? I have found that common solder will not adhere to aluminum; how is this accounted for?

Woodstock, Vt. E. H. REED.

—1—The wiring is extremely simple. The ammeter is connected as shown in Fig. 1, it being directly in the path of the current it is to measure. The voltmeter, on the other hand is attached across the two terminals of the generator, because it measures the pressure.

2—Following are a few names taken from the Automobile Trade Directory: General Electric Co., Schenectady, N. Y.; Hoyt Electrical Instrument Works, Penacook, N. H.; Keystone Electrical Instrument Co., Ninth street, and Montgomery avenue, Philadelphia, Pa.; Wagner Electric Mfg. Co., 6400 Plymouth avenue, St. Louis, Mo.; Weston Electrical Instrument Co., Newark, N. J.; Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.

3—An aluminum solder was described in the Sept. 17 issue of THE AUTOMOBILE, page 564. According to the maker, this solder is stronger than the aluminum, and the aluminum will break before the solder will. If the crankcase is welded, it should also be strong enough to withstand the strain.

Edison Storage Battery Lighter

Editor THE AUTOMOBILE:—1—What is the difference between an ordinary storage and an Edison battery?

2—What does each weigh, such a size as is used on a 3-ton truck, and what is the cost of each?

3—Can such a battery be charged while current is being drawn from it? If so, how long will it take and what equipment is necessary to do it.

4—Is there very much difference between these batteries and a battery used for cranking and lighting?

5—Will you publish a list of addresses of manufacturers of garage tools supplies and steel working machinery?

6—What is the address of the Stanley Steam car?

7—What are the objections to a two-cycle motor?

8—Where can an instruction book for Elmore cars be obtained?

9—Why was the manufacture of these cars discontinued?

10—Can gas such as generated from carbide be used in an automobile engine?

11—How many cubic feet of gas and vapor will a pound of carbide produce?

Cooper, N. C. A READER.

—1—The ordinary lead storage battery uses lead plates immersed in an electrolyte of sulphuric acid of a specific gravity of about 1.280, when the battery is charged. The positive plate consists of lead peroxide and the negative plate is sponge lead. Pure lead is used to form the framework of the plates or grids, which carries these two substances, lead and lead peroxide. These grids also carry the current out to the battery terminals.

Edison Uses Potash Solution

The Edison cell on the other hand uses a 21 per cent. solution of potash in distilled water. The positive plate consists of one or more perforated steel tubes heavily nickel-plated, filled with alternate layers of nickel hydroxide and pure metallic nickel in excessively thin flakes. The tube is drawn from a perforated ribbon of steel, nickel-plated and has a spiral lapped seam. This tube, after being filled with active material is reinforced with eight steel bands, equi-distant, which prevent the tube expanding away from and breaking contact with its contents.

The negative plate consists of a grid of cold rolled steel, nickel-plated, holding a number of rectangular pockets filled with powdered iron oxide. These pockets are made up of very finely perforated steel, nickel-plated. After the pockets are filled they are inserted in the grid and subjected to great pressure between dies which corrugate the surface of the pockets and force them into practically integral contact with the grid.

These plates are housed in a jar or container made from cold rolled steel. The container is welded at the seams, the walls are corrugated for strength and the steel is nickel-plated.

Hard to Make Fair Comparison

2—It is difficult to compare these batteries, because the capacities used in various trucks will vary with the make of truck, etc. The only fair way would be to determine how much each type of battery would weigh and cost, to give the same performance in the same truck.

To give you an idea, however, a lead battery for an ordinary 3-ton truck might weigh 2,500 pounds and cost about $500. Such a battery would have an ampere hour capacity of 260 and would give 110 volts, 44 cells being used.

Another truck, of 3.5-ton capacity, however, is equipped with an Edison battery weighing 2,250 pounds, and costing $1,980. This battery has an ampere hour capacity of 375 rated and 475 actual under ordinary conditions of operation. The voltage is 72.

Therefore it is seen that the conditions are so different that little comparison can be made.

3—This is an obvious impossibility and there is no place where it is required. If you attempted to draw current from a battery on charge you would draw from the charging circuit and not from the battery.

4—The only material difference between the different types is that the starting and lighting battery is made of just the right capacity for the work it has to do and therefore it is of much smaller size.

5—This is entirely too long as there are many hundred names on the list. We advise you to write the Automobile Trade Directory, 239 West 39th street, New York City.

6—Stanley Motor Carriage Co., Newton, Mass.

7—The objections to the two-cycle motor are that it is difficult to throttle down, it is uneconomical, and is not as adaptable to high speeds as the four-cycle.

8—Possibly the Auto Parts Co., Chicago, Ill. or the Elmore Auto Repair Co., 247 West 47th street can supply you. These two concerns handle parts for this car and may be able to furnish you with an instruction book.

9—The manufacture was discontinued because the company failed.

10—Yes. Occasionally we hear of a motorist driving home on acetylene gas when his supply of gasoline is exhausted. The objection to the use of this gas is that it is much more expensive than gasoline.

11—One pound of carbide will produce .407 pounds of acetylene and this corresponds to 6.3 cubic feet at 70 degrees Fahrenheit.

Motor Overheats Badly: Water Boils Away

Editor THE AUTOMOBILE:—I have a model 14 Buick runabout. It has a two-cylinder, opposed motor. To date the car has not been run to exceed 1,000 or 1,200 miles. The trouble is it heats the water excessively, using about 1 gallon to every 7 or 8 miles. Have had it overhauled by several and they pronounce it to be in good working order; has good power and it performs satisfactorily, only uses too much water. It has a thermo-syphon system of cooling.

Recently I had a pump installed, but this does not lessen the consumption and heating of water. Have had new 1 1-4-inch hose put in the circulating system and thoroughly traced water course for any stoppage, but none to be found. Seems to boil the water in the jackets like when water is poured on a hot stove. The original radiator was somewhat battered on the inside by the fan wheel getting loose, and I had the radiator reconstructed so as to hold about a gallon more water. It heats as much now as with the original one. So I do not think it is in the radiator as it got just as steaming hot before I had any change made. I have had the timing changed, which has helped the speed and power at least 25 per cent. I use plenty of lubrication but this does not seem to help any.

The maker claims it is all in the radiator, but I do not think so, as the original one heated the same. Would like

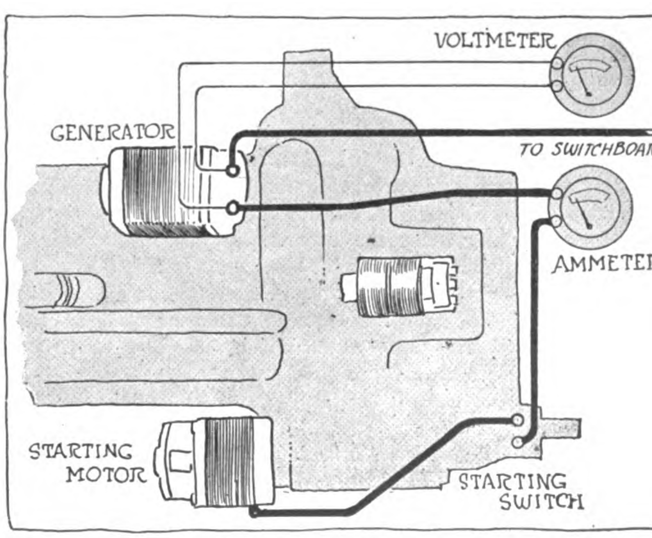


Fig. 1—Diagram showing wiring connections for attaching ammeter and voltmeter to 1914 Hupmobile

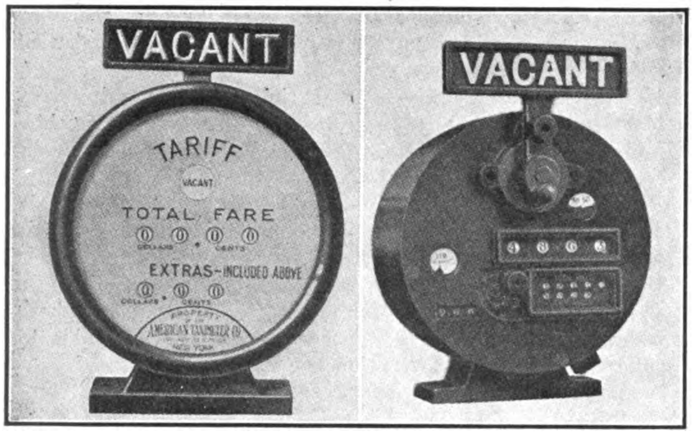

Fig. 2—Front and rear views of a taximeter

to hear from any one who can suggest a remedy for this trouble. Have tried a dozen or more suggestions but with no results. What does THE AUTOMOBILE think is the cause? There is no stoppage in the water circulation; carbureter works well and no misfiring; everything else is all right.

Syracuse, N. Y. A. W. SMITH.

—The Buick model 14 uses a vertical tube radiator, in which the water runs simultaneously through all tubes. If your radiator ever worked properly a repair such as you speak of could not increase its capacity by a gallon. It may be, however, that, prior to the accident a part of the radiator, a tube or two, was closed, and when the radiator was repaired, was opened up. The water capacity of this cooling system is 2 1-2 gallons, and if it does not hold this much, something is radically wrong. It may be possible that while your system is up to normal capacity, the water does not circulate properly, due to an obstruction in the line, perhaps in the cylinder passages. Continued use of hard water may have deposited a scale in the interior of the radiator that prevents proper radiation. To determine which of these is the case, or if none of them, what the real difficulty is, proceed as follows, always remembering that it is not a fault in design but the result of an abnormal condition.

First Drain Radiator

First drain out your radiator and cooling system, refilling it with clean water. Measure the amount that you put in, and if it is not as much as 2 1-2 gallons, you may know that your system is not of normal capacity, due either to stoppages in repairing the radiator, or core sand, or deposit from dirty or alkali water. When the radiator is full start your motor, and let it run until the water is hot, then feel all of the tubes in the radiator. If any of them are cool, they are not circulating, and are probably clogged or closed through an error in manufacture or repair. Next, to test the circulation, disconnect the outlet hose, and with the motor running, put fresh water into the radiator to take the place of the water running from the disconnected exhaust. Drop some aniline color or ink into the radiator, watching the outlet to determine how long it will take it to run through the system. If it comes through greatly diluted, and continues to come long after the last is put into the radiator, there is an obstruction in the passages which allows the water to pass only very slowly, and may be due to caked core sand and scale, or vegetable matter or sand in the water, introduced into the circulation by careless straining of the water. It is barely possible that a lump of iron was left by the core in casting which escaped the notice of the inspectors.

If, after all of these tests, it is found that the cooling system accommodates its full capacity of fluid, that it reaches every surface of the radiator, and that the circulation is rapid and thorough, your over heating must be due to errors in driving, to wit, running on retarded spark, in low gear, or with an over-rich mixture, or to a deposit of scale on the interior of the radiating surfaces which prevents proper radiation. If the former, the remedy is obvious, if the latter, the system should be cleaned with one of the numerous radiator cleaning compounds.

If it is found that the water is not circulating through all of the radiator tubes, the radiator should be thoroughly cleaned and overhauled, and the ends of the tubes inspected if possible. If there are obstructions in the cylinder passages, their nature should first be learned, and if possible immediately removed. If it is found to be a flaw in the casting, it may be necessary to replace the cylinder, if no way can be found of reaching it from the outside.

How a Taximeter Works

Editor THE AUTOMOBILE:—1—Will you please give me the addresses of several manufacturers of taximeters? 2—What sort of a record does a taximeter keep? Does it show anything besides the amount of money taken in? How does the clock attachment work?

I am contemplating starting a taxicab line, but know but little about the working of the meters.

McCook, Neb. ROBERT L. FERGUSON.

—1—According to the Automobile Trade Directory, taximeters are made by the following concerns: American Taximeter Co., 735 Seventh avenue, New York City; International Taximeter Co. of America, 239 West 68 street, New York City, and the Pittsburgh Taximeter Co., Center and Negley avenues, Pittsburgh, Pa.

2—There are two principal types, the one-tariff meter which registers at but one rate, and the two-tariff meter which will permit of charging at one rate for one or two passengers, and at a higher rate for three or more. Provision is made for additional charge for baggage, etc., under extras. This record is rung up by the driver and shown separately on the dial.

In some meters the extras are automatically added to the total fare, while in others the totalizing feature is omitted, the extras being computed separately.

When the cab is disengaged, the flag on the meter is upright, displaying the vacant sign. Upon a passenger being taken, the flag is turned to the right 90 degrees, or one-quarter of a circle, and the figures Tariff One and the initial fare appear upon the dial. In this particular case for instance, the initial charge is 50 cents. This will carry the passenger the first half-mile, at the end of which the meter will record an additional charge of 10 cents for every quarter-mile thereafter, and 10 cents each 4-minute period of waiting time. Any other rates of fare may be had.

Where it is desired to use Tariff Two—for a larger number of passengers—the flag is turned around three-quarters of a circle, to a position opposite to that of Tariff One. This will cause the figures Tariff Two and the initial charge of 50 cents to appear. The initial charge will in this case cover the first one-third mile, registering 10 cents additional for every one-sixth mile thereafter. Waiting time is recorded as the same time as Tariff One—10 cents for each period.

At the termination of a trip the flag is turned to the lowest point of its travel. This is the Not-Recording position. The dial reading Total Fare, and Extras is unchanged, but the words Not-Recording appear instead of Tariff One or Two. The clock is disconnected from the Total Fare reading, preventing the automatic addition of money for waiting time while the passenger is in the act of paying his fare.

The Non-Recording position is also used in the event of mishap to the cab, necessitating repair or the procuring of a substitute cab, in which case the passenger is not responsible for the loss of time, and would naturally object to paying for it.

Should the driver attempt to operate with passengers, the flag being in the Not-Recording position, additional fare and mileage will continue to record. Upon the fare being paid, the flag is again moved to the Vacant position, the dial is returned to zero, and the meter records only the total mileage when the cab travels, until another passenger is taken and the flag again operated.

The Owner's Record

The rear face of the taximeter contains the owner's record. It is permanent and is not returned to zero by the movement of the flag after each trip, but continues to register all additional fares, mileage, etc.

The circular dial in the upper right side shows the number of trips, or times the flag has been operated from Vacant to Vacant. Below this is the permanent cash record, or total amount of the fares, including Extras received. This is read backward. For instance, the figures 4863 would mean $368.40.

Mileage is registered in miles and tenths in two lines of numerals in the lower right side. The top line records total mileage. The lower line total paid, or live mileage. Unpaid mileage can be easily found by subtracting the lower amount from the upper.

The small circular dial on the left registers the time in 1-minute periods that the flag is in the Not-Recording position.

Recording of Extras

Extras are recorded in the oblong space on the lower left side. They are also included in the cash record. The separate recording of this item will prevent any abuse of the Extras feature on the part of the driver.

The flag may be locked in any of its positions, preventing tampering by malicious persons in the possible absence of the driver. The locking, registration of Extras, and winding of the clock, are accomplished by means of a key furnished for these purposes.

Advantages of Friction Drive

Editor THE AUTOMOBILE:—Has there ever been published in THE AUTOMOBILE an article on the advantages and disadvantages of the disk-friction-chain drive compared with other types of transmission now more commonly used? If so, would you kindly give me the reference? If not, will you please give me your views on the subject?

Ithaca, N. Y. FRANK E. RICE.

—Nothing has been published on this subject in the past few months. The advantages of the friction transmission are that it offers an infinite number of gear ratios, is silent, cheap to manufacture and simple. The disadvantages are that the friction disk must be renewed every few thousand miles; this is a small matter, but worth noting; and that the amount of horsepower that it will transmit under the conditions found in automobile design is limited. Therefore it has never been used to any extent on large cars but has found favor on some cars of medium size and on more small cars.

Not Advisable to Change Gear Ratio

Editor THE AUTOMOBILE:—I am the owner of a 3,000-pound car, having a bore of 4 1-8 inches and stroke 4 1-2 inches with tires 34 by 4 and a gear ratio of 3 3-4 to 1, and am desirous of changing it to a 4 to 1 gear ratio. Would you please explain the difference between the two ratios relative to this car in regard to vibration, heating and wearing of engine parts, gasoline mileage, hum in differential and other advantages or disadvantages between the two ratios?

This car shows no vibration at 30 miles at present ratio. Am in the habit of running 15 miles per hour.

Waltham, Mass. C. A. DUBOIS.

—There will be little difference in these two ratios, the lower one will require that the motor run 1.066 times as fast, and this will increase the noise, vibration, heating, wearing, and gasoline consumption just that much.

This difference is not worth the change as it will cost a considerable amount to put in the new gear ratio. A new pinion and gear will be required and if these cannot be obtained from stock it will be necessary to make them up specially at additional expense.

If your car is in good condition, there is no reason why you should discard the gear ratio you now have because the motor should be powerful enough to make the car a good hill-climber. However, if you desire a lower gear it would be better to install a 4.5 to 1 ratio, as this will make a noticeable difference.

Bent Knuckle Hard to Repair

Editor THE AUTOMOBILE:—1—Please advise me regarding an argument which we had in our shop lately.

We had a steering knuckle on a Buick car which required straightening. I argued that it could be done either cold or by heating and that heating would do no harm, but on the other hand would lessen the danger of crystallization.

Other parties argued that heating would allow it to bend easier in the future and that no good machinist would do it any way but cold.

Titonka, Ia. VICTOR LAMOREUX.

—If the knuckle is straightened at all it should be done hot. It is better to put in a new one, however, as it is difficult to straighten it so that the wheels will run true. If the bend is in the spindle there is no possibility of straightening it satisfactorily and even if only the arm is bent it will be hard to true it up.

Buy New Set of Ford Magnets

Editor THE AUTOMOBILE:—I am under the impression that I saw a letter in THE AUTOMOBILE explaining a method of charging Ford magneto magnets without taking them out. If you have published such a letter, I would be pleased to have a copy containing it.

Fairchance, Pa. CARL LIGHTFOOT.

—We have never described such a device. Recharging these magnets is hardly worth the trouble because a new set may be purchased complete and ready to install for a total expenditure of about $4.

Will Water Remove Carbon?

Editor THE AUTOMOBILE:—I note in THE AUTOMOBILE that someone advocates dropping water in the carbureter when the engine is hot and running to remove carbon. I heard of this several years ago but dared not try it until recently. I thought it worked well. What do you think?

Portland, Me. GEO. W. CHASE.

—We have had no experience with this method of removing carbon. Possibly some of our readers have tried water and will give their experience.

Control of Materials and Dimensions in German Manufacture of Steel Balls and Ball Bearings

A SUBJECT BEARING UPON AMERICAN INDEPENDENCE OF IMPORTATIONS

THE means adopted by the Deutsche Waffen- und Munitionsfabrikken in Berlin to secure uniform qualities of the materials used for balls and ball bearings and uniform accuracy in the dimensions of these products are described by W. Bockermann.

From 1898 to 1909 the D. W. F. concern conducted its scientific investigations of problems arising in the manufacture of steel balls and bearings in connection with the Zentralstelle für Wissenschaftlich-technische Untersuchungen (Central Institution for Scientific-technical Investigations) at Neubabelsberg near Berlin. Its own testing department for materials was established in 1910 and was combined with the department for the mechanical testing of the products, which had already existed for about ten years and which was enlarged on the same occasion.

The mechanical laboratory, Fig. 1, comprises a Martens-Heyn hardness tester, a Brinell press for testing hardness, an Amsler-Laffon press of 60 tons capacity with an auxiliary cylinder of 6 tons pressure; also a press of 200 tons capacity. To the right in the illustration there is seen a machine for grinding and polishing of test pieces for metallographic examinations and in the background a device for the control of the accuracy of pyrometers. The microscopes are all made by Carl Zeiss of Jena and include a measuring-microscope for the hardness tests, a large metallurgical microscope and a binocular microscope [to give the perspective effect of the etched portions of polished test pieces—ED.]. A Martens mirror is at disposal for measuring deformations during testing operations.

Figs. 2 and 3 give an idea of the equipment of the chemical laboratory, showing respectively the titration room with the analyzing room behind it and the electrolytic plant with device for burning carbon electrically. Some of the mechanical testing devices for the finished product may be recognized in Fig. 4, while Fig. 5 shows the arrangement of the ball inspection department.

The chemical analysis of some of the steels used for balls and races is given in an appended table.

Percentage of	Balls up to .5 in. diam.	Balls above .5 in. diam.	Races.
Carbon	1.23	0.95	1.01
Manganese	0.31	0.29	0.26
Silicon	0.16	0.36	0.23
Phosphorus	0.017	0.028	0.020
Sulphur	0.015	0.028	0.020
Copper	0.012	0.01	0.008
Chromium	——	1.25	1.33

Material is received, according to its purpose, in the form of wire, rods, tubes, disks or blocks. Samples are taken from every lot and are examined with regard to chemical composition, texture, natural hardness and hardness as well as toughness after hardening by heat treatment. There is demanded a material free from cracks and pores and showing a microstructure of fine-grained perlite. The best test for hardness has been found in the Brinell method of measuring the indentation made by pressing a steel ball into the material. But this test is not made with a ball of 10 millimeters diameter and a pressure from 2,000 to 3,000 kilograms, as is usual, but with a 5-millimeter ball and 500 kilograms pressure. Under the higher loads the hardened material frequently developed superficial cracks, and these may be very detrimental for the durability of a ball bearing. This does not occur with the smaller ball and the 500-kilogram load. The conditions for obtaining reliable results by this method comprise: a press working perfectly, balls of uniform hardness, a good polish of the surface where the indentation is made, a delicate film of lampblacking, correct

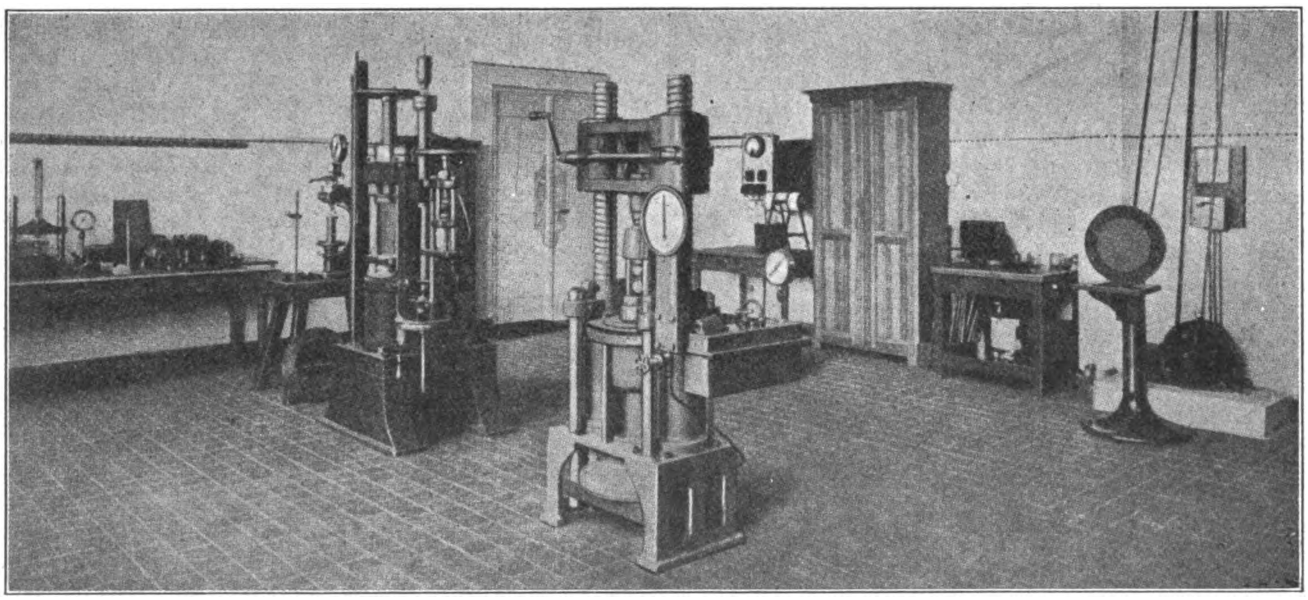

Fig. 1—Mechanical laboratory with presses for testing raw materials for hardness and toughness; also micrographer equipment

adjustment of the microscope (so that the planes of the image and of the crossing threads coincide accurately), a suitable illumination and, finally, practice on the part of the workers. The balls used for the press are made specially for this purpose and of unusual hardness, which is the property that is most essential, but their toughness is thereby somewhat reduced and the number of wasters is increased.

The determination of the toughness of the hardened steel gains additional importance from the fact that the results indicate how well the material has been handled at the rolling mill. This property is measured by bending tests, and these are also directly useful, as the chief stresses to which a ball bearing is subject are pressure and bending stresses.

The examination of the materials is continued during the processes of manufacture. Each bearing ring is measured and inspected for defects after each machine operation and each process of heat treatment. After the hardening the rings are tried searchingly for hardness and toughness. Each ring is tried for hardness in several places with a three-cornered file and thereafter it is dropped on a steel plate from a height of 2 meters. Those which are too brittle are broken by the fall.

The bearing balls are, as a rule, not inspected till finished. By the play of light and shadow when the balls are moved around on a glass plate, defects of material or workmanship become plainly visible, and balls seen to be defective are of course put aside by the young women doing this work, (Fig. 5.)

Rings and balls are often tried for hardness, toughness and strength. The toughness of rings is determined by compressing them radially between two flat plates. Hardness of balls is tested by pressing two balls of equal size against each other. In the case of large balls, which preferably should not be destroyed by the test, the load applied is $5D^2$ kilograms, where D stands for the ball diameter in one-eighths of an English inch, so that the load for a 2 1-2-inch ball, for example, becomes $5 \times 20^2 = 2{,}000$ kilograms. By this load no measurable permanent deformation arises. When the value of the test-object is of no importance the hardness is decided with loads from $50D^2$ to $300D^2$.

The toughness of the balls is also determined by pressing two of them against each other. They are placed in a guide block, one over the other, as in Fig. 6, and loaded to destruction. It is an interesting observation in connection with this test that, when a cone whose base equals the area of contact between the two balls is driven in between them, only one of the balls, as a rule, is destroyed at first. The other one bursts frequently at the moment the load is removed, into two even halves, but it also happens often that it does not

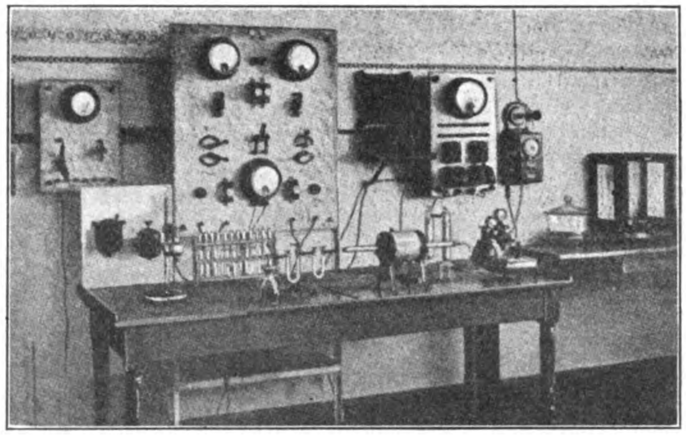

Fig. 3—Plant for electroplating and determination of carbon contents

burst till after a considerable length of time, which may be hours and even days, and then with a distinctly audible report. Fig. 7 shows a pair of balls destroyed in this manner, together with the shearing-cone.

The ultimate load for balls varies within rather wide limits, but this is not so objectionable as might appear at first thought, as it is the balls which for some reason—slight variations in the hardening temperature—have become least hard which show the greatest ultimate load. When this load is taken as a measure for toughness, the hardness should therefore at the same time be considered. A high ultimate load is only then a sign of satisfactory toughness when the hardness is also sufficient.

In the department for the testing of the steel materials the other substances which are used are also examined, such as bronzes, brass, oils, benzine, soaps and paper, and these examinations relate mainly to the properties required in these materials for their use in connection with ball bearings. [The author here refers to the ball cages, whose metal should not wear off on the balls and should hold their shape and their cross-pins, to lubricating oils, etc., which should be free from acidity, and to the avoidance of hygroscopic properties in the wrappings for ball bearings held in stock.—Ed.]

The Control of Dimensions

Aside from the accuracy required in the machine tools by which the parts of ball bearings are turned out, a large and varied collection of fine measuring tools is a necessary equipment, and in order to keep these fine tools constantly up to a high standard of accuracy a measuring department has been established.

A considerable wear of the measuring tools follows from

Fig. 2—Titration room with chemical analysis room adjoining

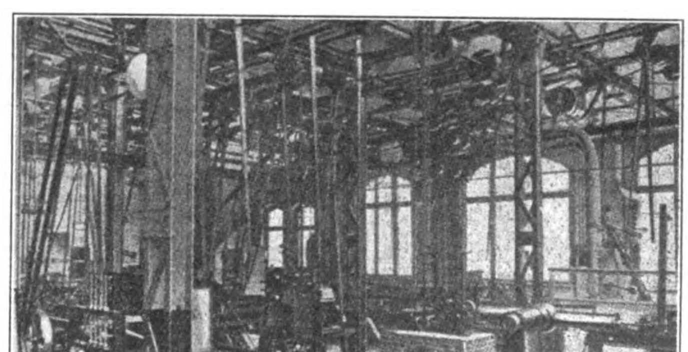

Fig. 4—Equipment for mechanical testing of finished bearing rings

the fact alone that the tolerances allowed in the manufacture are very small, so that much rubbing takes place. The tolerance for the bore of a bearing ring does not exceed 0.015 millimeter, and the same accuracy is required for external diameters up to 50 millimeters, increasing to 0.02 for rings of larger dimensions; for balls the variations must not exceed 0.002 millimeter. Naturally the manufacture is operated from beginning to end with tolerance calipers and rules, and these are produced and calibrated at the factory. The

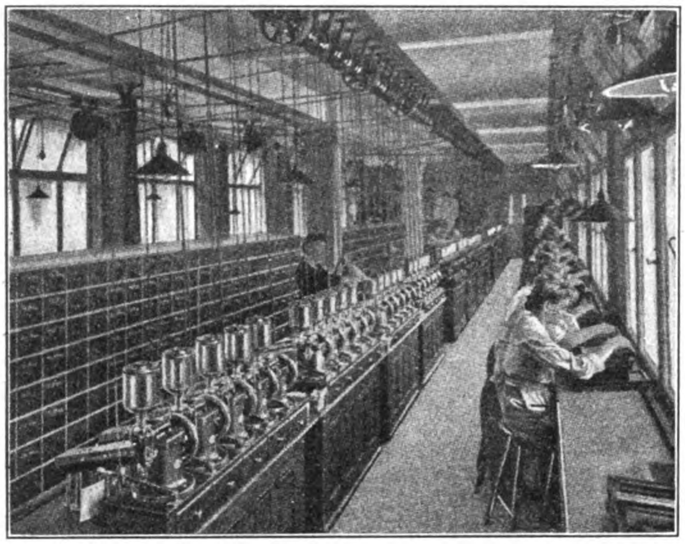

Fig. 5—Testing of steel balls by play of light

calibration is done in the measuring department by means of the following machines:

(1) A measuring machine from I. E. Reinecker of Chemnitz, with a range of about 300 millimeters. To this machine belongs a set of Reinicker measuring blocks in lengths from 5 to 100 millimeters. These blocks are tested by the Physikalisch-Technische Reichsanstalt with an accuracy of plus-minus 0.001 millimeter and are revised from time to time in the same place. Up to lengths of 50 millimeters an accuracy down to even 0.0005 is guaranteed. To go further seems unnecessary, as a difference in temperature of only 1 degree centigrade makes a differnce of more than 0.001 millimeter on a length of 100 millimeters.

(2) A Sauter & Messner measuring machine of the same range.

(3) A device for measuring thickness, from Carl Zeiss, with a range of 105 millimeters. The two other measuring-machines apply a pressure, when used, of respectively 4.2 and 5 kilograms on the work piece, and this pressure in some cases would interfere with accuracy. Thin rings, for example, are ovalized by it and balls are flattened at the measuring places. While these minute deformations lie within the elastic limit and have no permanent effect upon the actual dimensions of the work piece, it is a matter of experience that they result in the diameter of such pieces being regularly measured too small. With the Zeiss measure this drawback is avoided, as the pressure is only 0.09 kilogram.

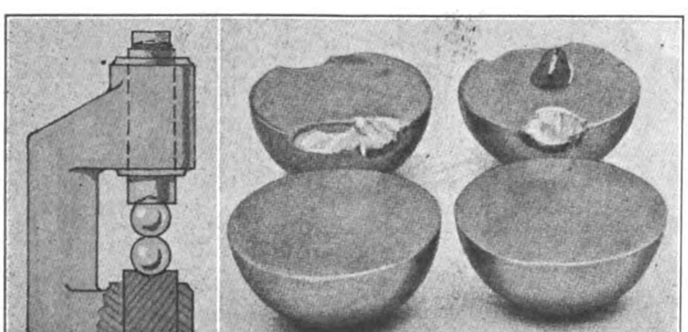

Fig. 6—Ball press for toughness test. Fig. 7—Test illustrating that two balls are never of equal strength

(4) A thickness and ovalization measure with minimeter from Hirth at Cannstatt. This device, like the measuring-machines, must be adjusted by means of the measuring-blocks, and the range for each adjustment is rather small and depends upon the individual minimeter that is used. With a multiplication of 1 : 500 the range is only 0.04 millimeter. The instrument is therefore mainly used for measuring tolerances.

(5) Two standard sets of Johannson measuring blocks, of which one is used constantly while the other serves for controlling the first one.

(6) An extension set of Johannson blocks in lengths from 150 to 300 millimeters.

The Reinecker measuring-machine is protected by a glass case against dust and changes of temperature, and the measuring-room where it is kept has northeast exposure, an outside wall 50 centimeters thick and double windows, so that the temperature can be kept almost constant.

For trying out complaints there is in the measuring-room a complete set of tolerance calipers from 5 to 100 millimeters of an accuracy of plus-minus 0.001 and adapted for measuring all of the tolerances guaranteed in the firm's catalogs. It is found advantageous to have complaints thus passed upon apart from the commercial offices.

The normal temperature is assumed to be 20 degrees centigrade; that is, all measuring-tools agree exactly with their nominal dimensions at this temperature. While in scientific institutions the normal temperature is taken as 0 degree, most large concerns have found it unpractical to adopt this standard, as it is very seldom that a piece of work can be measured at this temperature, while it is comparatively simple to keep the measuring room at 20 degrees, thereby avoiding calculations or reference to tables.—From *Zeitschrift des Vereines Deutscher Ingenieure*, August 15.

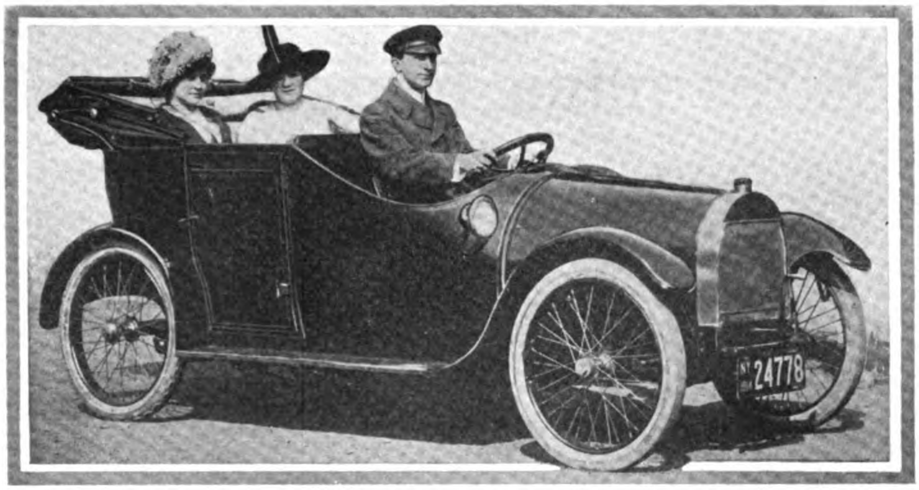
(*To be continued*)

Dividing Germany's Export Trade

IN discussing the best means for securing the export trade which Germany has established all over the world, and not least in France, England and Russia, the French and English technical and class journals furnish many interesting figures to show the volume of the trade involved. It is noticed that the total German exports in 1912 amounted to about 2,240 million dollars of which 38 per cent. went to the nations with which she is now at war. The machinery trade represented 170 million dollars and during the first six months of 1914 electric machinery alone brought Germany more than 35 million dollars. The steel export aggregated in 1912 more than 140 millions, coal the same amount, cotton fabrics 106 millions and leathers nearly 60 millions.

During the same year, however, the German importations amounted to about 2,700 million dollars, and when it is assumed that it should be possible to capture most of the German export during the war and to hold it afterwards, the purchasing capacity indicated in the German importations should also be considered; that is, means should also be discussed for taking from those countries which have traded with Germany an amount of goods similar to that which Germany had to buy from them in order to establish a practicable trade balance, without which the purchasing capacity ceases to exist.

The demands of the situation thus revert curiously to those existing two generations back, when shipowners or captains bought suitable cargoes for speculative export to some foreign port and were prepared to take suitable return cargoes for their home country or intermediate ports—the days when commercial adventure filled the place since taken by commercial organization and international banking facilities.



Two views of the new Twombly taxicab to sell for $600. The passengers have an unobstructed view because the driver sits in the center

Twombly Taxi $600

Maximum Rate 25 Cents Per Mile—Four Cylinders and Sliding Gears

TAXICAB transportation for two passengers at a cost of 25 cents per mile is the maximum rate allowed for the new cab manufactured by the Twombly Car Corp., Nutley, N. J. This cab, which was briefly described in the October 22 issue of THE AUTOMOBILE, is a well-finished landaulette design, painted maroon and upholstered in cloth. The low charge for passenger transportation is due to the fact that there is no excess weight, the car complete tips the scales at 1,400 pounds it is claimed and the initial cost is low, being $600. The motor is a four-cylinder water-cooled design. The wheelbase is 100 inches, the tread 44 and the tires measure 28 by 2.5 inches.

Realizing that if these cabs were sold outright without any restrictions many short-sighted owners would charge the same rate that present taxicab operators are charging, the Twombly company will not actually sell these cars but will give a perpetual lease which allows the owner of the lease all the privileges that a purchaser would have with the exception that if more than 25 cents per mile is charged the cab may be taken back. The operator of the cab may charge as much less than this rate as he sees fit.

This small, light-weight, two-passenger cab was designed, it is stated, after studying the taxicab situation in New York City, where it was found that 80 per cent. of the time not more than two passengers were carried.

Running Expenses Low

The actual running expenses of this cab are extremely low, and guaranteed to be not over 1 5-8 cents for gasoline, oil and tires. It should actually be much below this figure. Probably for the first time in history, it is claimed, a tire company has agreed to guarantee the tire cost to be not over 5-8 cents per mile and the Twombly company guarantees that the consumption of gasoline will not exceed 1 cent per mile.

It is expected that within a few months, a fleet of cabs will be operating in New York City, the charge for the first mile being 25 cents and 5 cents for every quarter mile thereafter. This is just half the present rate. These cabs are to be operated by an independent company. The Twombly company is confining its efforts entirely to manufacturing.

It is anticipated that with the increase in popularity of these low-rate cabs that there will be sufficient of them on the streets and sufficient demand for them, to eliminate the loss due to returning to the cab stand empty. At present, the taxicabs start from the stand, deliver their fares and return empty, the return trip is a dead loss. By reducing the rate, the demand will increase, and with it the number of vehicles with the result that near the spot where the fare is delivered a new fare will be picked up. In this way the cab will eventually work back to its stand, and pay its way while so doing.

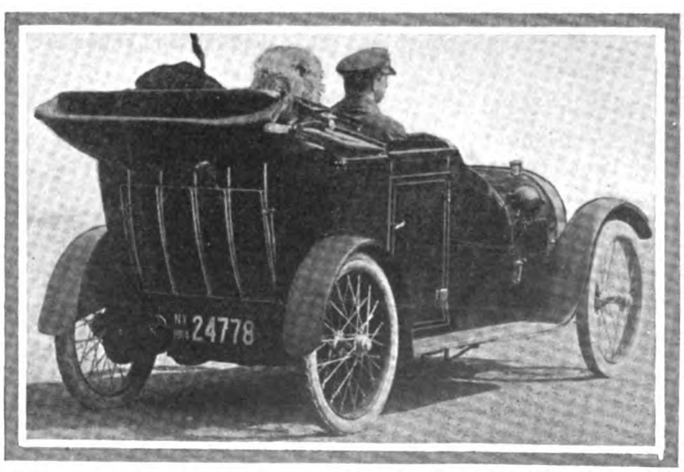
L-Head Block Motor

The motor is an L-head, block design, 2.75 by 4 inches. Cooling is by the thermo-syphon system, a honeycomb radiator being used. Lubrication is by a combination splash and force-feed system.

The rear axle is fitted with New Departure bearings and the differential action is obtained by the use of roller clutches. The front axle is a drop-forged, I-beam type with annular ball bearings in the wheel spindles. There are two brakes on each rear wheel, the service being external and the emergency internal.

The steering gear is an adjustable design which the driver can swing out of his way when getting in or out. A 14-inch wheel is used and the gear itself is an irreversible worm and sector type. There is a hand throttle on the dash and a foot accelerator. The service brake is pedal-operated, and the other is actuated by a lever.

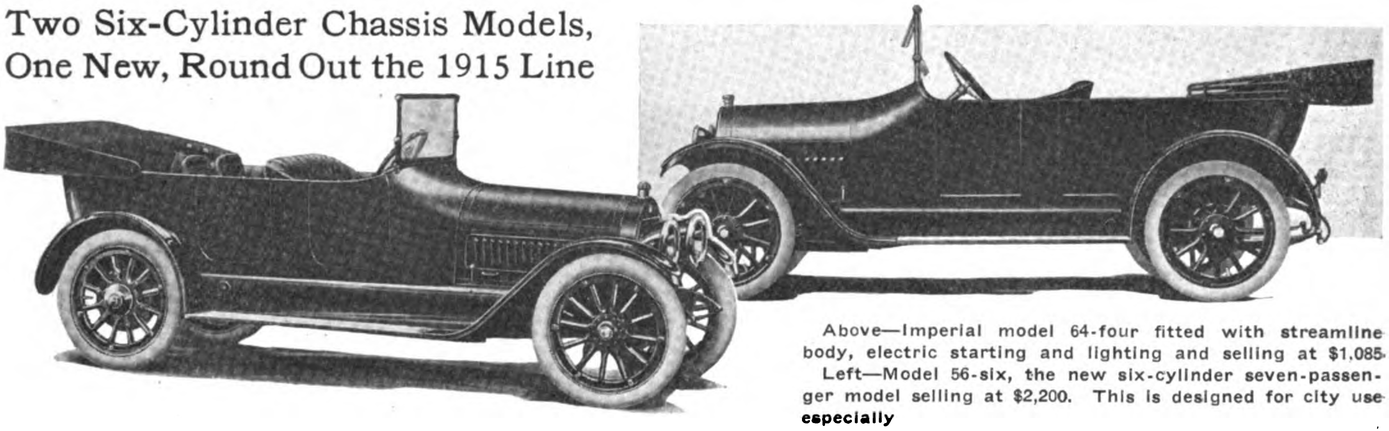
The top is a patented design which may be raised or lowered by one man in 30 seconds. The front is inclosed by two glass windows through which a full view of the road can be had by the passengers, because of the central position of the driver. Provision for baggage is made by installing a substantial trunk carrier in the rear.



Rear view of cab showing trunk rack

New Imperial Streamline Four at $1,085

Two Six-Cylinder Chassis Models, One New, Round Out the 1915 Line



Above—Imperial model 64-four fitted with streamline body, electric starting and lighting and selling at $1,085. Left—Model 56-six, the new six-cylinder seven-passenger model selling at $2,200. This is designed for city use especially

A FOUR- and two six-cylinder models comprise the 1915 line of the Imperial Automobile Co., Jackson, Mich. Model 64-four is the feature, listing at $1,085 or $415 lower than the previous four-cylinder model. It has a 115-inch wheelbase, 3 3-4 by 5 Continental L-head block motor rated at 22.5 A. L. A. M. horsepower, Gray & Davis starting and lighting system, thermo-syphon cooling, cowl fuel tank and streamline body with rounded radiator. Gills in the bonnet sides, smooth doors, concealed upholstery and well designed fenders add to its appearance.

The four-cylinder type mentioned and the 56-six listing at $2,200 are new models. The other six, model 44, selling at $2,000, is practically a continuation of the same model of 1914, except that many minor refinements have been made and the new type of body entirely alters its appearance. Continental motors with the cylinders cast in threes are used in the sixes and the streamlines of the bodies are consistent in all models.

The chassis of the four has a strong and light appearance with well-proportioned springs carrying the frame.

The motor has the gearset in unit, the whole being three-point suspended in the frame. The crankcase has two integral supporting arms at the rear while the front support is at the center. The usual aluminum crankcase construction, with the upper and lower parts horizontally split, is used. Valves are all on the right and inclosed by two cover plates. The exhaust header also is placed on this side, there being an individual opening into each cylinder from it. But the intake passages are cored in the cylinder casting and pass across to the left side, where they unite into one opening to the carbureter intake pipe. This has the advantage of simplicity outwardly and at the same time serves to heat the incoming gases which is a factor in efficient vaporization of the fuel.

Light-Weight Parts

The working parts of the motor are well balanced and their weight has been made as light as possible. The pistons, cast from the same grade of iron as the cylinders, are each fitted with three diagonally split rings, while oil grooves are turned in their surfaces to aid in oil distribution. I-beam connecting-rods attach to the pistons by means of steel tubing pins which are fixed in the pistons.

Low carbon steel is used for the camshaft, also a three-bearing proposition with integrally forged cams. This is driven from the front by the usual timing gear train, the gears being helically cut and completely housed. Conventional poppet valves are used.

The cooling of this engine is by thermo-syphon. Lubrication is of the combination force-feed and splash variety with a horizontal plunger pump, driven by an eccentric from the camshaft, forcing oil through copper tubes direct to the timing gears and front main bearings and over the rear main bearing. It then drains back into the oil pan.

Gasoline Tank in Cowl

The gasoline system of this car is new to Imperial practice in that the cowl type is used. A 10-gallon reservoir located in the cowl supplies the carbureter by gravity. The Atwater Kent Unisparker type of ignition is employed, this automatically adjusting itself to the speed of the engine.

In their application to the Imperial four, the Gray & Davis cranking and lighting units occupy their usual positions, the generator being driven by the external shaft connected to the front gears and on the right side of the engine. The cranking motor, which spins the engine at about 150 revolutions a minute, is placed so as to gear to the flywheel rim.

Unlike the preceding Imperial fours, the model 64 delivers its power to the rear through an uninclosed driveshaft. The intermediary members are a multiple steel disk clutch and three-speed selective gearset, both in unit with the engine.

The axle is a floating type which is fitted with Hyatt spiral roller bearings. Its axle shafts are removable without disturbing the rest of the construction. Twelve-inch brake drums with internal expanding and external contracting brakes are provided.

The spring suspension of this car is noteworthy on account of its easy riding properties. Seven plate oil tempered three-quarter elliptic rear springs 50 inches long and underslung from the axle suspend the rear of the chassis, while 38-inch springs of six plates take care of the front. All leaves are 2 inches wide.

Wheels are of the usual artillery wood type, to which are fitted Detroit demountable rims. They carry 32 by 3 1-2-inch plain tread tires.

The equipment includes a one-man top, electric horn, speedometer, windshield, dash lamps for illuminating the gauges and instruments, etc.

The New Six-56

The Imperial company characterizes this model 56 as a city car, although its seven-passenger commodiousness and luxury seem to invite the motorist to country roads as well.

A 3 3-4 by 5 1-4 engine of 33.8 A. L. A. M. horsepower is mounted on a chassis of 130 inches wheelbase. Its motor is somewhat different in general design from the four. The cylinders are cast in sets of three, valves are on the right and though integral crankcase arms support it in the frame at the rear, an arched cross member at the front serves as a support from which to hang the front center of the crankcase. The gearset is in unit, giving three-point suspension.

The crankshaft and camshaft are on three bearings, while drive of the camshaft and the magneto shaft are by helical gears. A silent chain runs from a sprocket on the crankshaft to the generator shaft sprocket on the left.

Cooling by Centrifugal Pump

Cooling by centrifugal pump in conjunction with a large cellular radiator is used, while lubrication is maintained by a force feed splash system whereby constant level in the troughs is insured by pump. The electric functions of cranking and lighting are cared for by a North-East combination motor and generator, driving through silent chain to the front of the crankshaft. This unit, with its two windings, acts first as a motor to start the engine, after which it becomes a generator for charging the storage battery and operating the lights.

A disk clutch connects the drive parts to the engine, while the gearset affords the usual three-speed changes ahead. The gears used are chrome vanadium and they are carried on nickel-steel shafts mounted on annular ball bearings. But unlike the new four, the propeller shaft is inclosed within a torsion tube which takes drive and torque. This shaft is 1 3-8 diameter, of chrome-nickel steel.

The rear axle is floating and has a malleable housing. Like the propeller shaft, the axle shafts are chrome-nickel steel. Their diameter is 1 1-2 inches. The axle ratio is 3 7-8 to 1. The brake drums are 16 by 2 1-4 inches.

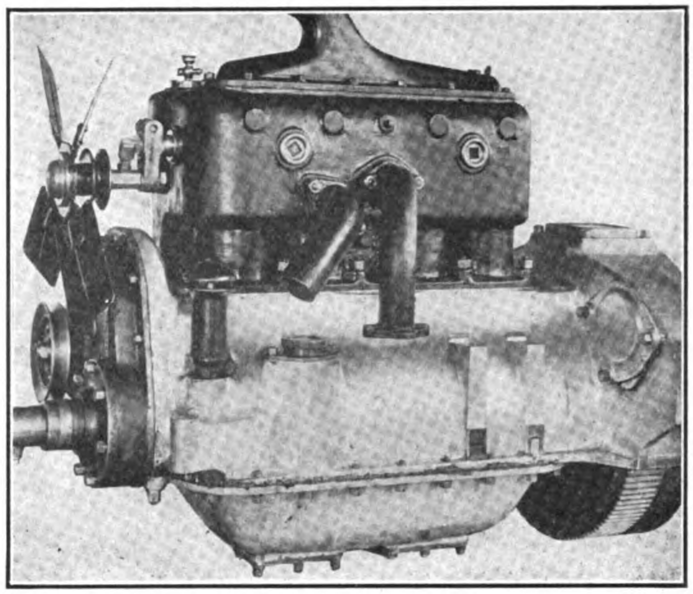
Body work on this car is specially attractive, the full streamline effect being carried out. The upholstery does not protrude over the top edges, and with clear running boards, doors with concealed hinges and inside handles, the outward appearance is exceedingly trim.

The wheels are fitted with demountable rims, and carry 36 by 4 1-2 tires all around. Complete equipment, which includes a one-man top, windshield, speedometer, electric horn and so on, is furnished. Left drive and center control are used, and the 20-gallon gasoline tank is carried at the rear. It feeds by the vacuum supply system to an auxiliary tank, and thence by gravity to the carbureter.

Model 44-Six

The other Imperial six, model 44, is a continuation of the same model of last season with new body. The motor, drive parts, etc., are the same as in the six just described. With its wheelbase 4 inches less—126 inches—this car carries a five-passenger body somewhat similar to that mounted on the 56. The inclosed driveshaft gets its power through a disk clutch and three-speed gearset. The floating rear axle has a ratio of 3 1-2 to 1, its housing being a pressed steel type rather than of the malleable form as used on the other six.

This model also has North-East cranking and lighting, carries complete equipment and uses 36 by 4 1-2 tires.



Four-cylinder Continental motor used on Imperial 64-four for 1915, showing clean design. Note large water passages for thermo-syphon cooling

Principal Dimensions of Motors in 1915 Imperials

PART	FOUR	SIXES
Valve diameter	1 11-16	1⅞
Crankshaft front bearing	2 3-16 by 2⅞	2 by 3¼
Crankshaft center bearing	2 7-32 by 2½	2¼ by 3
Crankshaft rear bearing	2¼ by 3	2 by 3⅞
Camshaft front bearing	2 19-32 by 1½	2¼ by 2⅝
Camshaft center bearing	2⅝ by 1⅛	2 by 1⅞
Camshaft rear bearing	1½ by 1¾	1⅛ by 2⅛
Piston pin bearing	1 3-32 by 1½	1 7-32 by 1⅞
Piston length	3¾	5
Connecting-rod bearing	1⅞ by 2 3-16	1⅞ by 2⅛

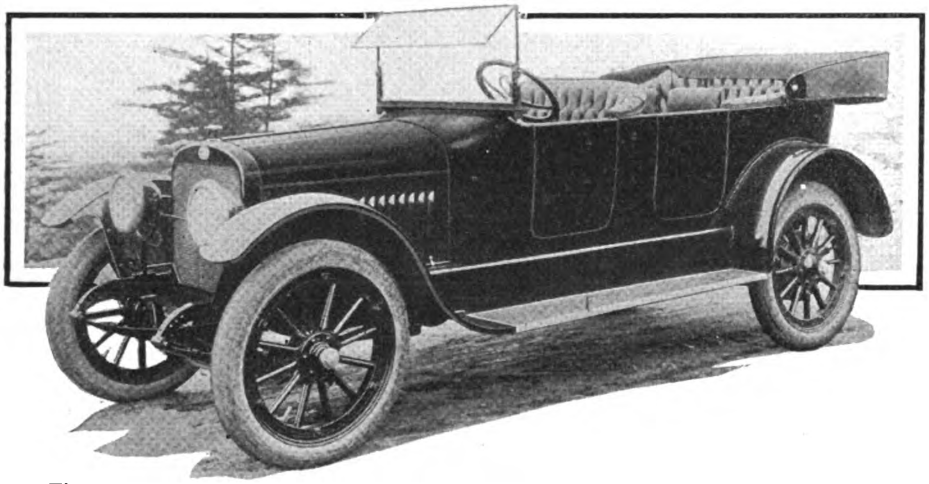
Enger Six to Sell for $1,495

1915 Model Has 50-Horsepower Motor and Weighs 2,865 Pounds—Standard Parts Used Throughout—Seven-Passenger Body Used



Three-quarters front view of new Enger selling for $1,495. It is fitted with a seven-passenger body

A SIX selling for $1,495 and equipped with a motor rated at 50 horsepower is the offering of the Enger Motor Car Co., Cincinnati, O., for 1915. The motor has a bore of 3.5 inches and a stroke of 5 inches, and is combined with clutch and gearset to form a unit construction supported on three points.

The weight of the car is 2,865 pounds, fully equipped with top, windshield, battery, lamps, starter, speedometer, tools and extra rim. The wheelbase is 124 inches and the clearance 10 inches.

A comfortable body of the streamline type, with gradual curves from front to rear, is mounted on the chassis. The body is capable of seating six or seven passengers, there being space for two or three on the back seat and two on auxiliary folding seats.

The running boards are clean of all obstructions, the tools being carried under the rear seat while the storage battery is hung from the frame. The slope of the cowl is unbroken as the side lights have been done away with, these being combined in the headlights.

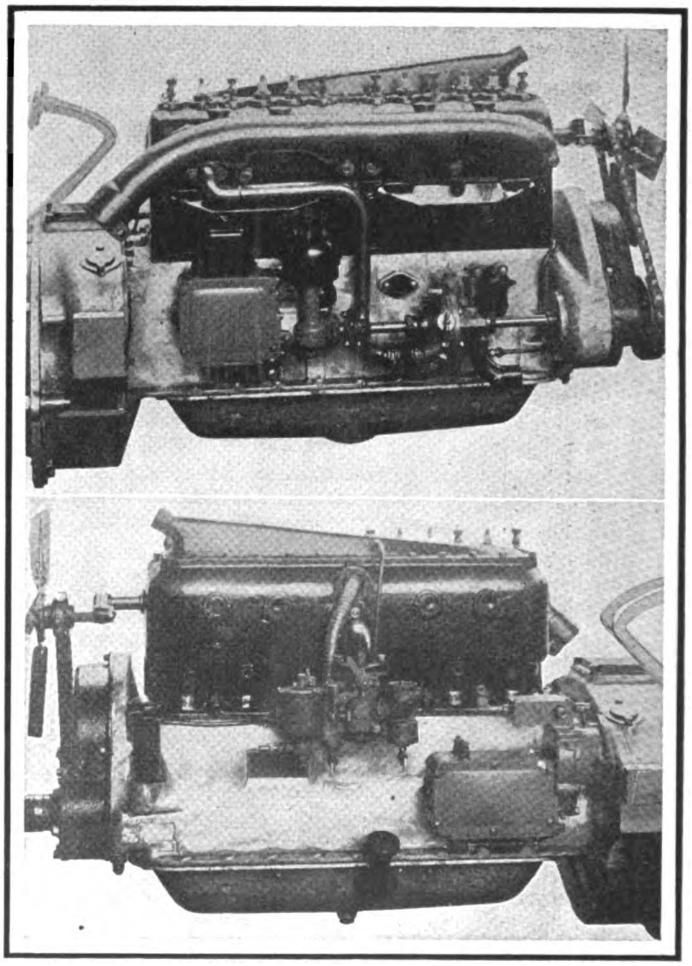
One-Man Top

The upholstery is from 10 to 12 inches deep and is made from leather. The top is a five-bow, one-man type with patented quick-adjustable curtains. On the cowl are found a Stewart-Warner speedometer, a gasoline gauge, and an electric indicator. All dials are electrically illuminated. The button for the electrically driven motor horn is mounted conveniently on the center of the steering post.

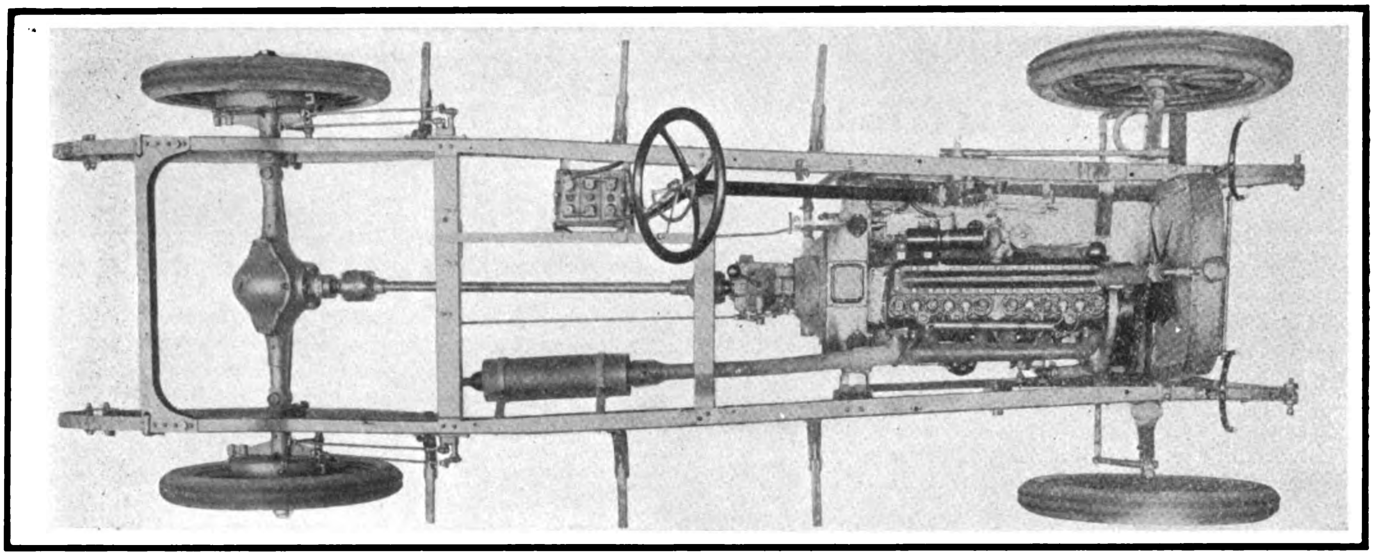
The motor is a Continental make, model 6-N. It is an L-head, block design with the valves on the right and fully inclosed. Also on this side are most of the motor auxiliaries. The shaft which drives the centrifugal water pump also operates the Atwater Kent Unisparker and the generator. The former is driven from the pump shaft by a bevel gear while the latter is directly connected. The four-bladed fan which aids in the circulation of the cooling air is driven by a sectional belt from a pulley attached to an extension from the front end of the pump shaft.

On the right side of the motor is the carbureter, and starting motor. The carbureter is mounted high and is very accessible. It is a Rayfield product, is fitted with a dash adjustment for starting and is water jacketed. The starting motor meshes with gear teeth cut in the flywheel rim. The oil breather and filler opening is located at the front on this side and there is also a gauge for determining the amount of oil in the crankcase.

Connection between motor and gearset is made through a multiple disk clutch which is housed in the flywheel which in turn is inclosed in a bell-shaped extension of the crankcase.



Two views of Enger motor. The upper one shows the right side and the mounting of the pump, sparker and generator, while the lower one shows the left side of the motor and the position of the carbureter, starting motor, breather and oil gauge



Plan view of Enger chassis, showing unit power plant suspended at three points, the position of the battery and the general arrangement of parts about the chassis

The gearset is bolted to this member. It is a three-speed sliding gear type. Gear changes are made through a lever which is mounted directly on the top of the case, which makes a very simple arrangement and is in accord with modern practice. Large inspection plates are provided in the clutch case, while the gears may be looked over by taking off the top cover which carries the shifting lever.

Power is transmitted to the rear axle through two universals. No torque or radius rods are used in the rear construction, the drive being taken through the springs, which are of the three-quarter elliptic type. The main leaves are constructed from vanadium steel and they measure 54 inches in length.

The rear axle is a floating type fitted with a diagonally placed differential cover plate so that the differential gears may be readily inspected or removed.

Two sets of brakes are employed. Both operate on the same rear wheel drums, one being contracting and the other expanding. They are faced with a special-treated friction material. Brake equalizers equally divide the force applied to each wheel.

The steering gear is mounted on the left. It is irreversible and is adjustable for wear. The wheel is of polished ebony and provision is made for easy lubrication of the gear.

Thirty-four by 4-inch tires are used all around, being fitted to Firestone demountable rims.

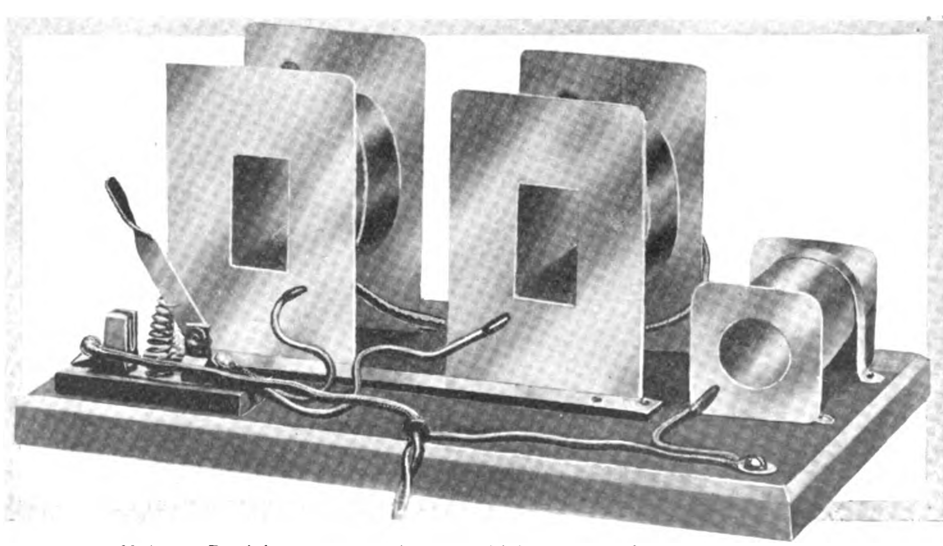
Metzger-Daniels Magnet Recharger Does Work in 6 Seconds

MAGNETO magnets may be charged in 6 seconds by means of a recharger manufacturer by the Metzger-Daniels Co., Portland, Ore. An ordinary 6-volt storage battery, or six dry cells in an emergency, may be used as the source of current. The device consists of two powerful electro-magnets compactly mounted on a suitable base, to which the binding posts and switch are fitted. When charging, a current of about 30 amperes is required, but the time during which it flows is so small that it does not injure the battery in any way, it is stated. In operating the instrument the switch is opened and closed intermittently, it being closed for about 2 seconds at a time.

To locate the correct charging position in relation to the polarity, the operator merely holds the magnet to be charged close to the rectangular openings in the coils, and makes a short contact at the switch. If the charging position is correct the magnet will be attracted by the coils, but if the charging position is not correct the magnet will be repelled. After locating the correct charging position the magnet is inserted in the coils so the ends of the magnet protrude through the coils. A piece of iron or steel is now placed across the ends of the magnet, and three contacts of the switch for about 2 seconds each will fully charge the magnet. The magnet may now be placed back on the magneto in the original position.

As the retentive qualities are dependent on the hardness and grain of the magnet it is difficult to establish a standard charge for any make of magnets, due to the varying quality.

The Metzger-Daniels magnet charger is guaranteed for a period of 5 years from date of sale, and the list price is $25.

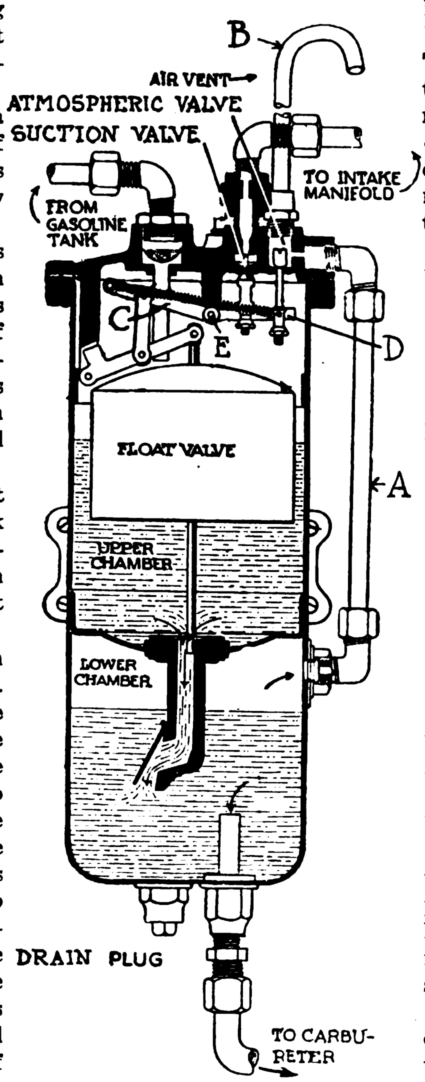


Metzger-Daniels magnet recharger which operates from a 6-volt circuit

Stewart Fuel Feed More Compact

Valve Mechanism Completely Housed Within Cylindrical Tank—One Atmospheric Vent

SEVERAL detail changes have been made in the Stewart Vacuum Gasoline system since it was described in the April 2, 1914 issue of THE AUTOMOBILE. The principle has not been altered but the design has been made more compact and simple. The valve mechanism is now contained entirely within the cylindrical housing while formerly it was located in an offset at one side. There is now but one atmospheric vent, while formerly there were two. These and other slight changes make a description of the device, as it now is, of interest, especially since the system has been made standard equipment on many 1915 cars.



Vertical section through tank housing Stewart-Warner vacuum system

In this system the suction of the motor is employed to draw gasoline from the main fuel tank to the carbureter, and with its use the tank can be located at the rear of the car the same as with the pressure system. It is claimed that all the advantages of the pressure system are obtained with very little more complication than is found on the ordinary gravity feed.

In common with the pressure system it has the advantage of the gasoline tank hung at the rear, yet it avoids the complication of the former by doing away with all pumps, gauges and reducing valves. Not even an air-tight tank is needed.

The actual construction of the mechanism is shown by the accompanying illustration. This mechanism is all contained in the cylindrical tank shown, which may be mounted on the front of the dash or on the motor as desired. The tank is divided into two chambers, the upper one being the filling chamber and the lower one the emptying chamber. The former contains the float valve and the pipes running to the gasoline tank and to the intake manifold. The lower chamber is called the emptying chamber and from it runs the pipe to the carbureter. This chamber is under atmospheric pressure at all times and the flow of fuel from it is by means of gravity only. However, since this chamber is located somewhat above the carbureter there is always a free flow of gasoline. Atmospheric pressure is maintained by means of the pipes A and B, the latter opening into the atmosphere.

Referring to the accompanying illustration it will be seen that in order that fuel may be sucked from the main tank to the upper chamber the suction valve must be open and the atmospheric valve closed, the float then being at the bottom. Under these conditions the suction at the intake manifold draws the gasoline from the main tank to the upper chamber. When the upper chamber is filled, the float rises to the top, closing the suction valve and opening the atmospheric valve. Thus the suction is cut off and the lower chamber is now filled by gravity, there being atmospheric pressure in both chambers now. The flap valve between the two chambers is to prevent the gasoline in the lower chamber from being sucked back into the upper one.

The float is designed to be intermittent in its operation. When the level of gasoline drops to a certain point, the float falls, the suction valve opens and the atmospheric valve closes. The suction of the motor then causes a flow of fuel from the gasoline tank. Then, when the level rises to a predetermined height, the float returns to its upper position. It takes about 2 seconds for the chamber to become full enough tc raise the float—.05 gallon being transferred.

The atmospheric and suction valves are controlled by the two levers, C and D, both of which are pivoted at E, their outer ends being connected by two coil springs, only one of which is shown in the illustration. It is seen that the arrangement of these two springs is such that the float must be held at the extremity of its movement. It cannot assume an intermediate position. This intermittent action is required in order that the upper chamber may be under atmospheric pressure part of the time in order for all gasoline to flow to the lower chamber. It will be noted that the movement of the float mechanism is so large that no adjustment is needed on the valves.

The pipe running from the bottom of the lower chamber to the carbureter extends up into the chamber, so that there is little chance of dirt or water being carried to the carbureter. A drain plug is provided to the left of this pipe for cleaning out dirt.

Few Parts to Wear

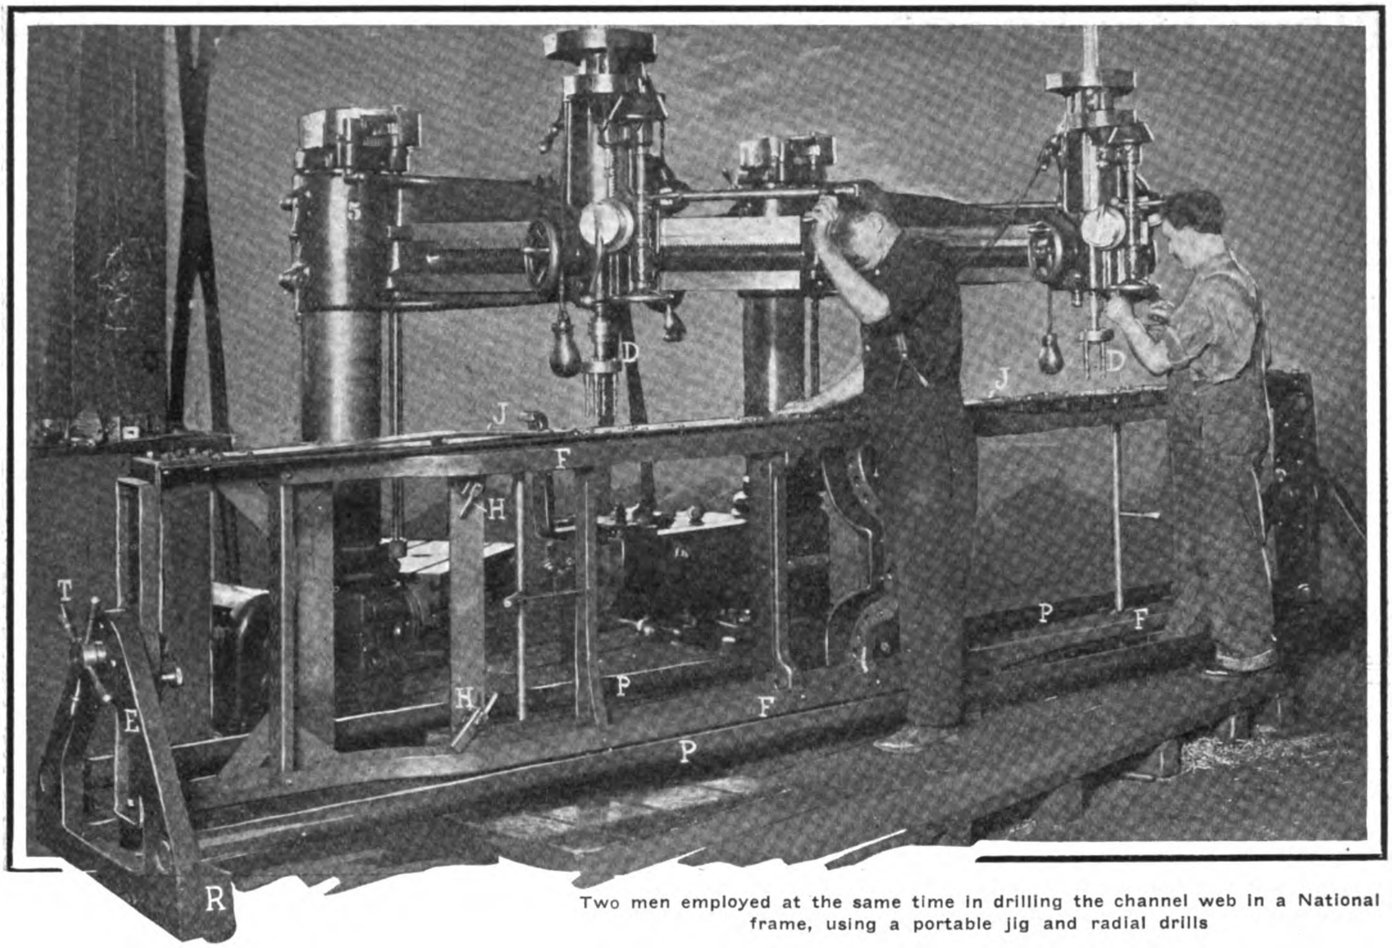
Great durability is claimed for this device because there are few parts to wear. The springs are made out of No. 28 gauge bronze and have a stretch of only .125 inch, so they should last a lifetime.

The only time that the vacuum can become so low that it will not draw gasoline from the rear tank is when the tank pressure is below 4 ounces, and this condition can exist only when the motor is running below 600 revolutions per minute with wide open throttle. In actual practice a car is never operated under these conditions long enough to exhaust the supply of fuel in the tank. Running with open throttle below a speed of 600 revolutions per minute means that the motor must be laboring up a hill, and as this is detrimental to the motor the Stewart-Warner system acts as a safeguard.

If the car is allowed to stand long enough so that the tank becomes empty it will be replenished after the motor has been cranked over four or five times with the throttle closed.

The installation of the Stewart-Warner vacuum-gravity system is very simple and can be accomplished in a short time without the use of any special tools. The suction pipe is tapped into the manifold at a point as near to the cylinders as possible, while the fuel pipe is inserted into the gasoline tank and runs to the bottom. There is a screen at the end of the fuel pipe to prevent any trouble due to sediment. Since the fuel is sucked from the gasoline tank, the filler cap need not be air-tight but on the contrary should be provided with a small vent so that the pressure in the tank will be at atmosphere.

It is manufactured by the Stewart-Warner Speedometer Corp., Chicago, Ill.



Two men employed at the same time in drilling the channel web in a National frame, using a portable jig and radial drills

Portable Jig Aids in Drilling National Frames

Clamping Frame in Jig and Rolling It Under Two Radial Drills Saves 50 Per Cent. in Time

FRAME drilling in the National plant at Indianapolis is accomplished by an ingenious jig. Instead of having to resort to the setting up of multiple spindle drills for each different series of jobs to be done on the frame, it is merely clamped in the jig and rolled under a pair of radial drills as shown in the accompanying illustrations. The drills are made up in sets and setting up is accomplished in minimum time.

Referring to the illustrations, the frame F is clamped in the jig J by means of the dogs H. The jig is composed of two end castings E, and large tubular connecting members P. Inside this framework the jig is free to swing on a pivot support at its center. The jig can be held in any desired position by turning the hand nuts T. The radial drills D, are all made up in sets and the workmen merely have to clamp them in the chuck.

In order that the work will be as convenient as possible there is a platform for the men to stand upon and the end pieces for the jig have been so constructed that the rollers lift the jig above the platform and it can be rolled into position without interference.

Two men can work at the same time on the frame, one handling one of the radial drills and the other handling that on the other end of the frame. When the two are through their work, the frame is simply turned over by loosening the hand nuts. The drills are then all set up for work on the other side. The frame is put in the jig to one side of the drills where there is a clear floor space for the purpose. It is quickly slipped in place in a horizontal position and the dogs clamp it in the proper position. The jig is then turned up on edge to bring the frame in proper position for the work and the entire outfit is rolled under the drills. It is estimated that a cut of at least 50 per cent. in the required time for frame drilling has been effected by this system.

National frame in jig placed beneath the radial drills. When one side is drilled the jig can be rotated with the frame

New Books for the Engineer

A WEALTH of motor literature is submitted by British publishers. Most complete of these, from an engineering standpoint is A Manual of Petrol Motors and Motor Cars by F. Strickland, Charles Griffin & Co., publishers. Others take up Motor Traction, Petroleum Storage and several subjects pertinent to motor car manufacture. *The Autocar*, through Iliffe & Co., has published some interesting and instructive handbooks on motor car troubles.

A MANUAL OF PETROL MOTORS AND MOTOR CARS. By F. Strickland. Second Edition. Charles Griffin & Co., Ltd., Exeter street, Strand, London. Cloth; 378 pages; 352 illustrations; 18 shillings.

This book sets forth clearly and concisely everything concerning a motor engine from its history to calculations of curves of inertia, and pressure and differential gear stresses. All matter is, however, so simply conveyed that it would make itself clear to the most veritable novitate. Effort has been made to show the amount of power necessary for cars of given weight, with figures, as to engine stress.

MOTOR TRACTION FOR BUSINESS PURPOSES. L. M. Meyrick Jones, A.M.I., Mech. Eng.; and Horace Wyatt, B.A., from data collected by the editorial staff of *Motor Traction*. Iliffe & Sons, London, publishers.

This book is a guide to the selection, cost of running and maintenance of commercial and public service motor vehicles. In it are taken up the general conditions governing the adoption of motor haulage, legal restrictions and the working costs of almost every form of motor tractor.

All data has evidently been carefully compiled and thoroughly considered. This book should prove itself valuable to anyone contemplating the purchase of motor vehicles.

A PRIMER ON THE STORAGE OF PETROLEUM SPIRIT AND CARBIDE OF CALCIUM. By Major A. Cooper-Key, Chief Inspector of Explosives and Member of the Council of the Institute of Petroleum Technologists. Charles Griffin & Co., Ltd., London, publishers. Price 2 shillings 6 pence.

Devoted to a consideration of the best means of effectively administering the Petroleum Acts. Taking up from the viewpoint of the inspector of explosives, the things which are necessary for keeping within the law in handling petroleum and calcium carbide. Points are given on proper licensing, together with possible future legislation.

HYDRAULICS. By W. M. Wallace, Wh. Sc., A.R.C., Sc. A.M., I.C.E., The Technical Publishing Co., London, W. C.

For engineering students and engineers in practice. Including recent research and invention in hydraulics. The first part of each chapter, deals with the main principles in easy language, leaving the more mathematical demonstrations to the second part, examples at the end of each chapter being graduated similarly. As far as possible the author has avoided using the hydraulics as a peg on which to hang essentially mathematical demonstrations which lead to results, the truth of which, more often than not depends on somewhat arbitrary assumptions.

SMALL ACCUMULATORS. By Percival Marshall, A.I. Mech.E. Spon & Chamberlain, publishers, 123 Liberty street, New York City.

A scientific hand-book for students and engineers, published in answer to the questions sent the author as Editor of *The Model Engineer and The Amateur Electrician.* Setting forth the making of storage batteries and cells, methods of charging and governing.

COMPLETE HINTS AND TIPS FOR AUTOMOBILISTS. From *The Autocar*. Iliffe & Co., London, publishers. Fifth Edition. Price 2 shillings 6 pence, net.

Compiled from the many inquiries, and the answers they have elicited in *The Autocar*, of London., since 1902. The booklet contains an index, giving immediate access to the explanation of the best means of overcoming motor-car difficulties.

FAULTS AND HOW TO FIND THEM. Iliffe & Sons, London. Edited by J. S. V. Bickford, B.A. Price 2 shillings 6 pence.

Containing a list of 180 faults in motor cars and their remedies. This book covers about everything that could happen to an automobilist in the course of his travels.

THE MOTOR MANUAL. The Temple Press, London, publishers. Price 1 shilling 6 pence.

A simple description, fitted for amateurs, of the working parts of cars together with remedies for faults which may crop out. Every part of the motor is described carefully. Much space is devoted to explanations of motor starters and electric lighting. Concise information is given of all recent developments.

Many new hints are also given in repairs and adjustments.

The fuel question is taken up quite exhaustively, with several pages devoted to benzole, which is taken as the only practical substitute for gasoline.

THE MAINTENANCE OF MOTOR CARS. By Eric W. Walford. Iliffe & Sons, publishers. Price 2 shillings 6 pence.

For the large number of owners who have had little or no motor car experience. Descriptions are for this reason, made as clear as possible, the assumption being made that the reader has not much technical knowledge, also removing many of the bogies that haunt prospective buyers of automobiles.

PUNCHES, DIES AND TOOLS, FOR MANUFACTURING IN PRESSES. By Joseph V. Woodworth, the Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 500 pages, 702 illustrations, $4.

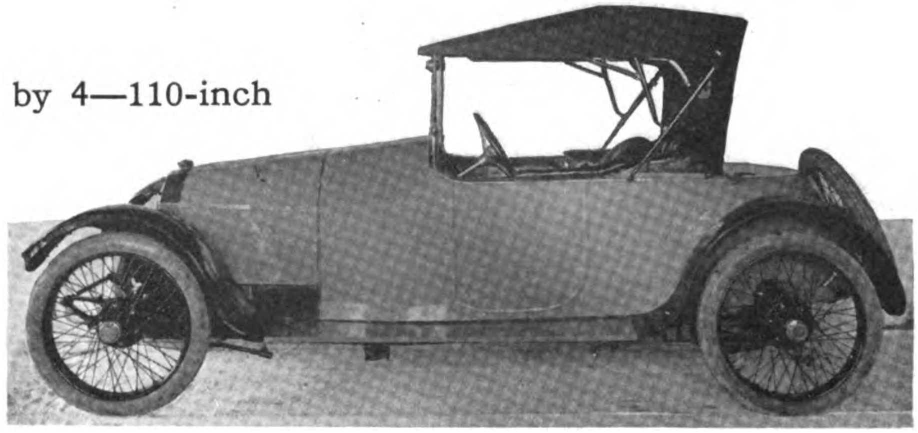
This work is a companion volume to the author's elementary work entitled Dies, Their Construction and Use. It does not go into the details of die making to the extent of the author's previous book, but gives a comprehensive review of the field of operations carried on by presses. It might well be termed an encyclopedia of die making, punch making, die sinking, sheet metal working, and making of special tools, subpresses, devices and mechanical combinations for punching, cutting, bending, forming, piercing, drawing, compressing and assembling sheet metal parts and also articles of other materials in machine tools.

DIES, THEIR CONSTRUCTION AND USE FOR THE MODERN WORKING OF SHEET METAL. By Joseph V. Woodworth, the Norman W. Henley Publishing Co., 132 Nassau street, New York City. Cloth, 384 pages, liberally illustrated, $3.

A most useful book, and one which should be in the hands of all engaged in the press working of metals, treating on the designing, constructing and use of tools, fixtures and devices, together with the manner in which they should be used in the power press, for the cheap and rapid production of the great variety of sheet metal articles now in use, It is designed as a guide to the production of sheet metal parts at the minimum of cost with the maximum of output. The hardening and tempering of press tools and the classes of work which may be produced to the best advantage by the use of dies in the power press are fully treated. Its 505 illustrations show dies, press fixtures and sheet metal working devices, the descriptions of which are so clear and practical that all metal-working mechanics will be able to understand how to design, construct and use them. Many of the dies and press fixtures treated were either constructed by the author or under his supervision. Others were built by skillful mechanics and are in use in large sheet metal establishments and mechanic shops.

Luxury at $775 in New Scripps-Booth

Four-Cylinder Motor 2 7-8 by 4—110-inch Wheelbase—Electric Door Openers—Electric Starting and Lighting—Wire Wheels—Three Body Types

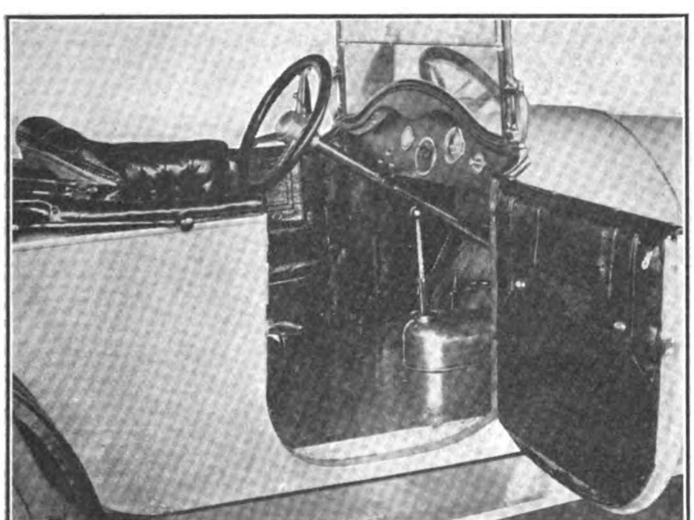


Side view of new streamline Scripps-Booth light car which sells at $775 with complete equipment including electric lighting and starting and wire wheels. The frame is overslung instead of underslung as shown in the illustration

THE new Scripps-Booth car to succeed the cyclecar which this concern brought out a year ago, is one of the most luxurious types of automobiles in its class, which has been brought out. Fitted with a four-cylinder motor 2 7-8 by 4 inches bore and stroke, with 110-inch wheelbase, with 30 by 3 1-2-inch tires, and with such up-to-date equipment as motor-generator for engine cranking and lighting, Houk wire wheels, electro-magnetically controlled doors, electric horn, 9-inch upholstery in the seats, and many other details, show how the Scripps-Booth Co., Detroit, Mich., has endeavored to produce a car with all luxuries at $775 as a roadster. This price includes equipment, such as an extra wire wheel with tire, silk mohair top, rain-vision windshield, side curtains, and Klaxet electric horn.

The new Scripps-Booth is made with an option of three treads, 40, 56, or 60 inches. In addition to the four-cylinder motor with an S. A. E. rating of 13.25 horsepower, but claimed to show 19 in actual performance, the car makeup includes cone clutch, three-speed gearset, shaft drive, and double set of rear wheel brakes. The chassis frame is overslung in front on semi-elliptic springs. In the rear cantilever springs, giving a 7-inch radius of action, are employed.

It is in connection with the bodies that the luxury of the Scripps-Booth appears. It is made in three body styles, namely, roadster, cabriolet, and coupé, all with three passenger capacity. The roadster sells at $775. This body has come under the hands of a clever designer for it is exceedingly attractive. It is a streamline type with a decided slope to the bonnet. The effect is carried out by a V-shaped radiator of German silver, and by continuing the bonnet slope back to the end of the cowl. The rear is given the torpedo shape, and this is attractively set off by the mounting of a spare wire wheel on the deck.



Control features of new Scripps-Booth, showing left drive and center gearshift as well as arrangement of instrument board

Seating is well worked out. The drive seat is placed slightly forward of the passenger seat which gives a modified staggard arrangement, and ahead of this there is mounted an auxiliary folding seat to accommodate a third person. Deep Turkish upholstery of long-grain buffed leather, unusual in a car of this type and price, and having a depth of 9 inches is used.

Electric Door Opener

One entirely new feature is the use of electric door latches, eliminating entirely door handles of any form. A push button, placed close to the door in the side of the body, operates the latch magnetically. Domed fenders do their part in making the machine attractive, and with wide doors and clear running boards the body meets every requirement of the most fastidious. The door width, to be exact, is 21 inches.

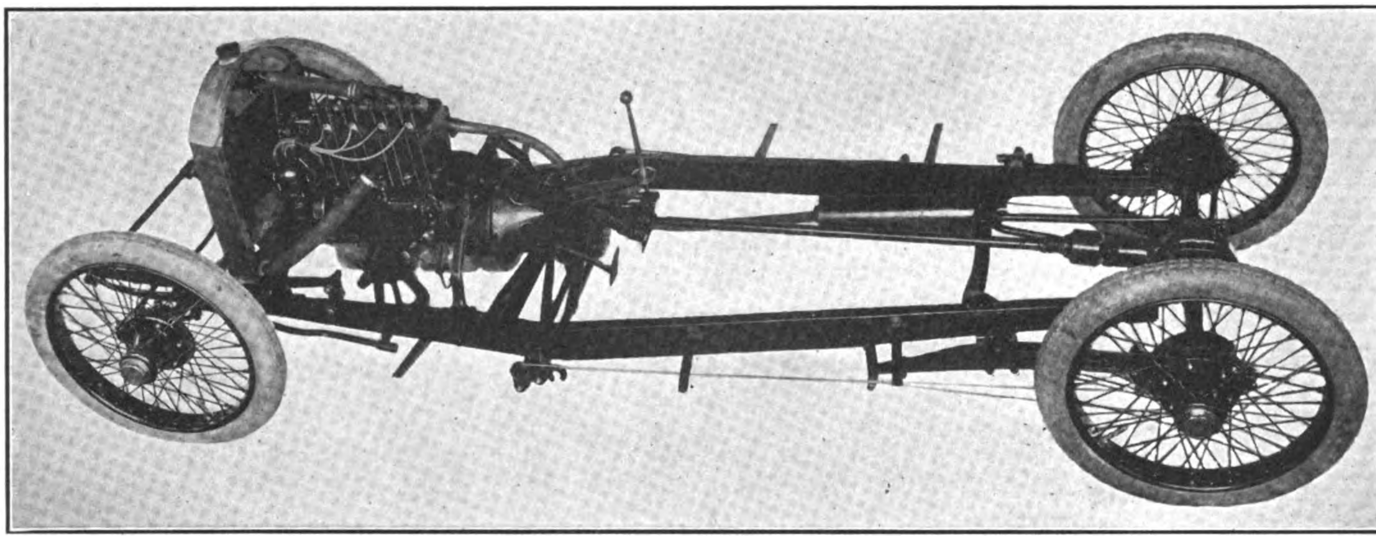
The drive is on the left, a 16-inch walnut steering wheel being used. On this, there is a throttle lever swinging vertically, and an unusually large push button operates the Klaxet horn. This is a domed aluminum affair placed at the center of the steering wheel spider and having a 3-inch diameter to make horn signalling as easy as possible.

On the cowl board are arranged the sight feed oiler, the starting strangler on the carbureter, ignition switches, ammeter, and flush-type speedometer. A dash light in the center illuminates these. Back of the cowl board is the gasoline tank with filler protruding through the board.

Three-Point Suspension

The power plant is of the unit type with gearbox bolting to the rear of the flywheel housing. This assembly is supported in the frame by arched cross members, from which it is hung by bolts, there being two points of attachment to the rear cross piece and one to the front, giving the well-known three-point suspension.

The motor is really a high-speed type and is made by



Scripps-Booth chassis, showing tapered frame, cantilever rear springs and mounting of the four-cylinder unit power plant

Sterling. It attains speeds as high as 2,750 revolutions per minute without appreciable drop in the power curve.

Silent operation has been well attained by the special design of the cams which allow the valves to drop to within 1-1000-inch of their seats and then slowly lets them down the remaining minute distance. These valves have a clear opening of 1 1-8 inches.

The general arrangement of the cylinder block is of the form in which the crankcase and the cylinders are cast in one piece, the head carrying valves and passages to the intake ports being detachable. Rods run up from the camshaft to the rockers overhead operating the valves, and are very silent in action. The exhaust manifold is a separate piece and bolts to the cylinder head. Access to the main bearings is possible through the large plate at the bottom of the crankcase. The crankshaft is carried on two main bearings, and the camshaft has three.

The oiling is of the circulating splash type with a small pump supplying a constant level of lubricant to the individual troughs under each connecting rod. Provision is made for assuring a constant trough level despite the angle of the motor.

Thermo-syphon cooling is used and the radiator is a cellular type of large capacity.

Ignition has no connection with the motor-generator for cranking and lighting, except that the distributer receives its current from the same battery as is used for the balance of the electric functions. The distributer is an Atwater Kent with automatic advance, there being no hand control.

Motor-Generator System

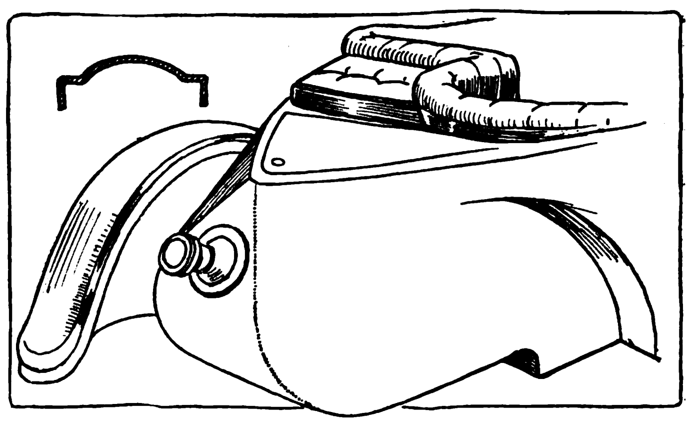
Hung from an integral bracket on the right side of the crankcase is the combined motor-generator which operates either as an electric motor for cranking or as a generator for supplying lighting current and charging the storage battery. This electric unit is driven through silent chain connection direct to the crankshaft. A sprocket placed just ahead of the flywheel on the extension of the crankshaft accommodates this chain. On test, this starting motor has spun the engine at 265 revolutions a minute for 12 minutes at a temperature of 60 degrees.

The headlights are of the two-bulb type, the small bulbs dimming the lamps for city work. The storage battery is conveniently located in a compartment just back of the driver's seat in the roadster.

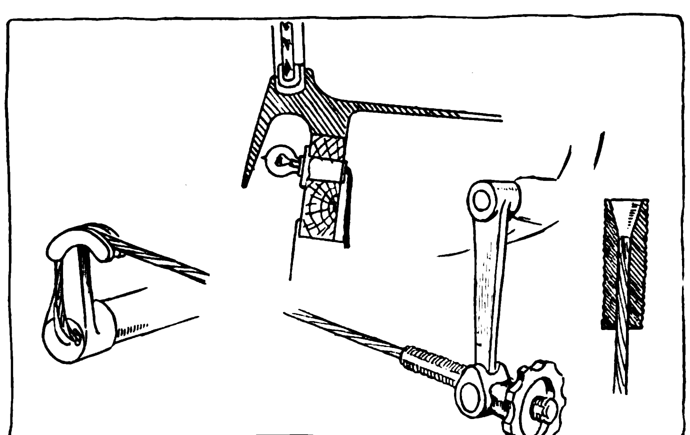
Cone Clutch Used

The clutch is a leather-faced cone and back of it is the three-speed selective gearset. Unusually large gears are employed of the substantial stub-tooth variety. These gears have a face width of 5-8-inch, and are constructed of 3.5 per cent. nickel steel. The control lever, of the ball-and-socket type, is mounted at the rear of the gearbox and gives center control.

A 1 1-4-inch tubular drive shaft, uninclosed, conveys the power to the rear axle. Though light in weight, this shaft is strong and proof against whipping due to its tubular section. Both front and rear ends of the shaft are fitted with a new type of universal joint, manufactured by the Universal Products Co. These are of ball type and allow for end play of the shaft due to the varying position of the rear axle with respect to the chassis.



Rear construction of Scripps-Booth with bracket for carrying spare wire wheel. At upper left is shown a cross section of the fenders



Above is shown the electric lamp on the instrument board so arranged as to shield the passengers while throwing the light on the instruments. Below is shown the novel brake adjustment

The drive is taken through the springs, while a triangular torque arm of tubular construction takes the torque. This arm hinges to the rear axle housing, and has a spring buffeted attachment at its front end to a frame cross-member placed only a short distance forward of the rear axle. The result of this construction is that the torsion member is exceedingly short, and therefore light in weight.

The rear axle, which is a specially designed type, is of floating construction. Very large gears are used, these being of six pitch and having 1 1-4-inch face. The pinion is one piece with the pinion shaft, while the whole mechanism is carried on annular ball bearings. Three and a half per cent. nickel steel is used in making the gears.

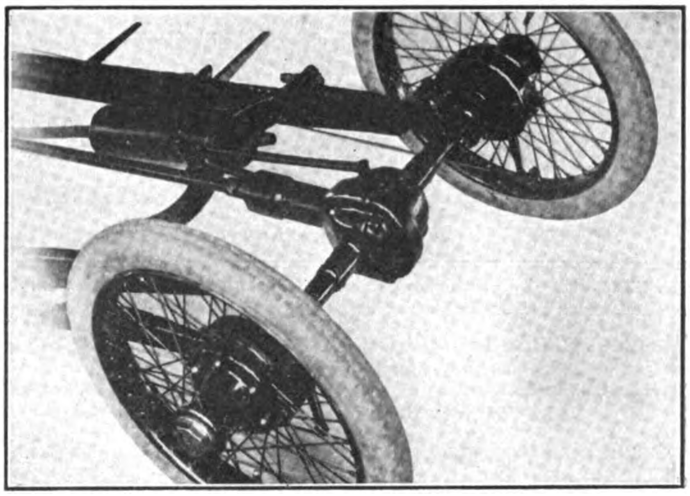
New Frame Shape

In order to give a substantial support to the body, which slopes to both front and rear, the frame is of unusual shape, having a taper forward as well as to the rear. The widest part is a little forward of the center of length where the body is widest. This is about at the cowl. The pressed steel channels have a 4-inch depth of section and are well braced.

The chassis is underslung due to the use of semi-elliptic front springs carried over the tubular front axle, and cantilever rear springs. The latter are 32 inches long and have a 7-inch vertical action. Due to the small amount of unsprung weight, the car is very comfortable to ride in.

Pedals for Brakes

The braking system is unusual in several respects. Though both service and emergency sets operate on rear wheel drums, they are both controlled by pedals instead of the emergency set working through hand lever. The clutch pedal operates the service set as well as the clutch, while the emergency pair are brought into action by the pedal to the right of the clutch pedal. This latter is fitted with a ratchet to hold the brakes. Steel cables run from the equalizers back to the brake drums, and adjustment is made very easy through the use of small hand adjusting wheels at the drums. These steel cables not only are a factor for lightness, but they are obviously free from rattle. They have very often been used on racing cars.



Rear construction of the Scripps-Booth showing the cantilever spring supporting the rear ends of frame, mounting of muffler, etc.

Des Moines Garage Adds to Appearance of Residential Section

THE Brown Garage, operated by the Brown Garage Co., Des Moines, Ia., which was recently opened by a show, and a convention of the automobile men of that city, has many unusual features. The garage, which is two stories in height, is built of light brown stone. The front is made attractive by potted plants and flowers placed in all the windows, making the garage, although in a residential district, a decided addition to the appearance of the section.

Interior improvements are many. Each car stall, which is 8 feet square, is equipped with air, water, electric light and a ventilator. An outside runway leads from the street to the second floor, thereby making unnecessary the use of an elevator, with its attendant delay and possibility of accident.

Three oil tanks with a capacity of two barrels each, are located in the rear of the building. Nine oil pumps are located in the basement and two upper floors. There is also a large gasoline pump at the curb. Air and water taps are also mounted in two boxes at the curb at each end of the building.

The garage is constructed of steel and concrete throughout, and is absolutely fireproof. The entire rear of the building is of steel and glass, giving it plenty of light. The front doors are opened and closed by electricity.

Brown Garage in Des Moines, Ia., which is rendered attractive by means which unfortunately are unusual in garage construction

Industrial Welfare Conference November 17-19

HARRISBURG, PA., Nov. 2—A call for second conference of the Pennsylvania Industrial Welfare and Efficiency Conference has been made. This will be held in the State Capitol, this city, on November 17, 18 and 19. This conference is held under the auspices of the Pennsylvania Dept. of Labor and Industry and the Engineers' Society of Pennsylvania. The purpose of the conference is to enable the employers and employes to work out together the problems before them with reference to increasing the welfare of the employes and the prosperity of the industries.

Careless Iowa Motorists Warned

DES MOINES, IA., Nov. 2—The Iowa State Highway Commission has issued a bulletin showing that sixteen Iowa people were killed at railroad crossings in the state during August; that three lost their lives as the result of reckless speeding on country highways; that two were killed as the result of narrow grades and bridges. The commission warns Iowa people against reckless driving and against careless approaches to railroad crossings. Six of the nine accidents at railroad crossings were due to trains striking automobiles. Five deaths were due to trains striking horse-drawn vehicles.

NEW YORK CITY, Nov. 2—Deliveries on the Singer Six have commenced by the Singer Motor Co., Inc.

Fewer Roadsters

THE policy of several makers of gasoline cars not including roadster bodies for next season, suggests the thought that for touring the four or five-passenger car is really the more comfortable, and comfort must never be lost sight of when making a tour. The roadster offers a most attractive vehicle for fine weather and general service but is not so inviting for long-distance work where baggage must be carried as well as passengers.

At first thought it seems bad business not to meet the demand for single-seated cars, but several good reasons for this policy can be found. In the first place, there is only a small patronage for the roadster body type as compared with the sales of five-passenger designs. In nearly every case where roadsters are offered, they go on the same chassis as a touring car, and therefore a machine carrying the former body is really designed for a slightly heavier one, and can carry it just as well.

So far as the mechanism is concerned, so far as fuel and oil consumption and tire wear are to be considered, it costs nearly as much to operate one as the other. One can make as much speed as the other for all practical purposes, and the business man is beginning to think it just as well to be able to carry three extra persons when he wants to as to be limited to only one besides himself.

Looked at from the manufacturing standpoint, the concentration upon one body model is desirable for it is less expensive to make a certain number of one type than to equal that number with more than one.

In the low-priced field, where the dollars count most to the buyer, he will recognize the advantage of the two-seated car more and more, and the result will soon be that only the higher-price car makers will be offering roadsters, for their trade can afford to waste power.

Touring in Electrics

IT still remains a most disputed problem as to whether the electric vehicle should be looked to to play any part in long-distance touring or not. On one side are ranged those who believe that the electric in its present status is not well suited for such work. On the side opposite are those who think otherwise. In general manufacturers do not believe that the present electric should be used for country touring on the ground that it has rather been designed for city use.

From the standpoint of arbitrary mileage there are many sections in the East where charging stations are close enough together to admit of using the electric for much country work. In these sections at present the electric is not generally used for this work, largely because those who do the touring are often undecided as to the exact distance they want to make, and distance is the great criterion of the success of the electric for touring.

The electric today is so dependable a vehicle that it can successfully be used in trips between cities where the distance is less than the battery mileage. In this capacity it acts as a substitute for the suburban trolley or the steam train.

But touring in the accepted sense goes further. Touring today has a more comprehensive meaning than it had 5 years ago. Today touring is getting more and more off the beaten path. It is not so much mileage as the desire to reach places that have hitherto been looked upon as inaccessible. In this sense it means getting away from those sections where the charging station is found and naturally the electric suffers in this respect.

But there is another side to the question, namely, that touring today does not mean mileage solely as it used to years ago. Today there is more thought of comfort, and having an opportunity to see the country, rather than endeavoring to make as many miles as possible. In this respect the electric is more favored than it was some years ago.

Before the electric reaches the stage of being taken seriously as a vehicle for country touring it will have to be more adapted to the needs of touring. The lighter open body will take the place of the palatial closed types of today, which are so well suited for city uses. The lighter body will add to mileage possibilities and will also give the tourists an opportunity of seeing the country, which still remains a valuable factor in touring. The field of inter-city work for electrics can also be cultivated.

Should Test Motors on Spring Chassis

Metropolitan S. A. E. Hears That Mounting of Motors on Rigid Test Blocks Is Wrong—Prof. Riedler's Work

NEW YORK CITY, Oct. 29—At the regular monthly meeting of the Metropolitan Section of the Society of Automobile Engineers which was held at the Automobile Club of America to-night, Professor Marshall discussed the work of Dr. A. Riedler in the laboratory for motor cars at the Royal Technical University, Charlottenburg, as recorded in Dr. Riedler's book, "The Scientific Determination of the Merits of Automobiles."

The book, which is published in English by the General Oil Publishing Co., Ltd., 6 Broad Street Place, London, E. C., contains 333 pages and 227 illustrations. The reports on tests of motor cars include all types from those of a military transport wagon running 10 miles per hour up to a 100-horsepower racing car with a speed of 90 miles per hour.

While the report is supposed to be unbiased, deductions have been drawn which are most favorable to German-made cars and motors. Further, the German cars were in perfect adjustment and were of modern construction, which was not always the case with the foreign cars.

The book is divided into ten reports: 1—To explain the test stand used and the methods of testing; 2—the investigation of a 30-horsepower Renault car; 3—test of a 100-horsepower Benz racing car and comparison of the Benz and Renault; 4—test of a 75-horsepower Adler racing car; 5—Mercedes electromobile; 6—35-horsepower Bussing military transport wagon; 7—test of the motor for the above wagon; 8—slide valve motors, method of test—comparison with poppet valve motors; 9—test of a 40-horsepower English Daimler-Knight car; 10—conclusion of reports 1-9.

In all these reports Dr. Riedler has used diagrams freely, the most common being those showing the energy, running, gradient and power losses in the various parts of the car.

Other diagrams are the acceleration, specific power, efficiency, opening of suction pipe and ports of Daimler-Knight.

There are several half-tone cuts of complete cars and of motors; also many line drawings of chassis and details of motors which were tested.

The testing apparatus was of the drum type with dynamo brakes. The rear wheels of the car were supported on these drums, the front wheels were placed on small plates resting on roller bearings, and the car was prevented from moving forward by means of a cable attached to the rear, which was also used in connection with the measurement of the draw bar pull.

The conclusions drawn were as follows: The correct investigation of power vehicles assumes accurate measurements corresponding to the actual working of the motor and car. In these tests accuracy was made doubly sure in most cases by two methods of measuring entirely independent of each other. The mounting of motors on rigid test blocks is wrong. They should be on spring chassis. The testing requires trained and clever attendants and not a staff kept by makers of cars for running in motors. It is a mistake to use car test stands as a substitute for the running in of cars. Not much has been done to increase the thermal efficiency of motors. The small amount of gearbox losses shows the futility of efforts to improve the driving members of cars. The power curves of the Benz and Adler motors show that the motor power increases almost directly with the speed. Economic operation of motor cars and trucks especially shows that economy is inseparably bound up with low traveling speed. In the interest of road maintenance only rubber tires should be used. The resistance of iron tires is large. Springing in the drive is of great value for working of the motor clutch. At low speeds, the flywheel greatly influences the acceleration and retardation conditions.

Much Valuable Data

Professor Marshall goes on to conclude that Dr. Riedler's reports contain much of value to the engineer regarding the various losses in the transmission of power in the various types of automobiles. There is nothing new in his method of testing cars on brake drums by means of electric motors connected to these drums.

By omitting many details which he terms secondary in order to arrive at conclusions of his own the reader is compelled to accept the results and conclusions arrived at, for there are no records given to examine to check the results obtained.

No indicator cards or valve settings are given, and neither is the method of measuring the gasoline consumed. No exhaust gas analyses have been reported. There is no conclusion or formula for the comparison of the performance of different cars in terms of gasoline used, transmission and gear ratios, wheel dimensions and car resistance.

Road tests were not made to determine the air resistance, but this was calculated from an assumed area. There is no statement as to the resistance of the air on the wheels when moving at speeds on the test bench corresponding to actual speeds on the road. The accelerometer which has proved its worth in road testing is not even mentioned, and thus Dr. Riedler failed to avail himself of one of the most valuable instruments for testing work.

Dr. Riedler compares the test results of two cars of widely varying types, a Renault touring car of 1905 with a high-powered racing car of modern construction, a Benz of 1910. Naturally the latter gave a better performance.

The effect of using different makes of tires is not touched upon nor is mention made of the condition of the tires, points of importance in discussing tire losses.

No account of carbureter efficiency or the effect of proper mixture is given.

Poor results were obtained in testing the Daimler-Knight motor, because the valves were improperly set, giving low power at high speeds; the carbureter was too small for the motor and lubrication was defective. For these reasons Dr. Riedler failed to obtain within 50 per cent. of the maximum horsepower possible with this motor as determined by Professor Morgan at the University of Bristol.

Some Criticisms Made

In the discussion Professor Riley of the Massachusetts Institute of Technology stated that in his opinion the tests were disorderly and that many mistakes had been made in translation. He also said that the proper basis of comparison for different types of motors was the mean effective pressure per square inch of piston area. He stated that good four-cycle designs of both the Knight and poppet type had given pressures as high as 110 pounds per square inch. He gave the following formula for calculating these pressures:

$$\text{Effective pressure} = \frac{\text{B. H. P.} \times 1008000}{D^2 \times S \times N \times P}$$

where D = bore, S = stroke in inches, R = the revolutions per minute and N = the number of cylinders.

He also said that if the specific pressure as calculated by this formula dropped below 70 pounds the valves were not properly set, and for high speed this figure should be at least 85. In the White and Poppe, for example, in 1,700 tests the pressure varied from 85 to 109 pounds.

Herbert Chase was of the opinion that for comparative purposes it was better not to drive through the tires because tires offer varying resistance, depending on the make and also upon the weight of fabric and the thickness of the tread. The amount of power that different tires will absorb will vary as much as 100 per cent.

Owen Thomas stated that the horsepower developed by the Daimler when tested by Professor Morgan at Bristol was 61.3, while the same model tested by Riedler showed an output of 41.3 horsepower. In the one case the horsepower per litre of cylinder volume was 16.3 and in the other 11.1.

Some of those present were of the opinion that laboratory testing was so different from actual road work that the results were not worth the expense, but Arthur B. Brown and Professor Lockwood of the Sheffield Scientific School stated that in the testing laboratory at Yale the tests in the laboratory agreed very closely with these on the road, and that the laboratory tests were of great advanage because of the possibility for accurate measurement.

At the next meeting of the section, which will be held on Tuesday, November 24, D. McCall White of the Cadillac company and designer of its eight-cylinder motor will discuss this type of engine.

AKRON, O., Nov. 3—The Swinehart Tire & Rubber Co. has declared a quarterly dividend of 1 1-2 per cent. payable January 15. The books close December 31.

S. A. E. Winter Meeting January 6-7

Professional Sessions on Both Days—Standards Committee Meets November 17-19

NEW YORK CITY, Nov. 2—The full program of the winter session of the Society of Automobile Engineers has been announced. Professional sessions are scheduled for the morning, afternoon and evening of January 6 and 7 in the Engineering Societies Building, 29 West 39th street. Plans are being made to have the members dine together informally on each of the meeting days.

The Standards Committee convention will be held November 17-19 in the rooms of the society at 1790 Broadway. The purpose of this meeting is to provide an opportunity to discuss the various standards and practices under consideration for recommendation, as well as some standards and practices that have been accepted heretofore. It is expected that reports will be made by several of the Standards Committee divisions. The subjects which will probably be touched upon are the following:

Stock sizes of roller bearings.	Non-glaring headlights.
Flanges for side outlet carbureters.	Wiring systems for motor cars.
	Scientific tests for engines.
Thickness of truck felloe bands.	Horsepower formula data.
Electric vehicle standards.	Pneumatic tire stock sizes.
Industrial truck standards.	Tap drill sizes.
Properties of S. A. E. steels.	Vehicle taxation formula.
Heat treatment of steels.	Leaf spring clips.
Steel casting specifications.	Bell housings for unit plants.
S. A. E. lock washer standards.	Motor support dimensions.

The council will hold a meeting at the time of the convention and meetings of about a dozen of the divisions and sub-committees of the Standards Committee will be held during the 3 days' convention. Members of the society who can attend are welcome at the Standards Committee meeting.

Weed Wins Another Final Injunction

DETROIT, MICH., Nov. 3—*Special Telegram*—Judge Tuttle in the United States District Court here has issued a perpetual injunction restraining Arthur S. and Milton H. Perry from doing business under the name of the Perry Chain & Grip Co., the Union Steel Screen Co. and the Motor Specialty Co. from making automobile tire chains and held that patent No. 723,299 was duly issued to Harry Parsons, March 24, 1903.

This is the final decision in the suit brought by the Weed Chain Tire Grip Co. and the Parsons Non-Skid Co., Ltd., and Harry D. Weed, who are allowed about $18,000 profits and interest made by the Perrys.

Poole Makes Report on European Conditions

DETROIT, MICH., Oct. 30—The first report concerning business conditions in Europe written by John L. Poole, European export manager of the Hupp Motor Car Co., since his return to Europe was received a few days ago and concerns the situation in the United Kingdom.

"In general," writes Mr. Poole, "business conditions have improved in the Kingdom, and I can see no reason why we should not do a fairly good business in the motor car line during the coming season, unless, of course, England itself is open to an invasion by some hostile nation.

"As the Olympia, the annual motor car show of England, will not be held this season, Whiting, Ltd., Hupmobile distributors for the British Isles, will hold a motor car exhibit of its own, and anticipate a visit at that time from the eighty odd dealers who are located throughout England, Scotland and Ireland.

Nine Papers for Chicago Road Congress

NEW YORK CITY, Nov. 2—The American Road Builders' Assn., this city, has received acceptances from a number of well-known highway officials and engineers, announcing their willingness to prepare the leading papers on various subjects to be presented at the American Good Roads Congress to be held in Chicago, December 14-18. The acceptances so far received and their subjects are as follows:

"Road Foundations: Concrete, Telford, Gravel, Etc.," L. A. Johnston, division engineer, Massachusetts Highway Commission.

"Organization of a State Highway Department," John N. Carlisle, Commissioner of Highways of the State of New York.

"Traffic: Present Tendencies, Probable Development, Regulation," A. W. Dean, chief engineer, Massachusetts Highway Commission.

"Machinery for Construction and Maintenance: State, Municipal, Contractors, Traction Haulage of Stone, Care of Machinery, Instructions to Engineer and Operator," T. R. Agg, professor of highway engineering, Iowa State College.

"Brick Roads and Streets," John Laylin, division engineer, State Highway Department of Ohio.

"Surfaces or Floors for Bridges," Clifford Older, bridge engineer, Illinois Highway Department.

"Bituminous Construction and Maintenance, Recent Practice," William D. Uhler, assistant engineer, Bureau of Highways, Philadelphia, Pa.

"Concrete Roads," H. J. Kuelling, County Highway Commissioner, Milwaukee County, Wisconsin.

"Street Paving in Small Cities," Thomas H. MacDonald, State Highway Engineer of Iowa.

Saxon Adds Light Delivery for $395

DETROIT, MICH., Nov. 2—The Saxon company has branched out into the commercial field by adding a delivery car of 400 pounds carrying capacity to its well-known two-passenger type and selling at the same figure of $395. This vehicle is mounted on the same chassis as the roadster, and with its light weight it should have a big field among the various lines of business requiring quick delivery of light packages.

With practically the same bonnet and control features, the main change is the placing of an open-box type of body back of the driver's seat, which body has about the same length front and back of the rear axle. The carrying space is 48 1-4 inches long and 38 inches wide, with the sides 45 inches high.

The Saxon chassis has a wheelbase of 96 inches, is carried on 28 by 3 tires, on wire wheels, has cantilever spring suspension and a 15-horsepower motor, 2 5-8 by 4.

This motor is a four-cylinder L-head with cylinders and crankcase cast in one piece. It operates through a two-bearing crankshaft of drop-forged steel. Helical timing gears housed at the front operate the camshaft which is also a drop-forging having integral cams. Cooling is by thermo-syphon, ignition by Atwater Kent distributer system, and lubrication by the vacuum-feed arrangement. In this the level of the lubricant is automatically maintained at the same height as the controlling feed standpipe.

The clutch is a five-plate disk type steel against Raybestos, while drive to the rear is through a shaft enclosed within a torsion tube, this shaft being fitted with a universal joint at the front end. The gearbox, affording two forward speeds, is mounted on the rear axle, being controlled by center lever. The rear axle is of the semi-floating type with a pressed-steel housing, the outer end of the drive shaft being carried on Hyatt roller bearing, while the two-pinion differential is of plain bearing construction.

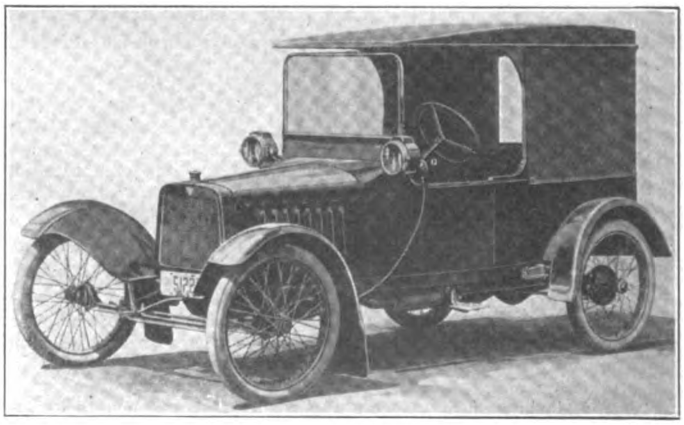
There are two sets of brakes on the rear wheels, the service set being 8 inches diameter Thermoid lined, while the emergency is steel on steel, 7 11-16 inches diameter.

The listed equipment is top and storm curtains, windshield, two gas headlights, oil rear lamps, gas generator and bulb horn.

The tread of the Saxon is standard 56 inches.

Gas-Electric Taxicab for N. Y. Taxicab Co.

NEW YORK CITY, Oct. 29—That the Mason-Seaman Transportation Co. will probably employ the combination of the gasoline engine and the electric motor in its taxicabs, is stated by W. H. Barnard of that company. Mr. Barnard states the company is at present experimenting with a new 1,000-pound cab which will be propelled by the above system, the invention of Mr. Rockwell, also of that company.



New Saxon light delivery car on standard chassis

National Shows Have 548 Exhibitors

118 Accessory Makers Take Space in Addition to Those Previously Announced

NEW YORK CITY, Oct. 30—Judging from the number of exhibitors who have been allotted space for the Fifteenth Annual National Automobile Shows to be held in New York and Chicago, it is evident that manufacturers of automobiles, motorcycles and accessories are preparing for the greatest year of business in the history of the industry. Announcement already has been made by Manager S. A. Miles, of the car exhibitors who will display their products at both shows, and the Motor and Accessory Manufacturers have announced the space allotted to their members. However, since those announcements were made 118 accessory makers and 13 motorcycle concerns have secured space for the national shows, bringing the total number of exhibitors for both exhibitions up to 548. The New York Show is to be held in the Grand Central Palace, January 2-9, and the Chicago show will be held in the Coliseum and First Regiment Armory from January 23 to 30. The complete list of accessory manufacturers exhibiting at both shows to date is given below:

Panama-Pacific West's First Big Show

SAN FRANCISCO, CAL., Oct. 28—The first show of any magnitude west of the Rockies covering the automobile industry will be held in the Palace of Transportation at the Panama-Pacific International Exposition the coming year. Nearly 40 per cent. of the space in the mammoth structure built to house the transportation exhibits is given over to the makers of pleasure cars and accessories. The available space has been heavily over-subscribed and the department has been compelled to utilize every available foot of space possible in an effort to accommodate the exhibitors.

There are several noteworthy features connected with the coming automobile exhibition. Divisions have marked the holding of a number of shows in the east in the past, the manufacturers and their dealers grouping themselves into associations and holding separate exhibitions. There are no such restrictions regarding exhibitors at the coming show, the gates being thrown open to any worthy exhibit.

The automobile section occupies nearly the entire eastern half of the building. Running along the north and south central aisle in the nave of the building is a façade of Italian pergola design and divides the section from the other portion of the building. There are domes over the entrances to the aisles in the section for a lattice-work effect

The accessory manufacturers and dealers are given space along the side walls of the section. The walls about and above their exhibits will be decorated by the exhibitors themselves.

The exhibits in the section will be many and varied. In addition to the usual display of finished types of cars will be shown cutaway chassis, cars in course of construction, assembling plants and the making of various parts. The exhibits are intended to have a distinct educational value.

The official headquarters for automobilists will be found in the offices of the California State Automobile Assn., located just to the east of the main entrance. A well-equipped information bureau will be maintained.

Boston Electric Show Opens with 10 Exhibits

BOSTON, MASS., Oct. 30—The Second Electric Automobile Salon under the auspices of the Electric Motor Car Club of Boston is being held in the Grand Ballroom of the Copley Plaza Hotel in Boston from Monday to Friday, November 2 to 6, inclusive.

It is not quite so crowded as last year's Salon for there are but seventeen vehicles exhibited while the first one had twenty-six. But it is a really representative exhibition, for all the various types made by the electric men are displayed. There is a good chance to note the tendency of some makers toward the streamline design of body; the five-passenger model, by widening the bodies and the wire wheel.

Special attention has been given this year to interesting a large number of prospective purchasers over a wide territory including Boston and the prominent cities and towns within a radius of 40 miles. A special list of prominent people has been prepared and invitation cards mailed to them. Over 16,000 cards have gone out in this way in addition to the large number mailed by the Boston representatives of electric automobile manufacturers to their prospects.

The exhibitors and the number of cars displayed are:

NAME OF CAR	NO.
Bailey	3
Buffalo & Babcock	1
Detroit Electric	5
Ohio	2
Rauch & Lang	3
Waverley	3

ACCESSORIES	TYPE
Edison Storage Battery Co.	Batteries
Electric Storage Battery Co.	Batteries
Philadelphia Storage Battery Co.	Batteries
Wagner Electric Mfg. Co.	Rotary Converters

WASHINGTON, D. C., Oct. 30—President Sturgis, of the American Institute of Architects, has appointed a committee, composed of E. C. Jensen, Chicago, W. T. Mills, Columbus, and Benjamin Hubbell, Cleveland, to act in an advisory capacity to the Lincoln Highway Assn.

The purpose is to insure uniformity in treatment of all the bridges, markers, stations and monuments.

LIST OF ADDITIONAL ACCESSORY EXHIBITORS AT NEW YORK AND CHICAGO SHOWS

Adams & Co., Henry T..........Chicago, Ill.
Ajax Trunk & Sample Case Co., New York, N. Y.
American Taximeter Co.....New York, N. Y.
Arnold, N. B..................Brooklyn, N. Y.

Weidely Motors for the Trade

Weidely Motor Co. Organized—Engine To Be Sold Separate or with Entz Electric Transmission

NEW YORK CITY, Nov. 2—The Weidely Motor Co., of this city, is being incorporated to build Weidely motors to be sold to the trade and also to be used in conjunction with the Entz electric transmission manufactured by the Entz Motor Corp., this city.

R. M. Owen, president of the Entz Motor Corp., which controls the patents for this electric transmission, has entered into an arrangement with H. O. Smith and George Weidely, recently of the Premier company, whereby the Weidely Motor Co. has been formed and will own and control the patents used in connection with this motor.

Arrangements have already been made with two large engine manufacturers in this country to build these motors for sale to the trade. In last week's issue of THE AUTOMOBILE it was stated that a contract had been made between Messrs. Owen, Weidely and Smith with the receiver of the Premier Motor Mfg. Co. whereby the patterns, etc., of the Weidely motor become the possession of the newly-organized Weidely Motor Co., and that the Premier Motor Mfg. Co. is given the privilege of using the Weidely motors. The Weidely motor will either be sold as a separate unit or those desiring can purchase it in connection with the Entz electric transmission, thereby giving complete motor and transmission in a single unit.

U. S. Rubber Earns Dividends

NEW YORK CITY, Oct. 31—Up to October 1, with September earnings partially estimated, the United States Rubber Co. earned its dividends with a considerable margin to spare. Estimate of earnings for October is not yet practicable and it is stated that the directors are not in a position to consider a continuation of the common dividend at a 6 per cent. rate. A dividend of 1 1-2 per cent. was declared on the common stock, payable November 1, so that there will be no further consideration of a dividend by the directors until the meeting early in January. Tire sales in September ran 35 per cent. behind the corresponding month a year ago. October will probably show approximately the same decline, as compared with 1913. While there was a 35 per cent. reduction in the value, the actual drop in the number of tires sold was considerably below the 35 per cent. figure. Tire prices a year ago were above those prevailing this Fall.

AKRON, O., Oct. 30—The B. F. Goodrich Co. has declared the regular quarterly dividend of 1 3-4 per cent. on the preferred stock, payable January 1 to stock of record December 21.

Detroit Starter Co. Organized

DETROIT, MICH., Oct. 30—The Detroit Starter Co. was organized recently and incorporated, the officers being J. W. Fitzgerald, president; F. J. Lamb, vice-president, and A. B. Porter, secretary-treasurer. Offices have been opened at 969 Jefferson avenue.

The concern is now marketing the new starter and lighting system, which is being manufactured for it on a mutual sharing arrangement by the Ross & Young Machine Co., whose present capacity is 200 starters a day.

Several of the local automobile manufacturing concerns are arranging for the adoption of the new starter on their 1915 models, and the Saxon Motor Co. recently announced that it will furnish this starter upon demand.

Tilikum Cyclecar Co. Formed in Seattle

SEATTLE, WASH., Oct. 30—The Tilikum Cyclecar Co., Seattle, has recently been incorporated and is headed by N. J. Veline, I. D. H. Adams and C. G. Benson. The car is unique in mechanical construction and body lines. The frame is fashioned after the Franklin wood frame, which reduces vibration and strain on mechanical parts. The tread is 42 inches. The seat accommodates two passengers side by side. The wheelbase is 84 inches, correctly proportioned with the tread. The motor is of the V type of 10 to 14 horsepower, air cooled. The transmission is by patented variable pulleys and belts which give the operator the choice of twelve distinct speeds, changing from any one to any other without disengaging the clutch. The car has been run from 40 to 60 miles on a gallon of gasoline.

AKRON, O., Oct. 29—Goodyear Tire & Rubber Co.'s salesman's conference was brought to a close October 31. Four hundred and fifty branch managers and salesmen were in attendance. The conference was preliminary to the launching of the company's 1915 campaign, and concludes a fiscal year in which the increase in the number of tires made and sold over 1913 was nearly 35 per cent. For 3 days the men from the selling field were the company's guests. They inspected the factory with its 2,000,000 square feet of floor space and watched the actual operations by which 7,500 workers turn out the Goodyear product. There were addresses, a banquet and other entertainment in the evenings, and the days were devoted to discussions of trade conditions.

Abner Doble Motor Vehicle Co. Incorporates

WILMINGTON, DEL., Oct. 30—The Abner Doble Motor Vehicle Co. has incorporated in this city with a capitalization of $500,000 to manufacture and deal in the Abner Doble steam automobile. The incorporators are G. W. Dillman, E. Price, M. M. Dugan, G. P. Postles and R. R. Whittingham.

A description of this car was published in THE AUTOMOBILE for April 9, 1914.

Shoemaker Resigns from A. A. A.

NEW YORK CITY, Oct. 30—T. B. Shoemaker, who for several years has served as secretary of the Contest Board of the American Automobile Association, has resigned. Chairman Kennerdell, has not as yet appointed a successor.

Splitdorf Alleges Bosch Infringes Patent

NEW YORK CITY, Nov. 2—The Splitdorf Electrical Co., Newark, N. J., has filed suit against the Bosch Magneto Co., New York City, alleging infringement of Patent No. 1,074,416, covering means in a magneto ignition system for changing the polarity of the armature to coincide with the polarity of an external current during the time that the primary winding on the armature is coupled with the external source of current. The object of this system is to use a battery and a coil in connection with the primary winding of the magneto to produce a sufficient current for ignition purposes for easy starting at low cranking speeds. This is commonly known as a duplex system.

Officials of the Bosch company state that they believe that Splitdorf's claims of infringement are not correct and that they will endeavor to prove this.

The patent in question was granted to John M. Dinkins, Franklin B. Hays and William L. Taylor, all of Indianapolis, Ind., September 30, 1913. Eight-fifteenths of the right, title and interests of the patent were transferred to William L. Taylor, and then by a written assignment dated July 10, 1914, the Splitdorf company became sole owner. This company alleges that the Bosch company has infringed since the date of the patent and since July 10, 1914.

The plaintiff prays for an injunction, as well provisional as permanent, and also that the defendant account for profits made by it and damages sustained by defendant, and that upon rendering of the decree the actual damages so assessed be tripled. The plaintiff also prays that the defendant defray the costs of the suit, and waives verification of the defendant's answer.

The suit is brought in the U. S. District Court for the Southern District of New York.

Denver Passes Anti-Glare Ordinance

DENVER, COL., Oct. 30—An ordinance designed to put an end to the dangerous glare of motor car and other vehicle headlights on Denver's streets has been passed by the city council and will go into effect tomorrow. An increasingly large number of serious accidents during the last year or more have been charged to the blinding glare of these unduly brilliant lights and a great deal of sentiment has developed in demand for a law to protect human life against this danger, In fact, many motorists themselves have declared the city behind the times because of its failure to remedy this deplorable feature of traffic conditions. The measure was urged and strongly backed by the Denver Motor Club, which has pledged the city officials its hearty co-operation toward enforcing the provisions for dimming lights.

The principal clauses of the new ordinance are:

It shall be unlawful for any person operating any automobile, motorcycle or other vehicle, upon the public streets and highways within the city and county of Denver, to use acetylene, electric or other bright headlight or any headlights, the rays from which are intensified by any condensing reflector, unless such headlight shall be properly shaded or adjusted so as not to blind, dazzle or confuse other users of the highway or make it difficult or unsafe for them to ride, drive or walk thereon.

Grossman Gets Injunction in Patent Suit

NEW YORK CITY, Nov. 2—Thomas F. Wilson and the Emil Grossman Mfg. Co., Inc., have been granted a perpetual injunction against Harry Weinstein, doing business under the trade names of Royal Auto Tire & Supply Co., Liberty Tire & Supply Co. and Union Tire Co. The plaintiffs alleged infringement of their patent No. 1,044,468 covering a form of thrust bearing by the defendant's "Radius rod anti-rattlers for Ford cars." The decree was issued with the consent of the defendant.

The plaintiffs prayed for a perpetual injunction, delivery to them for destruction of all infringing devices, triple damages and costs, but waived damages and costs when the defendant turned over to them the infringing devices.

The suit was brought in the U. S. District Court for the Southern District of New York. The Emil Grossmann Mfg. Co., Inc., owns one-tenth interest in the patent at issue, the remainder belonging to Thomas F. Wilson, the other plaintiff in the suit.

INDIANAPOLIS, IND., Nov. 2—A suit asking for the appointment of a receiver for the United Supply & Accessories Co., Indianapolis, has been brought in the circuit court in that city by S. C. Rennick, manager of the company. Mr. Rennick alleges the company is in danger of insolvency and has been unable to obtain sufficient capital with which to conduct a paying business.

To Protest Proposed Uniform Law

BOSTON, MASS., Oct. 29—A special meeting of the Massachusetts Automobile Operators' Assn. was held last week at which the proposed uniform motor law now being considered by the commissioners on uniform laws at Washington was discussed. James Fortesque, secretary of the Massachusetts State A. A. and J. T. Sullivan of the Boston *Globe* addressed the meeting pointing out that according to dispatches it was intended to put in a clause requiring drivers to wear badges, and another that convictions should be written on licenses. It was pointed out that there was a badge clause in the Bay State motor law, but because of persecution by police of drivers the legislature took it out. Also that attempts to put in a conviction license clause has been rejected by the legislature several times. President J. E. Connors was then empowered to call a special meeting of the legislative committee to frame a protest to send to the commission, and this will be passed at the next meeting.

Hard Test of N. J. Drivers

TRENTON, N. J., Oct. 29—To what a great extent automobiles are used in New Jersey is indicated by the statement of State Motor Vehicle Commissioner Lippincott today, that from January 1 last to October 1, the number of persons examined by the department for drivers' licenses was 21,901. Of this number 19,471 were passed and 2,430 were rejected, showing that approximately 11 per cent. were unable to qualify as drivers.

Standard Oil and Gulf Refining Indicted

NEW YORK CITY, Nov. 2—Despite the fact that the Standard Oil Co. was absolved in the Hudson county court in New Jersey when charged with violating one of the Seven Sisters anti-monopoly acts by price-cutting, it, and the Gulf Refining Co., have been indicted by the Hudson county grand jury; these are the first indictments to be found under the Seven Sisters acts passed under the governorship of Woodrow Wilson.

The county court held that the Gulf and not the Standard company was at fault; the evidence before the grand jury was that the Gulf company started to cut the price of gasoline in May; Standard met the cuts; the price fell from 22 to 11 cents. The Crew-Levick company alleged that its business had been damaged and it was alleged that it was the intent of the big companies to "freeze out" smaller competitors. Should the indictments result in convictions the defendants may lose their charters; trial is expected this month.

Exports for September Total $892,192

WASHINGTON, D. C., Nov. 2—Figures issued today by the Federal Bureau of Statistics show that during September, 128 commercial cars, valued at $294,288, and 646 passenger cars, valued at $597,904, were shipped abroad. During the 9 months ending September the number of commercial cars exported was 637, the value being $1,066,545, while the passenger car exports amounted to 19,530, valued at $17,209,964.

Drawback Granted on Exported Cars and Parts

WASHINGTON, D. C., Nov. 2—A series of orders has been issued by the Treasury Department instructing collectors of customs in various cities to allow, under paragraph O, section 4 of the tariff act of 1913, drawback on the exportation of various articles, as follows: Automobiles: Packard, Baker electric, Chandler and Abbott; automobile axles, Hess Spring & Axle Co., Yuster Axle Co., for account of Chandler Motor Car Co., American Ball Bearing Co.; aluminum hoods, Michigan Stamping Co.; windshields, Universal Windshield Co.

NEW YORK CITY, Oct. 29—At the annual meeting of the J. S. Bretz Co. yesterday, the retiring directors and officers were re-elected. They are as follows: J. S. Bretz, president; Jack L. Straub, secretary and treasurer, and the directors are: J. S. Bretz, J. L. Straub, R. W. Leslie, John Hertzler and C. G. Tuthill.

BROOKLYN, N. Y., Nov. 3—The Brooklyn Garage Owners' Board of Trade has arranged through a coal committee to purchase coal and coke for members for the coming winter. At a meeting held Monday evening, November 2, this committee compiled a list of garagemen who will take a total of 800 tons. The association members are enthusiastic at the work the organization is accomplishing. At its inception it secured a brand of gasoline and oil on which it placed its stamp, and now is having manufactured by a well-known tire company a tube which is put out under the name of Board of Trade tube. Several new members were added at Monday's meeting.

Market Reports for the Week

No changes of any importance occurred in this week's market reports. The metal products were held more firmly and the oils and lubricants saw some quiet trading. A stronger tone in tin was developed at the end of the week, that product closing at a gain of $1.50 per 100 pounds. Lead was quiet and steady at $3.50 per 100 pounds. Antimony is quiet, but strong and prices are nominal. The crude rubber market was quiet. Trading conditions were dull, but the market had a firmer tone owing to the action of Turkey in entering the European war. It is feared that this may result in the closing of the Suez Canal and greatly interfere with shipments of rubber from the East. Up-river Para remained unchanged for the week at $0.66.

DePalma Wins Four at Brighton

Five Races Altogether—10 Mile Handicap Won by Chevrolet

NEW YORK CITY, Nov. 3—Ralph DePalma and his Grand Prix Mercedes starred at Brighton Beach race track today, taking four out of the five events and capturing $650 in prize money. The other race, a handicap, was won by LeCain in a Chevrolet. Jessup, also driving a Chevrolet, was second in this race, while DePalma took third honors.

The first event was non-stock, limited to cars with less than 300 inches piston displacement. The distance was 10 miles and Ralph easily drew away from the rest of the field, winning in 9 minutes 53 2-5 seconds. Morton, in a Mercer, was second and LeCain in a Chevrolet, third.

Event number two, for 10 miles for non-stock cars under 450 cubic inches, was won by DePalma who covered the distance in 9 minutes 34 seconds. Second went to John DePalma in Ralph's old six-cylinder Mercedes, and third was won by Morton, in the Mercer.

The third race was a non-stock free-for-all for 10 miles and was likewise taken by DePalma in 9:21 4-5. John DePalma was second and Morton, in the Mercer, third.

Next was the handicap and this proved the most interesting and exciting. LeCain's Chevrolet won, with his teammate Jessup at his heels. DePalma was third, his handicap being too large as he was the only one started from scratch, about a mile in the rear. The time was 9:53.

The fifth race was originally intended to be a 50-mile contest but it was shortened to 40 miles because of darkness. It was won by DePalma, with Morton and the Mercer second and LeCain and the Chevrolet third. The time was 37 minutes 27 2-5 seconds. The little Mercer has a Fritz carbureter.

Greeks Give Out Truck Specifications

NEW YORK CITY, Nov. 4—Specifications for the 400 additional motor trucks for the Greek army, to supplement the fifty KisselKar vehicles recently purchased have been given out. These cover 1 1-2-ton chassis of standard construction, shaft-driven, with uniform tire sizes front and rear, four-speed gearboxes, good clearance, fairly high speeds, and equipped with service bodies. Among the peculiar requirements are stiff, heavy springs of little flexibility, double-jet carbureters, demountable rims, driving shaft brakes, and auxiliary water tanks under the driver's seat. The specifications follow:

Frame—Pressed steel, simple and strong.

Motor—Flexible; monoblock, 3½ by 5½, with compression release and governor set at 30 miles per hour.

Differential—Light, of dimensions as constrained as possible, and capable of resisting most violent brake strains.

Carbureter—Latest type, with double jets.

Magneto—High-tension.

Front whels—Detachable rims, 35 by 5 tires.

Rear wheels—Strong; demountable rims, 35 by 5 tires.

Drive—Cardan shaft, with two universals preferred.

Springs—Front and rear very strong with lititle flexibility.

Maximum load—3,306 pounds.

Steering—Practically irreversible, all movable parts with grease cups, and all parts very strong.

Clutch—Smooth-acting, metallic preferred.

Gearset—Strong, with four speeds forward and one reverse; selective type preferred.

Brakes—Two sets; one back of gearbox preferred; handbrake on both rear wheels.

Gasoline tank—At rear, pressure fed, holding 25 gallons; strongly secured to chassis and placed as high as possible, 20 inches from ground.

Water tank—Under driver's seat; capacity 8 gallons at least, with a cock at the outside of body.

Radiator—Of sufficiently large surface to avoid boiling of water even under the highest temperature of 104 degrees Fahrenheit in the shade; should be mounted on a shock-absorber and should have a drain cock.

Fan—Flywheel fan preferred, or else two fans.

Clearance—11.8 inches.

Lubrication—Constant-level splash-pressure system.

Speed—The truck must attain a speed of 27.9 miles per hour on the level with full load.

Body—Light and strong, of careful construction, with 43 square feet of floor-area, and with tailboard to fold down on hinges to form steps; equipped with top.

Seats—For two, driver's seat roomy and low, with an abundance of leg-room.

Cab—Must have top of folding type, which is substantial when folded.

Windshield—Solid, but folding outward; constructed to permit easy replacement of glass.

Tools—Each truck must have a kit of tools in a tool box well located in the body.

Spare parts—Complete set of most needed spare parts.

Fast Time at San Antonio Track

SAN ANTONIO, TEX., Oct. 31—Fast time, clever driving and close finishes featured the opening of the San Antonio Automobile Club's automobile races at the Fair Grounds track this afternoon. The day was ideal and a good mid-week crowd saw the events.

The following are the results of the first day's events:

Class E, 3 Miles

CAR	DRIVER	TIME
Ford	Hoffman	4:20
Buick	Meleun	
Studebaker	Johnson	

Class E, 600 Cu. In.—9 Miles

CAR	DRIVER	TIME
Simplex Zip.	Disbrow	9:10 4/5
Case Special	Ulbricht	
Braender Bull Dog	Chandler	

Class E, 300 Cu. In.—6 Miles

CAR	DRIVER	TIME
Scat	Cleary	6:05
Mercer	Milton	
Ford	Hoffman	

Team Novelty Relay Race

CAR	DRIVER	TIME
Case	Hearne	4:34
Braender Bull Dog	Chandler	
Simplex	Disbrow	
Case Special	Ulbricht	

Class D, Free for All—9 Miles

FIRST HEAT

CAR	DRIVER	TIME
Case	Hearne	8:56 4/5
Simplex	Disbrow	

SECOND HEAT

CAR	DRIVER	TIME
Case	Ulbricht	9:15
Mercer	Milton	

HANDICAP—4 MILES

CAR	DRIVER	TIME
Simplex	Disbrow (Scratch)	3:36
Ford Special	Hoffman	

A. A. A. Gives Sanction for Indianapolis 500 Mile Race

INDIANAPOLIS, IND., Oct. 31—Official sanction has been obtained by the Indianapolis motor speedway from the American Automobile Assn. for its next 500-mile race, thereby refuting recent reports to the effect that the owners of the Hoosier track contemplated breaking with the parent organization. Speedway officials assert that they are on the friendliest terms with the A. A. A. and have no thought of taking independent action.

The recent announcement by the track management that it would in the future supervise manufacturers' tests on its own responsibility, is declared well founded on precedent, similar trials having been conducted under the auspices of the Chicago Automobile Club, without A. A. A. sanction; nor, it is said, is there any animus manifested toward the A. A. A. by the speedway in taking such action. Everything points toward a most successful contest season in 1915, it is stated, so that to stir up a row at this time would be considered wholly unwise.

Race Track Planned for Omaha

OMAHA, NEB., Oct. 30—An automobile race track 2 miles in length and pitched at an angle varying from 10 to 42½ degrees will be erected in Omaha soon. It is planned by the builder, Jack Prince, to have it in readiness by November 25, Thanksgiving day, and to have Barney Oldfield, Bob Burnham and Louis Disbrow as the opening attraction. It will cost approximately $150,000.

The automobile speedway is to be located near the present motorcycle speedway. In connection with the two speedways there will also be an aviation field. The first big racing meets will not be held until next spring.

Brad-Kent-Equipped Ford Does 33 M.P.G.

CHICAGO, ILL., Oct. 29—To demonstrate the fuel economy of the Brad-Kent carbureter, made by the Frost Mfg. Co., of Kenosha, Wis., a run from Chicago to Milwaukee was made on October 23, under the direction of F. E. Edwards, chairman of the technical committee of the Chicago Automobile Club, which resulted in the average of 33.12 miles to the gallon being made in a 1913 model T Ford.

It was a cross-country run of 102.1 miles and conditions were not at all favorable, there being a 25-mile-an-hour head wind to buck, while the roads were rough in many places. Also the car was held up several times in the traffic of the cities through which it passed. The thermometer varied from 50 in the morning to 59 in the afternoon.

The weight of the car with passengers was 2,050 pounds and the gasoline was of 63 degrees at 60 degrees Fahrenheit. The exact fuel consumption was 3 gallons 10.5 ounces. It took 4 hours 28 minutes to make the run.

2-Mile Saucer for Twin-City Races

To Cost $1,250,000—80 Feet Wide—2,200 Foot Banked Curves

MINNEAPOLIS, MINN., Oct. 30—The Twin-Cities are to have one of the greatest motor speedways in the world, according to the plan of organization adopted at a special meeting in this city tonight when the Twin-City Speedway Association was started with a capital stock of $1,000,000, of which $350,000 in common stock was taken by F. H. Wheeler, Indianapolis, Ind., one of the four to finance the present Indianapolis speedway. The remainder of the stock was taken by Twin-City interests before the close of the meeting.

The new speedway is to be entirely a Twin-City affair and will be a 2-mile platter-shaped track 80 feet wide, and having on either side gravel safety zones 32 feet wide. The track will be banked throughout its entire circuit, the banking being 2 per cent. on the straightaways and 35 per cent. on the turns. The radius of the curves will be 2,200 feet. It will be 4.5 miles from the court house in either St. Paul or Minneapolis.

The present plans are to have a 300-mile race on Labor Day next year, which will be the only meet of the season. The motor sizes for this race have not as yet been announced nor have the prizes.

The organization, which will handle this new $1,250,000 speedway, for this is what it is expected to cost, is headed by F. H. Wheeler, president; Henry Habighorst of St. Paul, and J. D. Hogan, Minneapolis, as vice-presidents; Dr. C. E. Dutton, secretary; W. D. Hogan, treasurer, and directors, O. Kellogg, J. F. Sperry, and Judge Frank McNulty, of Aberdeen, S. Dakota. With the exception of Judge McNulty and Mr. Wheeler, all of the officers are Minneapolis and St. Paul business men.

Financing Scheme

In the organization there is to be an issue of $750,000 bonds bearing 8 per cent. interest, which may be retired at interest-paying dates at 3 per cent. per annum. The Van Sant Investment Co., of St. Paul has been made fiscal agent.

The new speedway is to be located in a section known as Longchamp Park. It is bounded by Snelling, Hamlin and Crosley avenues and Larpenteur Road, all boulevards leading direct from the cities. It is within reach of the Twin-City street car lines, which will be extended to take care of the grounds, and close to all the railroad lines that enter St. Paul and Minneapolis. Transportation facilities by street car, train, motor car and on foot are unexcelled.

Seats for 106,000

Plans have been drawn by Walter D. MacLeith of St. Paul, and some of the contracts will be let within a month. It is estimated that the grandstands will seat 76,450 persons and the bleachers an additional 30,000. There will be accommodations within the grounds for 100,000 motor cars.

The buildings within the oval of the track will be sunk so as not to interfere with a view of people sitting in the parked motor cars. The track itself will be below the level so that the grandstand, beginning level with the ground at the upper edge of the speedway will furnish a view to all people, whether in the boxes at the ground level, or at the top. The general type of the buildings will be progressive Spanish, in plain lines and finished in overcast stucco. Opposite the grandstand will be forty pits. The judges' stand will be four stories, accommodating 300 officials, 300 press and telegraph men, with over capacity of 100 more.

The equipment of buildings includes, beside the grandstand and bleachers, a hospital, two round house garages, power plant, twenty-two toilets, four towers in the fence, and judge and press stand to accommodate 700, connected with the grandstand opposite by a suspension bridge at the start line, and bandstand for 300 pieces. On the ground floor rear will be the entrances, with subway for motor car delivery and bridges for pedestrians to enter. On the second floor will be an automobile exhibition room, 56 by 3,225 feet, with posts only every 50 feet. Seats will be of wood. In the 1,625 boxes will be six large arm chairs each with table for service from the seven restaurants. The third story will be for storage. The hospital will be 40 by 60 feet with an operating room 12 by 18 feet and room for physicians and nurses.

In building the track, the base will be 12 inches of rolled trap rock, and the facing 6 inches of concrete laid in two layers of 3 inches each. Each side of the track is to be a 2 1-2-foot concrete breast wall topped with a 10-foot fence of 12-gauge wire to keep tires from being thrown out of the track. Ninety thousand yards of trap rock will be needed for the bed work. Four miles of fence 8 feet high will surround the entire grounds. This fence will be pierced by three gateways admitting twelve people per second. There will also be three automobile entrances capable of admitting six automobiles abreast every second.

The possibilities of attendance at this speedway become real when it is remembered that there is a population of 850,000 within a radius of 50 miles. To this can be added the vast Northwestern territory one of the richest agricultural sections in the country and a section which has been one of the greatest buyers of motor cars.

Overland's October Business Totals $5,572,000

TOLEDO, O., Nov. 3—October was the biggest month's business in the history of the Willys-Overland Co., which shipped 5,601 cars valued at $3,572,000. This was an increase of 15 per cent. over the same month's sales in 1914.

Since January 1, 11,368 more cars have been shipped than to the same date last year. The company has 18 per cent. more unfilled orders now than for the same time last year.

At the annual meeting of the stockholders of the company, October 26, all the officers and directors were re-elected. John N. Willys again heads both The Willys-Overland and Garford companies, with Isaac Kinsey as first vice-president; C. S. Jameson, second vice-president; R. R. Scott, secretary; Walter Stewart, treasurer; W. E. Tigges, comptroller, and E. L. Clapp, assistant treasurer, of the Willys-Overland Co., and C. S. Jameson, vice-president; R. R. Scott, secretary; and Walter Stewart, treasurer of the Garford Co.

The board of directors of the Willys-Overland Co. consists of John N. Willys, Isaac Kinsey, C. S. Jameson, R. R. Scott, Walter Stewart, H. L. Shepler and Rathbun Fuller, all of Toledo. The directorate of the Garford Co. is the same, except that H. L. Hooke's name appears in place of that of Rathbun Fuller.

H. L. Hooke was appointed manager of the Willys-Overland plant in Toledo and J. H. Gerkins was reappointed cashier and E. E. Weiss, assistant cashier.

Eisemann Adds Space—Works Double Shift

NEW YORK CITY, Nov. 4—The Eisemann Magneto Co., Brooklyn, N. Y., has found it necessary to add 15,000 square feet of manufacturing space to its factory, and to also work a double shift. This double shift has been in operation for 3 weeks, while previous to that the force was working 3 hours per day overtime. The company expects this overtime work to continue for the next 5 or 6 months.

Custodian Appointed for Havers Company

DETROIT, MICH., Nov. 3—*Special Telegram*—Judge Tuttle in the United States District Court yesterday appointed Lee E. Joslyn Referee in Bankruptcy as custodian of Havers Motor Car Co., Port Huron, Mich. Three creditors claiming an aggregate of $20,595 due merchandise, petitioned the court to have the company adjudged bankrupt.

Fifth Avenue Coach Co. Earns $226,673

NEW YORK CITY, Nov. 3—The Fifth Avenue Coach Co., this year increased its net earnings $62,217 over last year, the income from operations amounting to $226,673. The total revenue amounted to $1,176,650.

The report of the company for the year ended June 30 last, compares as follows:

	1914.	Increase.
Total revenue	$1,176,650	$240,982
Total expenses and taxes	949,977	178,765
Income from operation	$226,673	$62,217
Other income	4,472	1,721
Gross income	$231,145	$63,938
Deductions	40,708	3,853
Net income	$190,437	$60,085
Profit and loss adjustment debit	10,175	10,744
Surplus	$180,262	$49,341

PREPARING Chevrolet's Tarrytown Plant—Machinery is rapidly being installed in the new plant of the Chevrolet Motor Co. at Tarrytown, N. Y. This group of buildings, which comprised the old Maxwell factory, is the third Chevrolet factory. The main one is in Flint, Mich., and there is one in the heart of New York City. It is stated that the Tarrytown plant will be capable of turning out 10,000 cars per year when equipment is complete, while the New York City factory can produce 6,000 machines, under pressure. The plant at Tarrytown consists of two large, long buildings. The main one is approximately 750 feet long, 60 feet wide and three stories high throughout nearly its whole length. Paralleling this building is a one-story structure. A unique plan of production has been adopted by the company. Instead of concentrating the production in one central factory in the Middle West, it believes in locating assembling plants near points of great demand, such as New York City. Therefore, in these two Eastern plants the cars are completely assembled from parts received from the main factory in Flint and from certain parts and accessory makers. The city factory takes care of local customers and most of the shipments from this factory are made on the wheel while the Tarrytown factory is for the other parts of the territory, which embraces New England, New York State, eastern Pennsylvania and the States South bordering on the Atlantic. The advantages of these sub-factories, it is claimed that freight charges are reduced both on parts and on finished product. The factory being located close to the dealer, can give the latter individual attention and better service, and as there are comparatively few dealers, the members of this factory organization soon get to know all the dealers personally, and can, therefore, help them in marketing the product. The dealers, on the other hand, being in such close touch with the factory, can often give valuable suggestions to the manufacturer.

Auto Products to Add—The Auto Products Co., Canal Dover, O., has plans for a one-story reinforced concrete, brick and steel factory building, to be built at a cost of $15,000.

Lamp Plant in Los Angeles—J. P. Sherriffs will build a factory at 117 36th Place, Los Angeles, Cal., for the manufacture of automobile lamps. The building will be 50 by 124 feet in size, and will cost about $10,000.

Visit Canadian Factories—A large deputation from the French School of Commerce of McGill University, Montreal, Que., to the number of about thirty have recently been visiting the various manufacturing plants of the city.

New Ford Plant in Canada—A new factory is being erected at a cost of $300,000 for the Ford Motor Car Co., of Ford, Ontario, Canada. The building is to be six stories high, 200 by 195 feet in dimensions, of steel and reinforced concrete construction.

Victoria Plant in New Hands—The Auto-Rebuilding Co., Pembroke and Douglas streets, Victorial, B. C., manufacturer of automobile bodies, wheels, springs, engines, etc., has been taken over by a local syndicate with increased powers and larger working capital. The output of the plant will be increased.

New Plant for Shaw Motor—The Shaw Motor Co., Chicago, Ill., has decided upon the city of Prairie du Lac, Wis., for the location of its new plant. The plans call for a brick and concrete shop building, 60 by 108 feet, one story, with a saw-tooth roof, equipped for the production of gasoline engines. The investment on the new plant will be approximately $35,000.

Hoover to Manufacture Balls—The Hoover Steel Ball Co., Ann Arbor, Mich., which has been importing from Germany steel balls to the amount of $200,000 to $300,000 annually, has decided to manufacture a line of fine balls inasmuch as their importation from Germany has been stopped by the war. This year the stockholders of the company are receiving a dividend of 8 per cent.

New Ford Tire Co.—The Toledo-Ford Tire Co. will locate in Findlay, O., and expects to begin operations about the first of the year. The company will be capitalized at $300,000 and sell tires direct to the user. The Findlay factory will make tires in two sizes only and specialize on Ford automobile tires, reducing the cost very materially. They will sell, it is announced, 25 per cent. below the ordinary cost and save to the user about $19 per set.

Sparks-Withington Reports Good Business—"Business has never been better and the general outlook as bright," said President Sparks, of the Sparks-Withington Co., Jackson, Mich. "We have sufficient orders on hand now to keep us busy at least 90 days by working our entire force of 300 men at from 14 to 24 hours a day. Of course, the men do not work that many hours at one time, but per day and night shifts. Our home trade is excellent, but our foreign business is no less satisfactory, especially the business coming from Europe. A few days ago we received a cable order for 240 horns from Sweden and also a shipment went forward to Finland."

The Week in the Industry

Motor Men in New Roles

RECENT Changes in Indianapolis—Several changes have taken place in Indianapolis, Ind., trade circles. W. A. Roby, president, has bought the interest of his associate, H. L. Krieger, in the Electric Vehicle Service Station Co. W. W. Bond has been named by the Anderson Electric Car Co., Detroit, as district sales manager for the states of Indiana and Kentucky. L. C. Malott has been appointed manager of the William Small Co., distributors of the Chevrolet. D. B. Webster, formerly experimental engineer for the Hudson Motor Car Co., Detroit, has become assistant mechanical engineer for the National Motor Vehicle Co.

Downes Heads Locomobile Branch—F. H. Downes has taken charge of the new factory branch of the Locomobile Co., Portland, Ore.

Jones Resigns—W. G. Jones, until recently in charge of the service department of the Whitten-Gilmore Co., former Chalmers agent in Boston, has resigned.

Banta Sales Manager—H. A. Banta, who for some years past has been connected with Chanclor & Lyons Co., has joined forces with the Swan Carburetor Co., of San Francisco, Cal., in the capacity of sales manager.

Fickling Resigns—W. Irvine Fickling, for the past 4 years sales manager of the R. & L. Co., New York City, Eastern distributors of Garford trucks, has resigned and will shortly make an announcement of a new connection.

Adams Makes a Change—Al Adams, for 5 years manager of the used car department of the Joseph Donovan Co. in Boston, resigned last week to accept a similar position with the Auto Sales Co., on Worcester street, that city.

Bourne Double Fabric Manager—L. M. Bourne, for the past 6 years assistant production manager of the Goodyear Tire & Rubber Co., Akron, O., has been appointed factory manager for the Double Fabric Tire Co., Auburn, Ind. Mr. Bourne is an expert on rubber, and was in charge of the laboratories of the experimental department at the Goodyear plant.

Hayes Joins Pilot—E. O. Hayes, well known in the automobile trade through his former connection with the Midland, Velie and Imperial companies, is now traveling representative of the Pilot Car Sales Co., Richmond, Ind., in New England and New York.

Figman Indiana Truck Sales Manager—A. Figman, after 6 years' service with the Garford Co., New York City, has resigned to accept the office of sales manager of the Indiana Truck Co., Marion, Ind., with offices and service building at 250 West 54th street, New York City.

Fisher Chandler Branch Manager—John T. Fisher, well known formerly as a champion bicycle rider and later as an automobile driver, has been put in charge of the Chandler sales by the Northwestern Automobile Co., distributor in Minneapolis. Mr. Fisher has for three years been in charge of the Oldsmobile factory branch in Minneapolis.

Mass. State A. A. Election—The annual meeting of the Massachusetts State A. A. was held at Boston last week and President L. R. Spear, Vice-President John Coghlin and Secretary-Treasurer James Fortesque were unanimously re-elected. Reports were read by G. W. McNear, chairman of the legislative committee, and W. H. Chase of the good roads committee.

New Place for Gormley—G. B. Jeffery has resigned as advertising manager of the New England branch of the Firestone Tire & Rubber Co. at Boston, and he has been succeeded by C. J. Gormley.

Garage and Dealers' Field

Change in Paige—The Paige is no longer handled in Boston by the Nettleton-Crittenden Co. That firm also handles the Chandler and it decided to devote all its time to that make. So a new company has been formed by Sherwood Hall, Jr., formerly with the Cadillac and Hudson agencies, to handle the Paige, and he has leased the salesrooms formerly occupied by the Studebaker retail agency at 889 Boylston street.

Distinct Branch Now—The J. I. Case T. M. Co. has made the Boston branch of the company a distinct branch, taking it away from under the jurisdiction of the New York branch and placing it in charge of J. J. Gormley, formerly manager of the Lozier in that city. It will control the New England territory.

$120,000 in Sales in Winnipeg—A general feeling of optimism is noticeable in Winnipeg motor circles by reason of the big demand for new cars at the late date. The sale of new cars by Winnipeg dealers has reached a total of over $120,000 during the month of October. Many of the sales have been made to farmers.

Franklin Gets Out New Paper—The Franklin Automobile Co., Syracuse, N. Y., has come out with its first edition of the "National Cooling Record." The first edition is 100,000. The paper shows some interesting scenes along the routes of the recent low-gear tests of that company and also some scenes of historical interest, showing Franklin No. 1, built in 1902.

Houpt and Studebaker Exchange Places—The Studebaker Corp., New York City, has leased the five-story building, northwest corner of Broadway and 56th street, covering a 50 by 120-foot plot, for a service salesroom, at an aggregate rental of $300,000. This building was formerly occupied by Harry S. Houpt, who has now taken the former Studebaker building at Broadway and 59th street.

Maxwell's Omaha Service Station—The Maxwell Motor Sales Corp., of Detroit, has leased a building on Ninth and Jones streets, Omaha, Neb., where they will open up a branch service station. Charles Gould, of Detroit, manager of the service, has been in Omaha during the week arranging the deal. Omaha will be service headquarters for a large territory, comprising the states of Nebraska, Wyoming, South Dakota, Colorado, Idaho and a part of the state of Iowa.

Accessories for the Automobilist

HARTFORD Economizer—A 35 per cent. saving in fuel is guaranteed to Ford owners by the use of the economizer announced by the Hartford Suspension Co., 172 Bay street, Jersey City, N. J. A decided increase in power is also claimed. This new device, shown in Fig. 3, supplies superheated air to the mixture as it comes from the carbureter. The hot air is introduced through a flange fitting which has a series of radial openings around its circumference so that the hot air issues into the intake passage in small jets. The effect of this, it is said, is not only to heat the mixture but also to break it up and mix it thoroughly, thus making the mixture perfectly homogeneous. In other words, vaporization is aided in two ways, the heat turns any small particles of liquid gasoline into vapor while the mechanical action of the hot jets of air, impinging upon the mixture rushing through, churns the mixture up and makes it uniform.

The air is heated by passing it through a stove which is clamped to the exhaust pipe, as illustrated. The intake to the stove is at the lower left corner, and from here the air passes back and forth two and one-half times before it issues from the pipe which leads to the intake. The total length of the path through the stove is about 2 feet, and therefore it is seen that the air is well heated.

According to the company, mileage tests on a Ford car with an ordinary carbureter adjustment show that without the economizer the average mileage per gallon at speeds averaging 20 to 25 miles per hour is 20.1, and with the economizer attached, but all other conditions left the same, the mileage per gallon registers 27.7, a gain of 37.8 per cent.

There is a valve controlled by a lever from beneath the steering wheel which regulates the amount of hot air, and it is claimed that with the economizer valve wide open and the throttle closed the maximum speed of the car is around 25 miles per hour, and that up to this speed the car should be operated entirely by the lever controlling the economizer, the throttle being closed.

The attachment of the economizer is a simple matter. Outside of a hole which must be punched in the pressed-steel fitting holding the steering column to the dash and bored through the dash, there is no work that cannot be done with a wrench.

First, the carbureter is removed and the economizer flange slipped in place with a gasket on either side. Then the long control lever is bolted to the steering column at the top, and at the bottom it slips over the steering-wheel shaft and the spark and throttle rods. From this point an adjustable rod connects with the valve on the economizer.

The price of the complete outfit is $10.

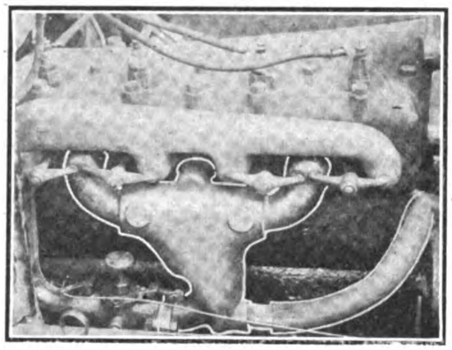

Fig. 1—Ford water-jacketed manifold

Spranger Wire Wheel with Demountable Rim—The feature of the wire wheel just announced by the Spranger Rim and Wheel Co., 705 Ford Bldg., Detroit, Mich., is that the rim is demountable and that any make of quick detachable rims may be used in connection with it.

The rim, Fig. 2, may be removed by loosening three bolts and no tool outside of any ordinary wrench is required to accomplish this. The rim is held in place by three sets of wedges, each operated by the bolts mentioned. As will be noted in the illustration, there are two metal blocks attached to the rim and when the rim is placed in the felloe, tightening the three screws draws up the wedge A which forces out the two arms B tightly against the two projections on the rim.

A further advantage of the new wheel, it is claimed, is that there is an air space between the felloe and rim which assists materially in carrying the heat off from the tires. It is also stated that the new construction is several pounds lighter and that it is necessary for the owner to carry a spare rim only instead of a complete extra wheel.

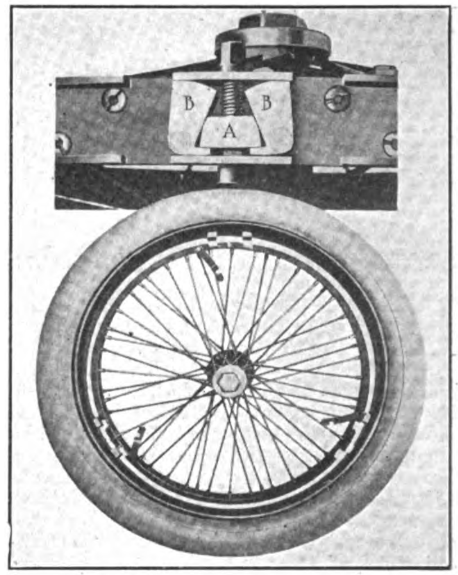

Fig. 2—Spranger wire wheel with demountable rim

Ford Water-Jacketed Manifold—Many advantages are claimed for the water-jacketed intake, Fig. 1, made by the Motor Devices Co., Mansfield, O., for Ford cars. According to the maker it not only gives a fuel saving of from 20 to 30 per cent., depending on the carbureter, but also gives increased power, speed and flexibility.

Gray & Davis Ford System.—A complete starting and lighting system for Ford cars, Fig. 4, has been brought out by Gray & Davis, Boston, Mass. Starting motor and lighting generator are distinct units, but they are compactly mounted in one casing, the motor being placed above the dynamo. In addition to these units a 6-volt battery, wiring, all the necessary connections and switches are included in the outfit.

Both units are connected to the crankshaft by means of silent chains. The motor is started by pressing a pedal and the lights are controlled by a switch

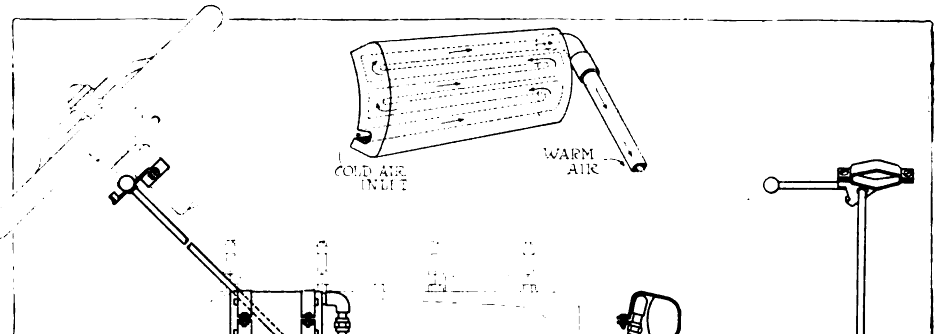

Fig. 3—Hartford economizer for Ford cars. Jets of hot air are drawn into the manifold. A 35 per cent. saving of fuel is guaranteed

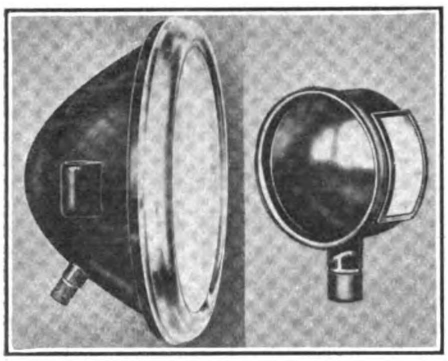

Fig. 5—Left—Gray & Davis Ford headlight. Right—Ford tail light

within easy reach on the dash. It is stated that the only attention required is occasional lubrication and addition of distilled water to the battery every 2 weeks.

To go with this new system this company is manufacturing electric head and tail lamps. These are shown in Fig. 5.

Thor Electric Drills—Four types of electric drills adapted for automobile repair work are manufactured by the Independent Pneumatic Tool Co., Chicago, Ill., under the name of Thor. These vary in capacity from 0 to 1-4, 0 to 5-16, 0 to 3-8 and 1-8 to 9-16 inches. The first is adapted for sheet metal work, drilling holes in frames, fenders and boring in wood up to 3-8 inch in diameter. The second size is used for the same work as the first, but it has a greater capacity. The third size is especially adapted for automobile body work, while the fourth, Fig. 6, is for general use in garages.

Ball bearings are used on the armature shaft and roller bearings on the spindle. The pinion on the armature shaft is removable. An improved type of switch is fitted, and the brushes are accessible. Any of these drills may be had for a 10-day free trial.

Compton Air Starter—An air-starter system, Fig. 7, is being put forth by the American Motor Utilities Co., New York City, which is featured by an automatic control which may be used in connection with any air pump maintaining the pressure at any predetermined point.

The starter unit is an air motor which has no dead center. It is stated that it develops a constant shaft torque of 3,200 inch pounds when operating under 100 pounds pressure.

Special care has been taken in designing the valves so that they will hold the pressure. All valves are brass seated when either open or closed, thus obviating stuffing boxes which may leak. All joints are ground brass unions attached to flaring ends of copper tubing, eliminating brazing and soldering.

The system is adaptable to big and little cars. The starter is installed at the side of the engine underneath the hood. Through the hollow starter shaft a smaller diameter shaft extends, from a sprocket wheel at the driven end, connected by silent chain drive to engine shaft, to a clutch at the driving end, which is brought into engagement with pump shaft and disengaged instantly and automatically as the air pressure falls below or is increased to predetermined points, respectively.

A pneumatically-operated roller bearing thrust clutch, provided with back-fire release, engages the air starter with shaft, driving or rotating the engine shaft the instant the starting valve is pushed downward. When explosions take up the propulsion the starter clutch is automatically thrown out of engagement, the sleeve shaft of starter remaining idle until the operation is repeated to again start the motor. The smaller shaft, passing through but not touching the sleeve shaft of starter, is brought into engagement with the pump shaft by the automatic control and restores the air pressure in storage tank to its maximum again, when the pump is automatically disengaged. The motor is started by pressing a button.

The air tank, which is 8 by 42 inches, may be located under the car. Sixty pounds pressure is all that is necessary to operate the biggest motors, but the maximum pressure generally carried in tank is 150 pounds for large cars and 80 pounds for cars of the Ford type. The automatic control is adjustable, so that it may be set in a moment to operate at any desired maximum and minimum pressures. An outlet at the pump, with hose connections, is also provided for inflating the tires.

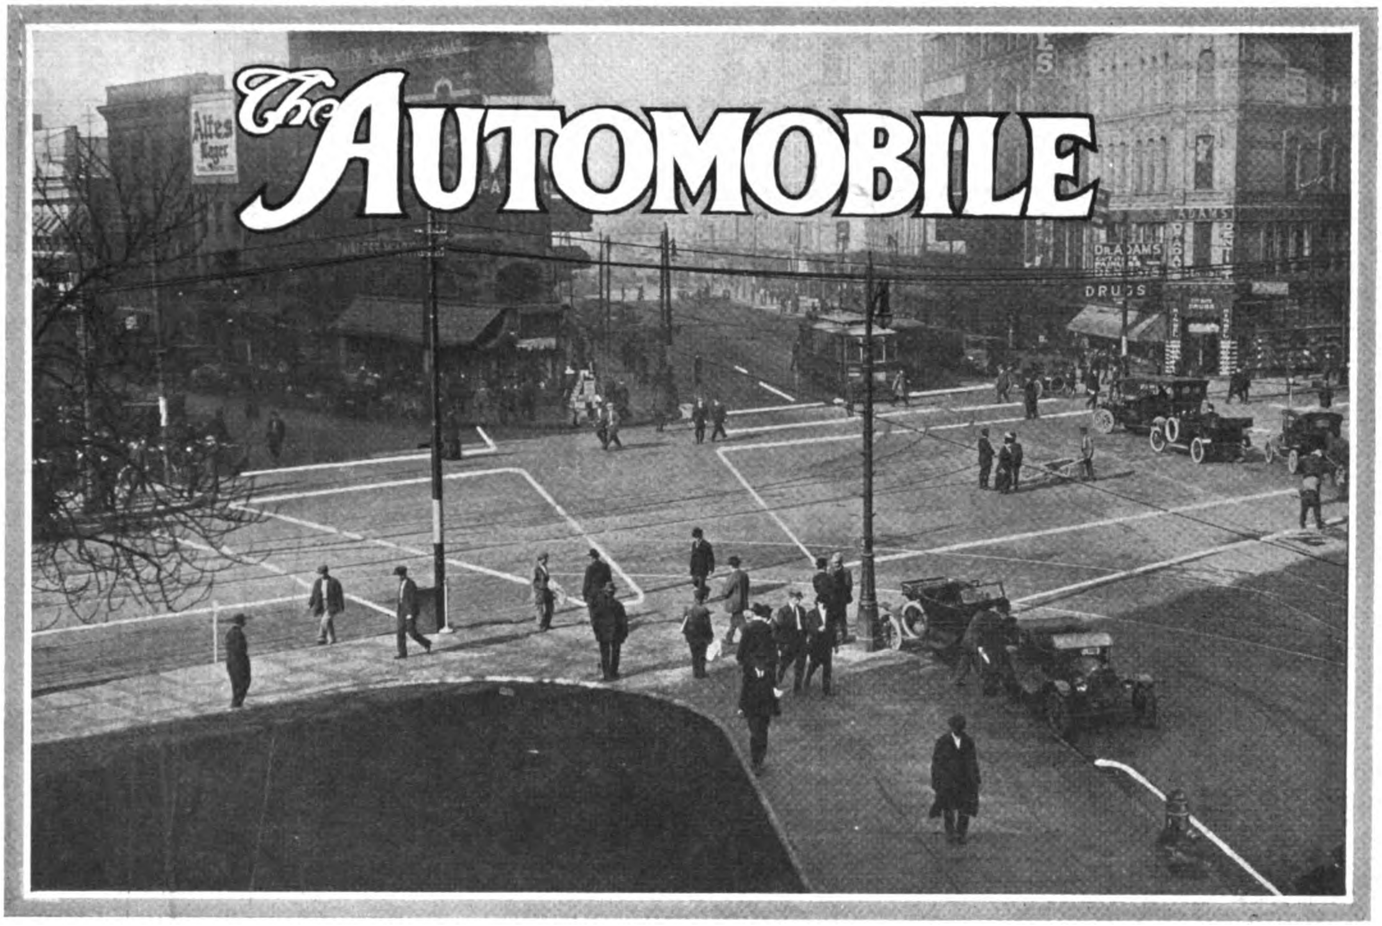
VOL. XXXI NEW YORK—THURSDAY, NOVEMBER 12, 1914—CHICAGO No. 20



View in Detroit at Griswold, Lafayette and Michigan at 10 a. m., showing the tennis-court traffic lines

Tennis-Court Traffic in Detroit

Automobiles, Trolleys and Pedestrians Regulated by Chalk Lines

By Marc Braun

TRAFFIC runs along chalk lines in Detroit. When a man is said to "walk a chalk line," he is known to be well ordered, disciplined, regulated. Detroit's down-town streets are actually chalk-marked and automobiles, coal wagons, shoppers, messenger boys and tired business men are hop-scotching along the white boundaries from block to block in perfect order and without complaint.

The Neutral Zones

When you cross a street at a down-town corner, the lane in which you are supposed to walk from side to side is bounded by white lines on the pavement, almost duplicates of the lines marking a tennis court. When you get into the middle of a busy street to board a trolley car, there is marked out in white a safety zone for you to stand in and on the confines of which the heavy horse dray, the motor van or the bicycle must not encroach. At the fire hydrant are found the tennis-court lines declaring in silent tones the neutral zone on which you must not park your automobile, lest it interfere with fire apparatus in the event of a fire. Along the curbs in the down-town section are zones telling you where you can and where you cannot park your car. Along the curb at many places are conspicuous signs telling you to park your car "parallel to the curb" or "at an angle to the curb!"

There are more automobiles in proportion to area and population in Detroit than in any other American city. Also, there is only one main popular thoroughfare, Woodward avenue, leading into the heart of down-town Detroit. The congestion that

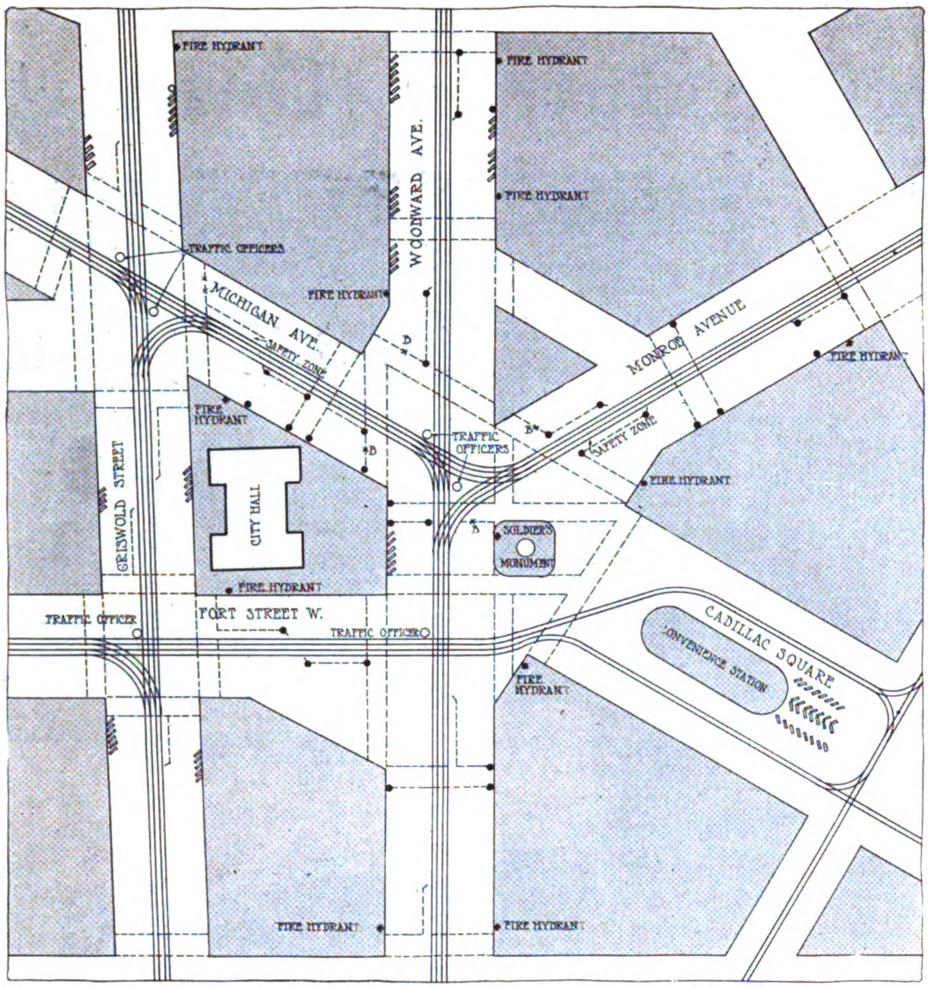
Above—A view on Woodward avenue at 2 p. m., looking from State street. Note the cars parked diagonally to the curb

Right—How each fire hydrant is marked out with safety zone to insure ample space around it for the firemen to work in case of an alarm from that district



How the tennis-court system of regulating is laid out in Detroit, as exemplified by the central business district of the city. Traffic officers are indicated by rings. Black dots indicate posts supporting notice boards relating to parking of cars, etc. At the points B all automobiles and other vehicles must stop to await the traffic officer's signal to proceed. Note cars parked at the curbs. Also note crossing places and safety zones

results impelled an entirely new method of traffic government.

Tested first last June, the new system is now permanently adopted. Its approval by traffic experts probably will result in similar street markings in many other cities.

The marked lanes are supplemented by a variety of sign posts that not only are educational in relation to the new system but have the Safety First legend.

Rush-hour jams, jay driving and jay walking, and accidents at street car stopping points have been diminished by the new chalked boundaries.

The Tennis-Court Boundaries

The street-crossing lanes for pedestrians are generally 18 feet wide, the same width as that of the sidewalk, and the white lines of chalk extend from sidewalk to sidewalk.

At street car stopping places the white lines indicating the safety zones are 60 feet long or the length of one or two street cars. The line is drawn 6 feet from the car line tracks.

Along the outer white line of the pedestrian street crossing zones there are posts bearing the words: "Crosswalk—By Order" or simply the word "Walk" under a cross. At the end of the white line near the street car tracks there is generally a post bearing the words, "Safety First."

Parking Regulations

Near fire hydrants posts are generally placed either in front or on both sides of a white line and the words, "Hydrant—No Parking—By Order," are on it.

On those sides of the street where no cars must be parked or where they are to be parked only within certain space, there is generally one or several posts bearing inscriptions like these: "No Parking Allowed on this side of Michigan avenue," "Cars must not park within this space."

Near street car stopping places at street crossings automobiles and other vehicles may not be parked for a distance of 75 feet.

In front of public buildings, banks, theaters, one or more posts are generally in place on both sides of a space of 15 or 20 feet to permit people to alight from their car.

In the avenues or streets which are wide enough automobiles are parked obliquely while in most side streets along Woodward avenue they are parked parallel with the sidewalk.

On certain thoroughfares traffic is permitted only one way.

The various posts have the warnings painted in black upon white while the white safety posts have the words "Safety First" painted in red. All post warnings have the words: "By order of the Police Department," or the words, "By order" under the warning inscription.

The System's Area

The new traffic system, which at first took up only a few of the most congested business blocks in the heart of the business district, on Woodward avenue and some of the side streets, was quickly extended and now comprises a section of the city extending along Woodward avenue from Jefferson to Warren in length, and from Randolph to Shelby in width. This is an area having dimensions of fourteen blocks by four. A few other streets and sections of Woodward avenue having heavy traffic are similarly regulated.

At the present time fifty-four traffic officers are on duty daily on the streets within those blocks. Some start at 7 in the morning, some at 8, and while they work in shifts some are on duty till 8 in the evening in the business district.

Generally only one officer is at a street crossing, but there are places where two and more men are required. For instance at Woodward and State streets four traffic men are on duty from 4.30 to 6 p. m. At this particular crossing, it was claimed by one of the traffic men, more automobiles, street cars and pedestrians cross during the hours of 4 and 6 than in any other city in the country, with the possible exception of New York.

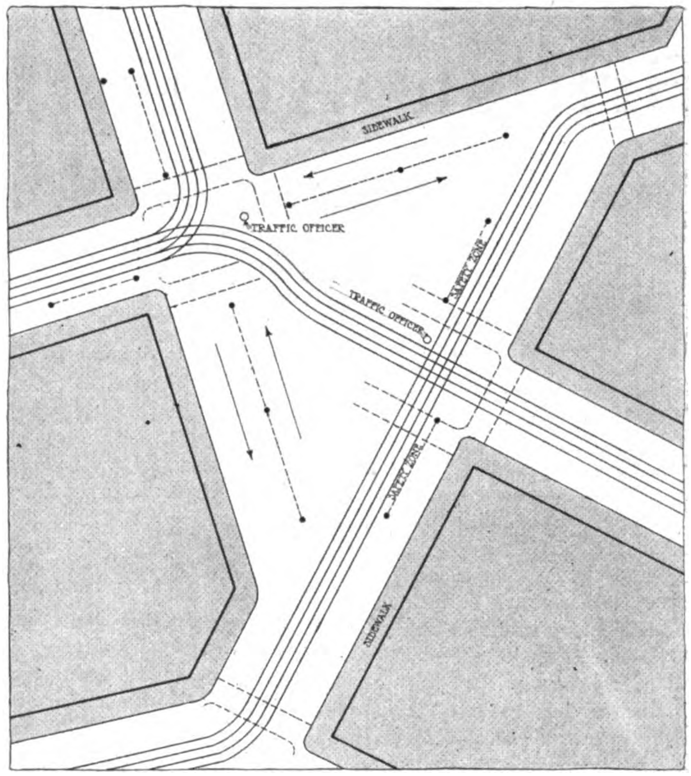
The one main thoroughfare to the business district, the theatres and the principal hotels is Woodward avenue. Practically all automobile drivers use it to come to their places of business and to drive home. Most of the side streets are rather narrow and poorly paved and have street car traffic.

Parking the Cars

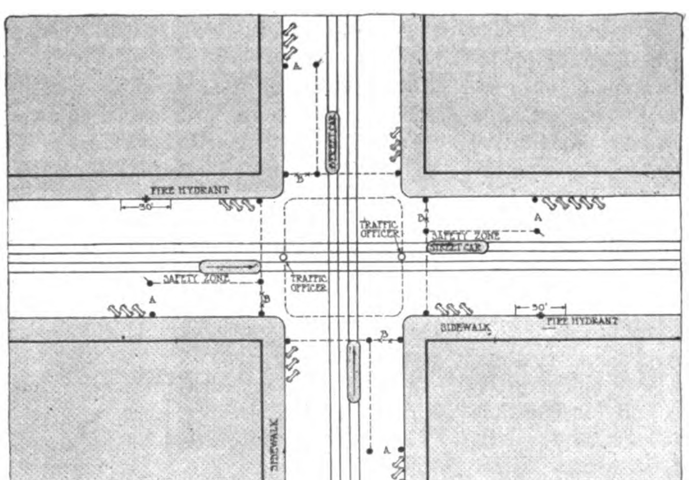
Most automobile owners or drivers leave their cars in the street in front of their building. Thus most of the streets have cars parked on both sides, sometimes parallel with the sidewalk and mostly obliquely with the sidewalk.

This oblique parking system has given excellent results as it permits about three times as many cars to remain within a city block than in the old way of having the car backed in full length against the curb of the sidewalk. To give an idea of the improvement a count was made of the number of cars actually standing along the sidewalk from Campus Martius to Grand Park Circus, on Woodward avenue, between 4 and 5 o'clock of a certain day. Within the four city blocks there were 190 cars parked, ninety-six on one side and ninety-four on the other side. These 190 cars took up a total space of 1,520 feet by being parked obliquely instead of one behind the other, in which instance the total space required would have been 2,280 feet. Thus the new way means a saving of 760 feet of space, or at the very lowest, the equal of two city blocks.

There are only twenty-one garages in the quarter-of-a-mile circle which starts from the city hall and which territory comprises 150 city blocks. Fully two-thirds of the 2,000 to 3,000 cars which are parked along the streets daily are found within less than twenty-five of these 150 city blocks. The twenty-one garages could accommodate 1,426 cars on a basis of fairly prompt service, which means that it would require an average of 5 minutes at least to get the car in or out. In some cases it would require fully 10 minutes.



How the triangular street intersections are treated in the Detroit tennis-court system of regulating traffic, showing crossing places, sidewalks and safety zones besides trolley car stopping places



A typical street intersection. No parking is allowed within the space indicated between A and B on each street. Method of parking cars, safety zones, posts of traffic officers and crossings are shown as well as fire hydrant zones

While, figuratively speaking, the 2,000 or 3,000 cars remain on the streets from about 10 in the morning till 5 in the evening, from 40 to 50 per cent. of these cars are used from time to time during the day by their owners and thus it would not be practical, on account of loss of time, to have them in garages.

City Statistics

The total number of automobiles now operated within the 42 square miles of city territory is estimated at between 21,000 and 22,000 according to the officials of the secretary of state's department. City officials say that the city now has very near 620,000 inhabitants and thus on the basis of 21,000 cars there is one automobile per thirty Detroiters and 500 automobiles to the square mile of city land.

When the new traffic regulations were tried for the first time most of the traffic officers did not believe that the people would give much attention to the broad white chalk lines at street crossings. Neither did the officials think that the safety zones at street car stopping places would be found real safety aids.

But from the very first day it seemed that all Detroiters understood the undeniable advantages of thus being provided with safety walking spaces or lanes, and pedestrians and drivers of horse and non-horse vehicles showed a decided disposition to "be good."

British Army Truck Efficiency

Organization Is Most Complete—Facilitates Food Distribution—Some Problems

By J. M. C. Rowley
Special to THE AUTOMOBILE.

PARIS, Nov. 1—Nothing approaches in efficiency the work of the ordinary motor truck in the service of the British Army Service Corps, the most thoroughly organized army service corps in the world. The work of those trucks is wonderful and the drivers no less ask to be praised. Back of the fighting line I have seen them tearing along those fine French roads fully laden, frequently entering into the line of fire having to pass gaps when the enemy's forces are not directly opposed.

That admirable distribution of food supplies which has been a characteristic feature of the allied army is immensely facilitated by the trucks running from post to post carrying provisions which are afterwards taken to the regimental base and from there frequently to the men in the trenches by orderlies who run great risk in so doing. I was wondering whether small armored tri-cars could be used for such field distribution, and discussed the subject with a sergeant, but he was inclined to think that across field work would be too heavy for them. It would be interesting, however, he admitted, to have such a small car designed with powerful motor and heavily armored.

More Armor Needed

I met three British armored cars this morning along the high road leading into Paris. The radiators were practically unprotected. Is it absolutely essential that the radiator should be directly in front of the truck or car? A distribution of air could be made by radiators placed at the sides, so that the front of the motor could consist of a solid steel plate.

Still, the radiator danger is minimized because it is very rarely that a truck or car would come face to face with the enemy's fire. A truck's principal duty in actual warfare is to link up the line of operations. In the present campaign the line is immensely extended and exceedingly elastic. It is the automobile that renders this possible. I am firmly convinced that such a huge front between two armies of such power as those of the German and the Allies could not be kept without the automobile.

As an actual instrument of attack the motor car is not being used. It was tried by the Germans in Belgium, twenty cars charging in line, but failed. It is very rarely that sheer weight wins in a charge against skillful opponents.

No Trucks in Paris

In this city I have seen no commercial vehicles of any kind, except one—engaged in ordinary commercial work. In fact, all commercial work seems to a very large extent, to have failed. A Frenchman connected with the motor business told me the other day of what a lot of trade had been done in automobiles by Germany with Russia, the Balkan States, Belgium, South America and Italy. Especially so was this the case in regard to Russia, and, if ever there was a big field now for motor vehicles *asking* to be captured, it is in Russia.

In France and England all private cars are being utilized—for very varied purposes. As ambulances their value is great, and 500 cars are to arrive immediately in France for the British Red Cross society. They enable the wounded to arrive at the hospitals three or four times quicker than by train. Again, the cars are being used to take convalescent soldiers for a ride when they are able to go out into the open. The American Red Cross branch is exceptionally well organized in connection with automobile conveyance.

The British officers are all one in praising the work of the automobile. Perhaps its practical value is greatest as a conveyance for orders, a mechanical aide-de-camp. I have been out three times with the Red Cross to the battlefields and noticed scarcely any ruined vehicles, so conclude that they do not operate in the immediate field of action, and they are very effective in operation, suffering very little mechanical trouble.

A wounded truck driver has told me how his truck, a 3-ton, was in operation practically all day, he and his comrade serving as shifts. It was used for conveying food supplies from a base to the camps. The conveyance over fields is difficult and the truck is of practically no value. Lately, too, the roads in the field of operations have been muddy and sticky with clay and it has been difficult to operate any trucks heavier than 3 tons. That capacity is found to be most universally useful. The solid tires are wearing well, although there is great tendency to pulp up in certain parts. The wear and tear on a solid rubber tire does not seem to be at all regular, bumps seem to break off, and some I have noticed in ruined condition, although the vehicles still bump along.

How Trucks Are Used

The quick retreating and advancing movements that have been a special feature of the present campaign have been made possible *only* by the motor vehicles. Infantry can cover 30 miles during the day easily, while the cavalry can move trebly as quick. But an army has always been retarded by its baggage; it clogs the wheels of movement and hangs like a millstone round its neck. Thus, the perils of short rations and ultimate starvation were always to be expected when large bodies of men were engaged in very quick movements over a large stretch of country.

The German army is extremely quick in movement, that is movement en masse. Yet without similarly adequate methods of conveying baggage and supplies, their operations would have been futile. The motor vehicle has given both armies the additional wing which enables them to pursue or fly, as the case may be, so swiftly.

It is hard to imagine with what an extremely difficult problem a quartermaster is faced in actual warfare. It is hard enough in mimic operations. But when life depends on the skill of his arrangements, its difficulty is accentuated to the extreme.

It is not permitted by the censor to name positions, but let me illustrate this by an actual example. Take the following diagram:

ABC represent the retreating army corps of the Allies.

DEF represent the attacking army corps of the enemy.

The ABC army till now has been attacking; and has always kept its base of supply well behind the center B. The army arrived at the banks of the river, but found the defenses very strong all along the opposite banks, so it was found necessary to retreat in the direction from which they had come, namely, that opposite to the arrow in the diagram. Accordingly the retreat commenced in a northeasterly direction, but to the northeast it was found to be impossible to proceed as it was necessary to concentrate all force with M on the further side of the river, faced by a large body of the defenders, N, subsequently the attackers. A retreated quickly to the base G, B advanced in front of base of supply attacked by E and F. D crossed the river, and swept northwards, threatening the rear of the base of the supplies by an attack on the right flank.

The commander at G had a most serious problem, and had it not been for motor vehicles it would have been impossible to save the supplies, and as a consequence the forces A and M would have been cut off, B and C perhaps effecting a retreat to the northeast. But the base G was able to move as quickly as the attacking force in flank D and sped in the rear of C, B waiting to protect the retreat. The base moved easterly along the river, C crossed and joined M and A and B took up a position of strength along the river bank. It was because they were able to move at a moment's notice their basis of supply and with equal celerity to the approach of the attackers that the army was then saved. It is when a base feeds numerous armies liable to be separated that the quartermaster finds difficulty.

Collecting the Wounded

Ford cars are much used, but chiefly as messenger carriers. Only big cars are of any use for the transportation of wounded. I saw one transport car loaded and loaded again with wounded all higgledy-piggledy, poor fellows! But taken as a whole, the arrangements for the wounded are excellent.

A certain number of automobiles usually arrive at a certain central position immediately in the rear of the seat of action, covering an area which is called the area of the field ambulance work. At the front of this there is a dressing station, or, rather a number of dressing stations, fed by the ambulance bearers from different points of the field. From the dressing stations the wounded are conveyed to a kind of clearing-house, where they are distributed to the general base hospitals, and it is here, of course, that the automobile is so useful. In former times it was along this route, often over a long distance, that many of the wounded succumbed, but the automobile links up the field with the base.

The front has to be cleared first. That is done in double-quick time. Now, there is little delay in sending the wounded to the base hospitals, the one place, of course, where proper aid can be given them. Many wounded seem to be arriving unwashed and with their wounds undressed, while men suffering from epidemics are frequently near to those not so afflicted.

The German advance through Belgium on to the northeast provinces of France was one of the quickest movements ever executed in military history, being of tremendous extent in line and face to face all the while with an active and sheltered enemy. What was the principal agent in the German advance? What enabled that huge arm pivoted in Luxembourg to sweep with massive vigor against northeast France and crash toward Paris? What kept the regiment of that arm united? The motor vehicle.

The German army possesses a bigger, stronger and more thoroughly organized system of motor traction and inter-communication than the allied forces, and I understand that there are many thousands of vehicles ready at a moment's notice to take the place of injured cars, although the number of the latter is comparatively slight.

Russia has a huge fleet, but there is very little detailed news coming in from the Galician frontier, and I have not yet been able to secure any information relative to the immense work which must have been done by motor vehicles in the mobilization of the Russian army—a work, by the way, of wonderful celerity Their work will have to be suspended, however, during the coming winter as during this season the roads in this district are in many places impassable.

German Armored Cars

The German car for war work is much more often armored than that of the Allies. All the cars seem to have been commandeered touring cars fitted with plates of steel, protecting all the vital parts and frequently the occupants. I noticed several of these in Antwerp captured in action by the Belgians, some being those, it was said, used by the Kaiser in a mad motor charge full in the face of a pitiless fire. The machine didn't seem injured in any way and in most cases it was the driver who was shot before the car was damaged. He was supposed to be protected by a steel plate in place of the windshield, but this was ineffective protection, the side of the driver's seat being open and leaving the driver exposed to fire.

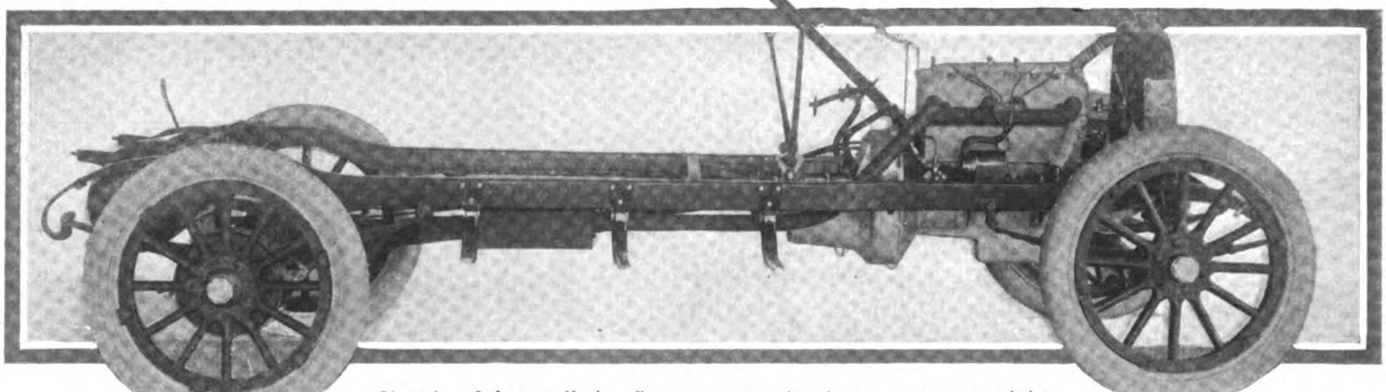
Dodge Is Streamline Touring Car at $785

Block Four-Cylinder Motor 3 7-8 by 4 1-2—Five Passenger Body—Complete Electric System



Chassis of four-cylinder five-passenger touring car announced by Dodge Bros., Detroit, Mich., to sell for $785 with complete equipment

ALL the mystery about the Dodge Bros. contribution to the world of motoring has been cleared away with the announcement this week of the make-up of the car. Even the price speculation has been quieted, for it is set at $785. Furnished only in five-passenger touring form, the Dodge car is a streamline machine of sturdy mechanical construction. The specifications include a block-cast, L-head motor, 3 7-8 by 4 1-2 size; gearbox in unit with the engine; drive through a propeller shaft inclosed in a torsion tube to a floating rear axle; cone clutch; three-quarter elliptic rear springs; overslung frame; and left drive with center control.

The wheelbase is 110 inches, and tires 32 by 3 1-2 all around, the rear set being of the non-skid variety. Equipment is of note in view of its completeness, taking in such items as North East combination motor-generator set for cranking and lighting, Eisemann magneto, Jones speedometer, one-man top, rain vision and ventilating windshield to which the front of the top fastens, Willard battery, etc.

The body is a trim affair being an example of all-steel construction. Even the frame is of steel. Upholstery is of machine and hand-buffed leather. The body and bonnet are united without any disturbing lines due to the consistent slope of both cowl and hood, which is finished out with a radiator of the coped-over edge type. The fender construction is good, being of the oval molded type rounding into the splashers.

The cowl board arrangement shows that the instruments necessary in driving are placed a little to the drive side of the center. To the right of them is a small compartment with a lock which may be used for carrying gloves, etc. The instrument panel is of pressed steel.

The motor, S. A. E. rating of 24 operates with a compression pressure of 65 pounds per square inch. There is no question that this motor is amply powerful for the car, for with a ratio of stroke to bore of 1.16, it has a displacement of 212.3 cubic inches. When the car is running at about 10 miles an hour on high, the motor is turning over at 380 revolutions per minute.

Separate Cylinder Heads

The general arrangement of the motor is of the type in which the cylinder head is a separate piece, bolting to the cylinders. The intake passages are cored through the single-opening to the carbureter on the left to the intake ports on the right, the cored passages being between cylinders Nos. 2 and 3. The exhaust manifold is a separate casting with an opening individually from each cylinder. A single long plate incloses the valve mechanisms.

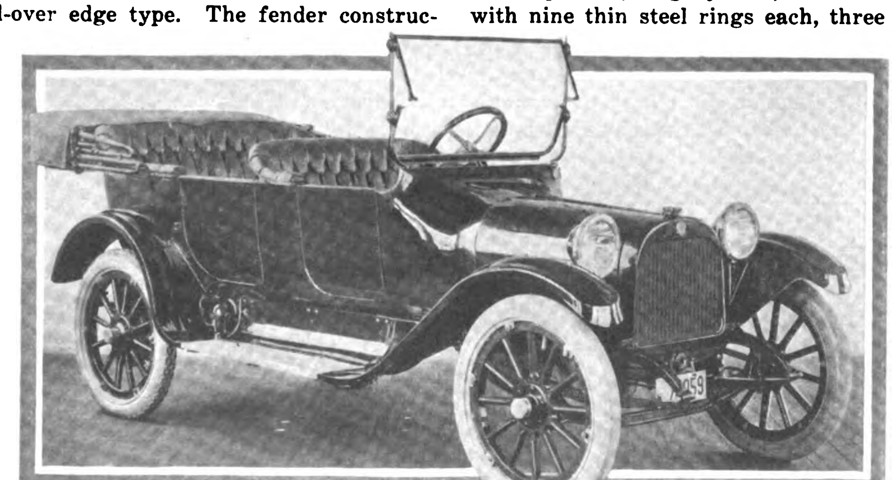
On the left is mounted the motor-generator in addition to the carbureter, and the magneto and water pump are placed on the right.

The suspension of the motor is three-point.

The Reciprocating Parts

The pistons, of gray iron, and 4 3-8 inches long, are fitted with nine thin steel rings each, three to a groove. Connecting-rods attach to the pistons by 13-16 inch pins held to the pistons by set screws, the rods bearing on them with 1 3-4-inch phosphor bronze bearings. The rods are vanadium steel drop forgings of usual H-section, and measure 9 1-8 inches center to center of bearings.

The crankshaft is of the same material as the rods and rotates on three brass-backed babbitt



New Dodge car, showing streamline five-passenger body, rounded-over edges on radiator, smooth doors, etc.

bearings. The rod bearings are of the same material. The crankpin diameter is 1 1-2 inches. The three main bearings are 1 5-8 inch diameter, and their lengths are 2 15-32 inches front, 2 1-4 inches center and 2 19-32 inches rear. Like the crankshaft, the camshaft is a vanadium steel drop forging and has the same number of bearings. It operates through steel timing gears housed at the front.

The valves, of 1 9-16 diameter in the clear, have vanadium steel stems and springs. Their lift is 5-16 inch.

Circulating-Splash Oiling

The oiling is by the circulating splash scheme which makes use of an eccentric pump driven by spiral gear on the crankshaft. It feeds oil through a pipe lying along the roof of the crankcase, this pipe being drilled to throw jets of oil into the troughs under the connecting rods and into pockets above the crankshaft and camshaft bearings. From these points the oil finds its way back into the oil pan where it is filtered and made ready for re-circulation.

Cooling is by a centrifugal pump driven at crankshaft speed and operating in conjunction with a six-blade pressed steel fan belt driven from the pump shaft, which is carried on an adjustable bracket to take up belt stretch. A 5-quart radiator of tubular construction with six rows of twenty vertical tubes each is the main cooling agent. The total waterjacket capacity is 2 gallons.

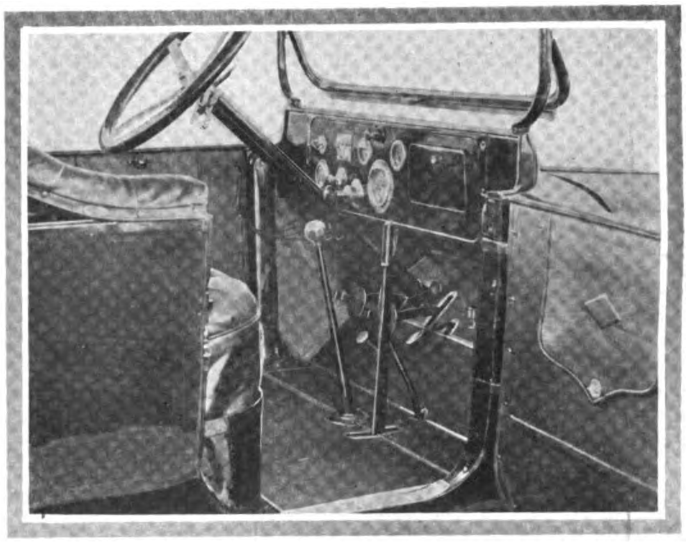
The ignition current is supplied by an Eisemann G-4 high-tension magneto of waterproof type. This is driven from the end of the pump shaft and it connects to a set of A. C. spark plugs with the firing order 1, 3, 4, 2.

Motor-Generator System

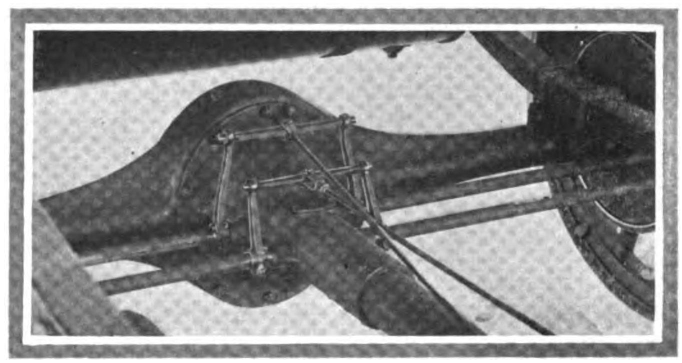
The combined motor-generator which takes care of all electrical requirements except the ignition is a North East 12-volt unit, mounted on the left forward side of the engine and driving through an inclosed silent chain from the crankshaft with a 3 to 1 reduction. It operates in the regular way either as an electric motor for starting or as a generator for charging the battery and lighting the lamps. The battery, carried under the left front seat, is a 12-volt Willard of 40 ampere-hours capacity.

The starter pedal is placed in the center of the toe board, and after switching on the ignition, it is only necessary to press this pedal to turn the crankshaft with a torque of 35 foot-pounds. After the starter pedal is released, the unit automatically becomes a generator.

Connection between motor and final drive is by a cone clutch having spring inserts under the leather facing. The cone has a mean diameter of 14 inches and the face width is



Driver's compartment of Dodge car, showing left drive and center control and instrument board



Dodge rear axle, showing torque tube carrying driveshaft. Note brake equalizers

1 3-4 inch. It is inclosed within the integral extension of the gearbox which forms the flywheel housing and bolts to the crankcase.

The gearset is a three-speed, selective, sliding type, one which is unusual in that when on direct drive the countershaft gears do not rotate.

The train of gears driving the countershaft is shifted out of mesh when the dental clutch connecting mainshaft direct to power shaft is engaged. The gears are constructed of

The Rochet-Schneider factory at Albert, Sommes, France, destroyed by the German army. The main plant is at Lyon and is safe

French Factories Suffer in War

One of Rochet-Schneider Plants Destroyed

By W. F. Bradley

PARIS, Oct. 23—Owing to the severe censorship, travel restrictions, and the complete stoppage of all civilian automobile traffic, it is difficult to obtain accurate information regarding the fate of the factories allied to the automobile industry. Practically all these establishments—foundries, steel works, sheet metal works, etc., are in the north and northeast of France where the most severe fighting is taking place. Probably annoyed at their failure to get within striking distance of Paris, and the serious setback they received during and since the battle of the Marne, the German troops have made systematic attacks on French factories. If she cannot gain a military victory, Germany appears determined to crush the industrial development of France.

The Rochet-Schneider motor factory at Albert, in the Somme department, has been wantonly destroyed. Before entering the city the Germans shelled the factory, and on gaining possession of the town they completed their work by setting fire to the wrecked buildings. Blackened walls and twisted iron are all that remain of the works. The deliberateness of the attack is shown by the fact that the buildings around the factory have been spared and the conspicuous town hall, visible several miles away, has not been damaged.

Main Plant Is Safe

The main factory of the Rochet-Schneider company is at Lyon, well out of the military zone. The works at Albert are occupied largely with the production of bicycles and motorcycles and various accessories. In connection with the photograph of the wrecked factory, which was secured immediately the Germans were driven out of the town, it is interesting to note that the photographer was arrested on the suspicion of being a spy, was handcuffed and kept in prison for several hours. He was released and considerately treated by the French authorities on his identity being proved, but so thorough is the spy hunting campaign that the incident failed to excite attention or to call forth an excuse. Newspaper men and photographers in the war area must be prepared for this.

Directions for Oxy-Acetylene Welding

Specific Instructions for Welding Cast Iron, Malleable Iron, Aluminum and Alloys, Copper, Brass, Bronze, Etc.—Speeds in Work—Educating the Workman —Fluxes—Cutting Metals by Oxy-Acetylene Flame

By H. Sidney Smith
Engineer Prest-O-Lite Co., Inc.

INDIANAPOLIS, IND.—Editor THE AUTOMOBILE:—In the automobile field the savings that can be effected by acetylene welding are enormous. This industry provides welding with a unique field. The process is generally employed for repairing cracked cylinders, gear-cases, building up teeth on gears, repairing and reinforcing broken frames, constructing exhaust manifolds, etc.

As the process becomes more developed there is no doubt that it will be employed in the construction of motor cylinders built up from sheet iron parts welded together, especially in the case of aeroplane engines where light weight is an essential feature.

Flame for Hardening

The oxy-acetylene flame is now employed extensively for hardening the wearing surfaces of steel parts: it is applicable to such purposes as the hardening of the surfaces of gear teeth, template holes and in general to the local hardening of any small area upon a large piece, especially where case-hardening might cause distortion which it would be difficult to remove by grinding. The feature of the process is the quick transit of an intensely hot flame over the surface to be treated, so that it is raised in one continuous wave to hardening heat, and then as rapidly cooled as soon as the flame has passed, by the coolness of the remaining metal, leaving the surface at the maximum hardness the composition of the steel will allow. The hardening will be found to penetrate to a depth of about 1-16 inch.

In the tool room the process is found of service, especially in the construction and alteration of jigs, and economy in the use of high-speed steel can be effected by welding short pieces to lengths of inferior steel.

Blowpipe Welding

Oxy-acetylene welding is a process by which pieces of metal are melted and joined together by means of a flame of sufficiently high temperature, and additional metal of the same composition added if desired. The joint thus obtained is today commonly called an autogenous weld. As a matter of fact the weld obtained by forge welding or by the electrical process can be called autogenous, as use of a metal cement is not necessitated as is the case with a brazed joint. But it is general today to use the term autogenous weld only in connection with welds effected by means of a gas blowpipe.

Flame temperatures produced by the combustion of a fuel gas in air or oxygen depend on two factors, the calorific value of the fuel gas and the nature of the products of combustion. Taking the case of a fuel gas with a high calorific value burning to products of low specific heat, we have a flame of high temperature, but if the products of combustion have a high specific heat the flame temperature is lowered proportionately. As an example, suppose we burned sufficient hydrogen to produce a fixed number of heat units, and then burned sufficient carbon to produce a similar number of heat units; in the first case the product of combustion would be water vapor and in the other carbon dioxide (CO_2). Water vapor, however, has a much higher specific heat than CO_2; hence the temperature of the hydrogen flame would be low as compared with the carbon flame or fire, as the flames have to supply the heat to raise the temperature of the products of combustion.

Gas Characteristics

With the exception of hydrogen, all fuel gases burnt with oxygen in a blowpipe consist of carbon and hydrogen, and therefore their combustion results in the production of water vapor and carbon dioxide; the less the quantity of water vapor produced, the higher will be the flame temperature. It will, therefore, be appreciated that the gas having the highest percentage of carbon will produce the highest flame temperature. Acetylene (C_2H_2) has a higher specific gravity and calorific value than any of the commonly employed fuel gases; it contains but about 7 per cent. of combined hydrogen and is the nearest possible approach to gaseous carbon. Pintsch, natural, coal, Blau, water, and other fuel gases all contain 2 to 50 per cent. free hydrogen and also more hydrogen in combination. This hydrogen burns to water vapor, which, as before stated, has a high specific heat and will absorb heat and lower the flame temperature.

Oxy-Acetylene Welding

Oxy-acetylene welding was first practiced about 13 years ago. Previous to that time it had been fully appreciated that wonderful results would be obtained from using oxygen and acetylene in a blowpipe, but it had been found impossible to construct a blowpipe that would consume acetylene at low pressure. Acetylene under pressure then came on the market and the blowpipe difficulty was soon overcome.

At a later date, injector blowpipes were produced which permitted a low-pressure acetylene being employed. Experience has proved that the best results are obtained when acetylene is delivered at the burner tip under considerable pressure. Today it is usual to obtain acetylene from a pressure generator or from a cylinder of dissolved acetylene with any type of blowpipe, or to use an injector-type blowpipe drawing the acetylene from a low-pressure apparatus with excess of pressure on the oxygen supply to provide power to suck in the acetylene and deliver the mixture of gas to the blowpipe nozzle at a suitable pressure. However, there is no doubt whatever that in order to obtain economy and really satisfactory working, both gases should be delivered to the blowpipe under pressure.

One volume of acetylene (C_2H_2) requires theoretically 2 1-2 volumes of oxygen to burn it completely to its products of combustion, which are carbon dioxide and steam; but in actual practice it is found that 1.1 or 1.5 volumes of oxygen only have to be supplied to the blowpipe to 1 volume of acetylene, depending upon the nature of the acetylene supply and the blowpipe employed.

Qualities of Gas

Acetylene is an endothermic gas and immediately on issuing from the nozzle of the blowpipe dissociates or splits up into its two constituents, carbon and hydrogen. The carbon burns with the oxygen supplied through the blowpipe to form CO, producing the white flame at the nozzle. In order to form CO, equal volumes of acetylene and oxygen are required, but then another phase of combustion takes place; the CO burns to CO_2 and the hydrogen later combines with oxygen to form steam. If a blowpipe could supply an absolutely perfect mixture of equal volumes of acetylene and oxygen at its nozzle, the remainder of the oxygen required to burn the CO to CO_2, and the hydrogen to steam, could be extracted from the air. This has not yet been quite attained and in practice some of the oxygen required to burn the CO to CO_2, has to be supplied through the blowpipe, although as stated above, the best blowpipes produced today require only 1.1 volumes of oxygen to 1 volume of acetylene.

It should be understood that the hydrogen combines with the oxygen of the atmosphere only after it has passed away from the high temperature zone of the white welding flame, the temperature of which is about 6300° F., at which figure it is impossible for steam to exist, as it is far beyond its dissociation temperature. The result is that the molten metal is surrounded by free hydrogen, tending to prevent oxidation, the hydrogen also protecting the inner, or welding, flame from loss of heat.

Two Types of Equipment

There are today in the field two styles of welding outfits, commonly known as the high- and low-pressure systems. With the low-pressure system the acetylene is supplied from an acetylene generator which delivers gas to the blowpipe at a pressure of 2 or 3 ounces, and the oxygen is supplied under pressure in an ordinary trade cylinder. The low pressure of the acetylene supply necessitates the employment of blowpipes of the true injector type, in which excess pressure has to be used on the oxygen supply in order to suck in sufficient acetylene and deliver the mixture of gases at the blowpipe nozzle at a proper pressure. With this method it is more or less impossible to get perfect mixtures of the gases, and the oxygen consumption is undoubtedly higher than when both gases are supplied under pressure. A certain unsteadiness of the flame also has to be contended with. Notwithstanding its drawbacks the low-pressure generator system has one important point in its favor as compared with the high-pressure generator system, namely, that the insurance companies look upon it with much less disfavor.

The high-pressure system of oxy-acetylene welding may be sub-divided into two classes: first, the plant in which the acetylene supply is obtained from a generator which delivers and generates the acetylene gas under pressure; and second, those plants which employ cylinders of dissolved acetylene instead of the high-pressure generator. With both these styles of plants, any type of blowpipe can be employed, and as both gases can be delivered to the blowpipe under pressure, a nearly perfect mixture of gas can be delivered to the blowpipe nozzle, which is not the case when the oxygen only is delivered to the blowpipe under pressure, as in the low-pressure system.

High-pressure acetylene generators are looked upon with disfavor by all insurance companies, and in some cities their use is prohibited by the authorities on account of the many accidents which have occurred through their employment. They are, as a rule, designed to deliver the gas at a pressure not exceeding 15 pounds to the square inch. Under this pressure acetylene, if it has no air mixed with it, is not explosive, but at times the class of generators under consideration gets out of order, excess pressure frequently being the result. At 30 pounds pressure acetylene is explosive, and between 15 and 30 pounds its action is somewhat uncertain.

Using Dissolved Acetylene

Where dissolved acetylene is employed instead of a high-pressure generator, immunity in respect to accident due to excess pressure is obtained, due to the fact that the acetylene while under pressure is stored in a porous mass contained in the cylinders, which makes it quite impossible to propagate an explosion through it. Acetylene, when delivered from the generators always contains a small percentage of impurities which are, as a rule, ammonia, sulphuretted and phosphoretted hydrogen. These can be eliminated from the gas if proper purifying apparatus is installed with the plant, but this is very seldom done, with result that the gas delivered from the high-pressure generators always contains a small percentage of the impurities mentioned above. Any one familiar with the working of iron and steel will appreciate fully what will occur if molten iron or steel is brought into contact with the gas containing phosphoretted and sulphuretted hydrogen. When dissolved acetylene, however, is used, instead of a generator, this possibility is overcome, due to the fact that manufacturers of dissolved acetylene always wash, dry and purify their gas before compressing it into cylinders.

Impurities in Weld

Many tests have been made to find what effect the presence of phosphoretted and sulphuretted hydrogen has on a weld. A number of gasoline and gas containers were welded, some with unpurified gas drawn from an acetylene generator, and others with gas drawn from a cylinder of dissolved acetylene. All the welded vessels were tested under pressure, and it was always found that those welded with the unpurified gas did not survive as well under the test as did the others. It may also be noted that when impure acetylene is used the welding flame is colored and much more difficult to regulate.

Users of acetylene generators are apt at times to overload them, with the result that there is undue heating. This heating may cause polymerization, or breaking up, of the acetylene itself. The presence of this altered gas in the pure acetylene will cause changes in the welding flame which affect very seriously the work and necessitate the use of more oxygen than if the acetylene were in a pure state. A cylinder of oxygen and a cylinder of acetylene can be moved readily on a truck to any position in a shop desired, whereas an acetylene generator should be stationary, although there are today on the market various acetylene generators which are stated to be portable. These, however, are not really suitable for welding work, as they are too small to generate gas fast enough to feed the blowpipes without undue heating, which, as mentioned above, is not only dangerous but deleterious to the acetylene itself.

Making Oxygen

Very few users of the oxy-acetylene process manufacture their own oxygen, but purchase it from the large oxygen manufacturers. For commercial purposes oxygen is manufactured by either the liquid air or the electrolytic process and can be obtained in a state of comparative purity from either class of plant. Any impurity contained in oxygen manufactured by the liquid air process is mainly nitrogen, and while freedom from nitrogen is desirable a slight percentage is not fatal to good welding of iron and steel. However, should the percentage of impurities exceed 1 1-2 per cent. the welds will be somewhat porous, due to the absorption of the nitrogen by the molten metal.

The purest possible oxygen should, however, be procured for welding aluminum, copper and brass, as at high temperature these metals have a strong affinity for nitrogen. Any impurity in oxygen made by the electrolytic process will be hydrogen; excess quantities will reduce the flame temperature and of course necessitate the use of more oxygen in the blowpipe. Electrolytic oxygen, however, is generally supplied in a comparatively pure state.

Strength of Weld

The strength of a weld produced by the oxy-acetylene flame is, as a rule, less than that of the original metal unless certain precautions are observed.

This can easily be accounted for. It is rarely possible to obtain for filling-in purpose rods of similar material to that being operated on. It is common practice to use rods of high-grade Norway iron for filling-in. This permits of a sound, soft, homogeneous joint being made, but Norway iron has a low tensile strength as compared with the iron and steels of commerce that have to be operated on. This naturally weakens the weld as regards tensile strength. Tests have been given out from time to time which tended to show that steel plates up to ⅝ inch in thickness could be autogenuosly welded and that the weld was stronger than the original plate. This is impossible unless the material used for filling-in be of higher grade than the plate itself.

A claim of 100 per cent. weld strength is unsupportable. Practice has shown that with thin steel sheets, say, ⅛ inch thick, one can get a weld strength of 95 per cent. and that this figure falls to 85 per cent. for 1 inch thick plates. However, in most cases where welding has to be carried out there is no objection to adding a fillet of metal along the joint or using special high-tensile-strength steel for filling-in, when the welded portion can be made to equal or exceed the strength of the rest of the work.

Skilled Men Needed

Satisfactory results will never be obtained unless skilled workmen are employed to operate the blowpipes. It does not take very long for an intelligent workman to become a fair welder on straight-ahead work on steel plates and similar classes of work which does not exceed ⅜ inch in thickness. To weld metals under ⅛ inch thick requires considerable skill, which practice alone can produce. It takes considerable time for a beginner to attain the necessary steadiness of hand to make a neat weld and avoid piercing the plates. On this class of work buckling difficulties also have to be contended with, but experience soon shows how to overcome them.

Skill in Thick Material

To weld work over ⅜ inch thick takes very considerable skill, and honesty on the part of the operator is indispensable. It is impossible to judge the quality of a weld by merely examining the work after completion—it may have a good appearance and yet be poor work; that is to say, if the plate were fractured at the weld it might be found that the proper fusion had not taken place right through the section and a proper homogeneous mass produced.

The skill necessary to undertake this class of work should be attained after a few weeks' practice. Men employed on it should never be hurried; otherwise poor work will result. Piece-work should never be considered under any circumstances. Welding on thick plates is as a rule connected with work of importance; a faulty weld may have serious results; consequently unless the workman can be trusted, careful watching during the welding process is essential, as that is the only time when the bad work can be detected.

Anyone watching the welding process for the first time comes to the conclusion that the operation is very simple and that any workman can operate the blowpipe with little or no practice. This has been a somewhat serious handicap to the industry, as enthusiasts after seeing the process have purchased an equipment and then without any preliminary practice attempted to use it on work of some importance; of course, failure has been the result in most cases and the blame laid not to the operator but to the process.

Skilled Welder Essential

Oxy-acetylene welding must be considered a trade; a skilled welder is just as much of an artisan as the ordinary blacksmith. This has been appreciated fully in Europe, where welding schools are located at all important centers, and men are thoroughly instructed in the process; after leaving the schools they are placed out on probation in shops where the process is in general use; if, after a period, they have attained the necessary skill they are granted a certificate. Manufacturers will rarely employ a man for welding work who does not hold a certificate from one of the schools.

Cleaning the Parts

One of the chief points to be borne in mind, if oxy-acetylene welding is to be carried out successfully, is that very careful preparation of the work is necessary. The parts to be welded must be free from rust and grease.

When making butt or end-to-end welds on plates, it should be certain that the work is cut true. Plates over ⅛ inch thick must, when a butt joint is desired, be beveled and the opening across the top of the V should at least equal the thickness of the plate so as to make possible the metal being welded throughout the entire thickness of the plate.

Plates over ¼ inch thick should be beveled if possible on both sides; also welded from both sides.

Many workmen will try to weld plates up to ⅜ inch thick without beveling, but a poor joint is invariably the result, mainly due to burning of the metal, caused by too lengthy application of the blowpipe flame.

The welding together of plates of different thickness is somewhat difficult, but not by any means impossible; in most cases where this has to be done some special manipulation can be devised to make the job practical.

Welding Speed

The following table shows the speed at which the welding of steel and iron plates can be carried out; also the necessary acetylene gas consumption:

Thickness of metal Inches	Run Per Hour Feet	Acetylene Per Hour Cu. Ft.
1-32	30	3.25
1-16	25	5.00
3-32	20	8.25
1-8	15	12.00
3-16	9	18.00
1-4	6	25.00
3-8	4	42.00
1-2	3	60.00

The oxygen consumption will be 1.1 to 1.5 times the acetylene consumption, depending on the quality of the blowpipe employed. As would be expected for metal over ⅜ inch thick the gas consumption per foot run of work increases rapidly, and the speed at which the work can be done falls. This leads one to conclude that for constructional work 3-8-inch metal is about the thickest that should be worked, except in cases where older methods, such as riveting, are impossible. For repair work the case is altogether different; metal of any thickness can be worked, and in almost all cases the repairs effected will be made more quickly, better and more economically than by old methods.

Relieve Internal Strains

In every case of welding internal strains are inevitably set up, due to the metal expanding when heated and contracting when cooling. When the parts welded form part of a structure and are restrained during the welding process, the strains produced may cause cracking of the metal, especially in the case of cast iron; and the tendency to crack will be greatly increased if the cooling of the metal, after fusion, is rapid or irregular.

Whenever local strains exceed the strength of the metal, a fracture must occur.

In order to relieve welded metal from internal strains due to welding, it is desirable to preheat the whole work, before welding, and also to reheat it after the welding is completed. In the case of cast iron in a restrained part of a structure this treatment is imperative; the heating should be carried on slowly and the work kept free from air-drafts. This treatment is less essential for steel but can never be anything but beneficial.

Welding Cast Iron

To one not acquainted with the process, the welding of cast iron appears to be more difficult to accomplish than work in steel or wrought iron, but such is not the case. Carbon exists in cast iron, in different states; in what is called white iron, which is very hard, the carbon is combined with or dissolved in the iron, but in gray iron, which is soft and easy to work, most of the carbon is in a free state in the form of graphite. Since it is generally necessary to work a weld in cast iron, it is indispensable that the line of welding be constituted of gray iron.

The obtaining of welds of gray iron depends on the state of the carbon in the metal. Rapid cooling tends to bring about the combination of the carbon and iron, that is to say, the formation of white iron. Slow cooling or reheating after the welding is completed tends to bring about the precipitation of the carbon and the production of a softer material.

It is found by employing silicon in the filling-rod in the form of ferro-silicon, the iron combines with the silicon in preference to the carbon and allows the carbon to take the form of graphite and thus facilitate the formation of gray iron.

The presence of manganese has exactly the opposite effect. It will be seen that in order to get good workable welds there must be slow cooling after the welding is completed. The filling-rod must contain a percentage of silicon, and there must be no manganese present.

Flux for Cast Iron

The welding point of ordinary cast iron is lower than that of iron or mild steel and lower than the melting point of iron oxide; therefore, if any oxides are formed during the welding process they cannot be melted and blown away by the flame as is the case where iron or steel is fused, when this can be done, due to the fact that the melting point of the steel is higher than that of the oxide. It will, therefore, be seen that when welding cast iron it is necessary to employ some flux to break down any oxides formed. When working on thick cast iron the parts to be joined should be beveled as for steel.

Avoiding Breaks

Cast iron is a comparatively poor heat conductor, and has no elasticity or elongation before rupture. It is therefore necessary to appreciate that when welding it expansion and contraction may bring about breaks if the parts oppose free play of the metal, and special precaution must be taken to prevent this. When the size of the piece to be welded allows complete preheating of the whole and slow cooling, breaks or cracks are not to be feared, but with large castings where total preheating is impossible, the welder must exercise thought as to how he can overcome the effects of expansion and contraction by heating other parts of the piece away from the welding point.

The welding of malleable iron is a somewhat difficult and uncertain operation. Malleable castings are supposed to be of the same texture throughout, but in some cases consist of a core of cast iron surrounded by a layer of iron. It will be appreciated that between the surface of the casting which is nearly free from carbon and the core which is cast iron, there exists a more or less carbonized zone. In some cases where castings have thin parts which are properly decarbonized and the fracture is in the thin part, the welding can be carried out just the same as in mild steel. In the thick part of a casting, however, it is different, as the metals of the core and the surface are not the same and require altogether different treatment.

Aluminum Field Large

The welding of aluminum by the oxy-acetylene process provides an enormous field. Those attempting the work for the first time are apt to be discouraged by their failure, which is common until a few little points have been mastered.

The melting point of pure aluminum is about 650 degrees Centigrade, and the metal is very fragile in the near neighborhood of this temperature. It is the low melting point combined with high conductivity and specific heat that makes welding difficult for the beginner. The high melting point of the oxide (alumina) as compared with that of the metal itself has to be contended with also.

To insure good welds the work must be absolutely clean. To remove all traces of oil from an old aluminum casting takes considerable time; this is best done by heating slowly over a charcoal fire and carefully wiping the oil away as it exudes from the metal. The welding or filling-rod employed on pure aluminum must also be quite pure, as the introduction of foreign elements may bring about disintegration along the line of welds.

The low melting point of the metal necessitates skilful manipulation of the blowpipe, although a hot and fairly large flame is necessary on account of the high conductivity. The oxide formed during fusion does not necessarily rise to the surface as it is denser than the metal; it is therefore essential to use a proper flux. It might seem that deformation of castings due to expansion would be difficult to overcome, but such is not the case in practice, as the high conductivity of the metal tends to distribute the heat over the whole mass. When preheating a casting before welding, care should be taken not to raise the temperature to over 500 degrees Centigrade; otherwise it may deform under its own weight.

The welding of aluminum alloys, particularly aluminum zinc, is more important than the welding of the pure metal, as most castings are made of this alloy. The percentage of zinc varies as a rule from 10 to 30 per cent., and copper is generally present in small quantities. It is impossible to know the composition of all aluminum alloy castings that come along for repairs; therefore it is necessary to use a filling material that will be generally serviceable. Rods made up of 88 per cent. aluminum, 10 per cent. zinc, 2 per cent. copper, give good results.

Aluminum alloys are not very ductile; hence trouble from expansion and contraction must be guarded against. Some castings have ribs which tend to produce cracks during cooling and in some cases it may be necessary to cut the ribs to allow for the necessary expansion and contraction. These can easily be welded up later.

Good Work in Copper

Until quite recently the successful welding of copper was considered impossible, but this was due to the fact that welders were ignorant of the disturbing factors which contributed to poor results and took no steps to counteract them. It is easy to make a joint that has the appearance of a good weld, but a full knowledge of the nature of the metal and how it should be treated is required before welds can be made that not merely look good but prove under test to be as strong and malleable as any high-grade copper.

To obtain good results special filling-in-rods must be used; the best results are obtained with phosphor-copper rods which are specially manufactured for welding work. It must not be thought that any phosphor-copper is suitable; the amount of phosphorus must be just enough to do the work required of it and no more.

A good flux to employ when welding copper consists of a mixture of salt, borax and boric acid, but should be used sparingly.

After welding the work should be reheated and hammered along the weld, again reheated, and if possible plunged in water. Copper when heated radiates its heat very rapidly, and as it is also an exceptionally good conductor of heat it is found that the heat of the blowpipe alone when dealing with large masses of copper is not sufficient to keep up the fusion; therefore additional heat supply should be provided and as much of the work as possible covered with asbestos to prevent radiation.

The employment of phosphor-copper as a filling-rod prevents the formation of copper oxide, which in excessive quantities renders a weld extremely fragile and weak, although a small quantity of this oxide is not detrimental and is considered by some to improve the quality of the metal. Molten copper will dissolve hydrogen and carbon monoxide in considerable quantities and when the metal solidifies the gases are evolved. This causes a frothing of the metal in solidification, the resulting metal being spongy. Unfortunately the gases present in the blowpipe flame are those on which copper exerts its solvent property, but the use of phosphor-copper prevents this, the phosphorus either suppressing their solution or aiding their evolution before the metal solidifies.

Copper has a high coefficient of expansion; the consequence is that in cooling considerable stresses may be set up due to contraction, and as coppper has very low tensile strength these, unless counteracted, may cause fractures; but precaution can be taken to prevent this and as a rule the contraction stresses can be nullified by opposing them by means of local heating applied to certain parts, dependent on the shape of the article, or by proceeding with the welding on a certain plan.

Brass Welds Easy

The welding of brass is quite simple, although it would appear at first sight that evaporation of the zinc would be detrimental. This difficulty is overcome by the employment of special welding rods containing a small percentage of aluminum.

A good flux to employ when welding brass consists of a mixture of sodium-chloride, borax, and boracic acid. Hammering of brass after welding considerably improves the metal. It should be done cold on brass with a high percentage of copper, and hot on brass with a low percentage of copper. After cold hammering the brass should be annealed.

Neutral Flame in Bronze

The welding of bronze requires that the welding flame be quite neutral. Special welding rods have to be used, containing a percentage of phosphorus in proportion to the nature of the bronze. A similar flux to that employed in brass may be used. Annealing after welding is essential.

Metal Cutting by Flame

It is probably not out of place to refer to the development of metal-cutting by means of oxygen. The blowpipe used for cutting metals by oxygen generally consists of an oxy-acetylene blowpipe fitted with a central following jet for oxygen only. The work that has to be cut is first of all heated up by means of the oxy-acetylene jet, and as soon as it is raised to a temperature at which oxygen will ignite it, the separate oxygen jet is turned on, and the metal at once burns away very rapidly.

The oxygen supply has sufficient pressure behind it to blow away the oxide as it is formed, with the result that a clean, narrow cut can be made through plates up to 12 inches in thickness and over. The speed at which this work can be done is high, varying from 100 feet per hour for metal 1-4 inch thick to 12 feet per hour for metal 12 inches thick; the oxygen consumed in this process varying from 0.50 cubic feet per foot run in 1-4-inch plates to 50 cubic feet in 12-inch plates.

The users of the oxy-acetylene welding process find it most advantageous to have oxygen-cutting blowpipes in conjunction with their plants. They are found most useful in preparing work which has to be autogenously welded, more particularly in opening out cracks.

Miscellaneous Application

It will be appreciated that the applications of autogenous welding are innumerable when it is considered that it is possible to weld practically almost any commercial metal without in any way seriously altering its nature, and to add at will any metal to any piece of work. The following are some of the applications to which the process is put today:

Repairs to all classes of boilers in place, such as building up wasted landings and corrosion, repairing cracks in flues and patching same. Repairing cracked or broken castings of any metal. Making good castings that come from the sand with blow or sand holes.

It replaces brazing on cycle frames, forks, and wheel rims. The manufacture of small steel boats; substituting riveting. Manufacture of safes; castings impossible to mold can be made in parts and united; artistic ironwork; railway steel car construction and repairs; building up parts worn by friction; pipe jointing; repairs to locomotive frames, cylinders, boilers, etc.; manufacture of steel barrels; manufacture of air and gas containers; filling up holes drilled in error, and many others.—H. SIDNEY SMITH, Engineer of the Prest-O-Lite Co., Inc.

CAROLINA, ALABAMA, GEORGIA, FLORIDA, LOUISIANA	*HEADQUARTERS IN* LOS ANGELES, CAL. PACIFIC SLOPE WEST OF ROCKY MOUNTAINS

The sales organization of the Moon Motor Car Co., St. Louis, Mo., is divided in several districts, all presided over by the sales manager, who reports to the vice-president.

The sales manager of the Eastern district William J. Coghlan, with headquarters in New York City, handles everything east of the Alleghanies and north of the lower Virginia line.

Southeastern sales manager O. M. Graham covers Tennessee, Mississippi, Alabama, Georgia, North and South Carolina, Florida and Louisiana.

Central sales manager J. H. Gibson, who was formerly sales manager of the Hudson company, covers Illinois below a line drawn through Peoria, Missouri, Arkansas and Kentucky. Mr. Gibson makes his headquarters in St. Louis.

Ohio territory is covered by P. J. Eubanks, formerly the sales manager of the Chicago Electric Co., with headquarters in Columbus, and he also handles Indiana, Michigan, West Virginia, western Pennsylvania and western New York.

The northwestern sales manager, J. A. O'Brien, makes his headquarters in Minneapolis. He also covers North and South Dakota, Montana and the northern portion of Wisconsin, as well as such Canadian territory which is tributary to Minnesota, namely Saskatchewan and Manitoba.

Southwestern sales manager, Guy Nunnelly, handles Nebraska, Oklahoma and Texas, and makes his headquarters in Temple, Tex.

The Pacific Coast sales manager, E. N. Sanders, who was formerly manager of the Moon Motor Car Co. of Illinois, in Chicago, but for the past 2 years on the Coast, with headquarters in Los Angeles, takes charge of all the business west of the Rocky Mountains.

In dividing the country like this, the Moon company feels that the introduction of local sales managers and the possibility of getting in closer touch with the dealers answer their requirements more promptly than would otherwise be the case.

Each sales manager has full authority and is empowered to conduct his business without any additional authority,

Saving 7 Per Cent. of Trucks' Time

Study of Boston Freight Terminal Shows This May Be Made By Small Changes—Amounts to 42 Minutes in 10-Hour Day

EDITOR'S NOTE.—*This is an abstract of a paper presented before the New York Railroad Club, entitled, "The Delivery and Handling of Miscellaneous Freight at the Boston Freight Terminals," by Harold Pender, H. F. Thomson and C. P. Eldred. It is copyrighted and all rights are reserved.*

THAT a saving of 7 per cent. can be made in the working day of the trucks using the railroad freight terminals in Boston is the conclusion drawn in a paper presented to the New York Railroad Club, at the monthly meeting Sept. 18, 1914. In a 10-hour day this amounts to 42 minutes, and this, coupled with a somewhat greater possible reduction at the warehouses in loading and unloading, shows that the amount of useful work a truck may do can be largely increased. This reduction is of more importance to the economical operation of motor trucks than of horse-drawn ones because of the greater speed of the former. In fact, this fact might, under certain conditions, make it more profitable to operate motor trucks, where before it had been cheaper to use horse trucks.

This 7 per cent. of the total working day represents 18 per cent. of the time spent in the freight yards. The time lost may be divided up into several parts. Waiting for a place at the freight house doors to load or unload causes some loss, especially during the rush periods in the early morning and late in the afternoon. At these times the yards are crowded with vehicles, while at other periods of the day they are comparatively empty. Some time is lost in searching for freight and calling at doors without loading. A large part of this time can be saved by simple changes in the clerical work. Closer co-operation between the drivers and the railroad employees would reduce the time in loading and unloading. Contrary to expectation, very little time is lost by the loafing of the drivers, and the small amount of time the drivers do waste is chargeable to the extremes of weather. Better pavements would reduce the time a small amount, especially in bad weather, and so would better location of the various freight houses.

This paper, entitled, "The Delivery and Handling of Miscellaneous Freight at the Boston Freight Terminals," was prepared by Harold Pender, H. F. Thomson and C. P. Eldred, and was the result of an investigation of freight conditions around Boston extending over a year. The investigation was started by the Electrical Engineering Department of the Massachusetts Institute of Technology in the Spring of 1912, when several students made a number of observations on the movements of all kinds of vehicles at the Boston freight terminals. This resulted in two railroads contributing $2,000 jointly for the appointment of a research assistant, and during the past year he has devoted his entire time to this work, under the supervision of the Research Department of the Electrical Engineering Department of the Institute.

This study was made because of considerable criticism, from time to time, on the part of the shippers, and truck drivers of the terminal facilities and of the methods employed by the railroads in sending out notices, and in delivering freight, particularly, less than car load lots, or L. C. L. shipments as railroad men are accustomed to calling them.

Before considering the conclusions drawn in this paper in detail, an understanding of the system of handling freight must be had. There are three railroad freight terminals, as shown by the map of the city, Fig. 1. The N. Y., N. H. & H. is represented by the five blocks in the lower right-hand corner which represent eleven freight houses and two piers. The two small blocks to the west of the South Station (Boston Terminal) represent the four freight houses of the Boston & Albany railroad. The string of blocks on the upper part of the map to the north and west of the North Station (Union Station) represent the thirty-five freight houses of the Boston & Maine.

The New Haven's terminal, the Boston & Albany terminal and one division of the Boston & Maine are each approximately 1 mile from the center of the city.

The study has been confined to the handling of loads of less than one car.

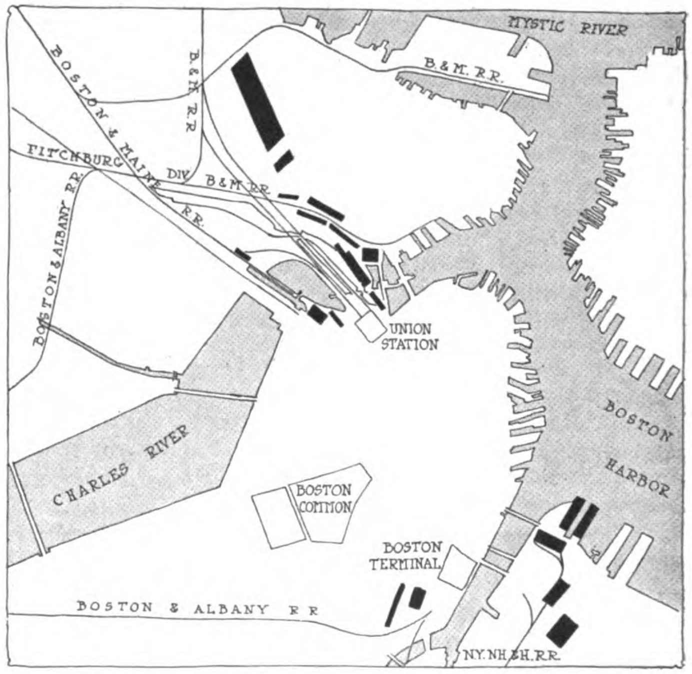

Fig. 1—Boston, showing freight terminals of the three railroads

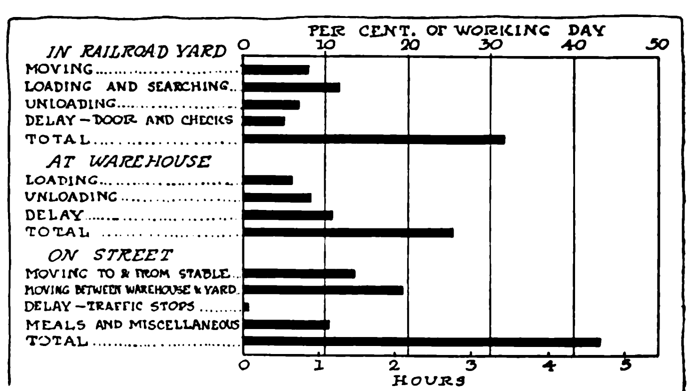

Fig. 2—Analysis of performance of eight wagons during 8 days

Inward and outward shipments are generally handled through separate houses. At the inward freight houses the driver must locate and load his freight. He first receives, at the cashier's office, a delivery check which designates the house and usually the door at which the freight will be found. After arriving at the door, he must pick out his freight and load it. In case the teamster finds freight in the house for which the delivery check is not available, he may load it upon obtaining a memorandum check from the cashier.

At the outward houses the teamster must distribute his freight at one or more doors according to its route and destination. Then he obtains a receipt from the railroad.

The New Haven and the Boston & Maine issue loading books which state the house and door number at which the freight will be received, but generally the truck drivers are allowed to unload at any door in the immediate vicinity of the one specified. This tends to avoid congestion and also to make it unnecessary for a teamster to move his wagon from door to door in case he has freight for several points normally unloaded at doors near one another.

The regular delivery check for each consignment is made out in the freight agent's office from the waybill, the latter either coming with the consignment or by mail. The delivery check is then sent to the cashier's office and the proper door number is written on it as soon as the information is received from the delivery clerk in the freight house. The check is then put into a pigeon hole near the window of the cashier's office, where it is available when the teamster calls for it.

The Memorandum Check

The system of using memorandum checks referred to is to enable consignees who expect freight to obtain it as soon as it is placed in the freight house, without waiting for the regular delivery check to be filed. A teamster is permitted to enter the freight house and look for such freight, knowing approximately where it is likely to be located. After finding it he may go to the cashier's office and obtain a memorandum check and the freight will be surrendered by the delivery clerk on presentation of this check. This system, although it requires the driver to spend more time at the freight house, is of considerable advantage to consignees in case of error.

In conducting the test, the first point determined was the percentage of time spent in the yards by one and two-horse trucks. It was found that these spent approximately one-third of the day in the yards. This is shown graphically in Figs. 2 and 3.

After this it was determined that the delay per day at the warehouses, or stores was actually greater than the delay due to the congestion in the railroad yards. Observation on 700 loads showed that the average delay at the warehouses was 38 minutes, as against 29 minutes at the yards. These were for two-horse wagons composed chiefly of goods packed in barrels, and averaging slightly over 4 tons.

In another case observations on two and three-horse wagons showed that an average of 51 minutes elapsed between the arrival and departure of the trucks at the warehouse. Of this time, only 16 minutes were spent in loading, the remaining 35 minutes being consumed in waiting for a turn at the loading platform. This fault was due chiefly to poor assignment of the wagons, more being used than could advantageously be employed under the conditions.

The relative times spent by the different types of vehicles in visiting a given freight house or group of houses is indicated graphically in Fig. 4.

Inward Peak at 9 A. M.; Outward, 5 P. M.

The number of vehicles calling at the outward and inward freight houses throughout typical days was also observed, and the results were plotted, Fig. 5. The peak of the inward traffic occurred at 9 a. m. and the peak of the outward traffic at 5 p. m. The relative volumes of traffic are proportional to

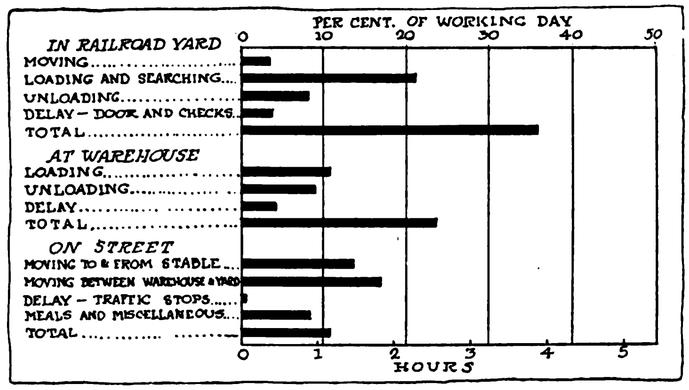

Fig. 3—Analysis of daily wagon performance based on 13 days' observations on four wagons

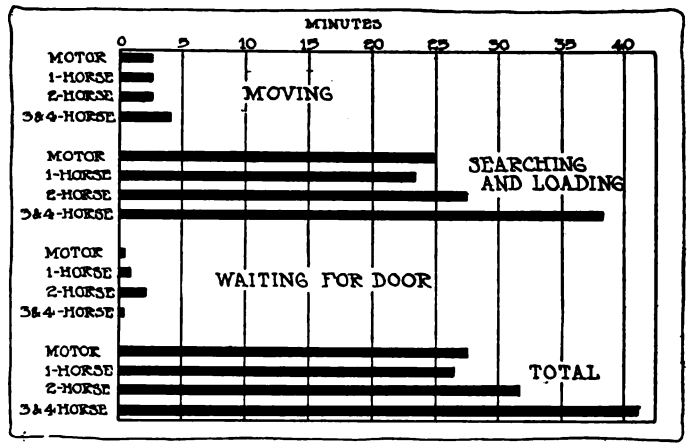

Fig. 4—Times spent per vehicle at inward freight houses

the areas under the curves. These curves show that about 30 per cent. of the total inward traffic is between 7 and 9.30 and that about 35 per cent. of the outward traffic occurs between 4 and 5.30. These curves show that one of the greatest difficulties encountered by the railroads is the necessity of providing facilities which are utilized to their maximum capacity during only 1 or 2 hours per day.

1.1 Minutes Waiting for Turn

Further observations showed that time lost in waiting for one's turn averaged 1.1 minutes during the afternoon, traffic being heavier then. On the average, each vehicle made 3.5 calls per trip at the outward houses, the total delay thus resulting being 3.5 times 1.1, or 4 minutes.

Similar determinations at the inward freight houses showed that the average wait per door was .6 minute, and that the average door calls were 2.5 per trip. Therefore, the average wait was 1.5 minutes.

The time spent in waiting for a turn is the only lost time chargeable to the railroads at the outward houses. At the inward houses, however, there may also be a delay due to three causes: inquiries at the cashier's office; loafing of the driver; searching for freight by driver.

An analysis of the total time spent by trucks at the inward freight houses is given in Table I, page 892.

Inquiries at Cashier's Office

Six per cent. of the total time spent in the freight yard is consumed in making inquiries at the cashier's office. This time is spent chiefly in obtaining memorandum checks for shipments whose delivery checks are not available, and correcting errors on delivery checks as discovered by the driver. As a large proportion of the calls are for memorandum checks any improvement in the handling of freight that would render these unnecessary would result in a time-saving.

Time spent by the driver in loafing about the cashier's office was found to be an appreciable item, especially on very

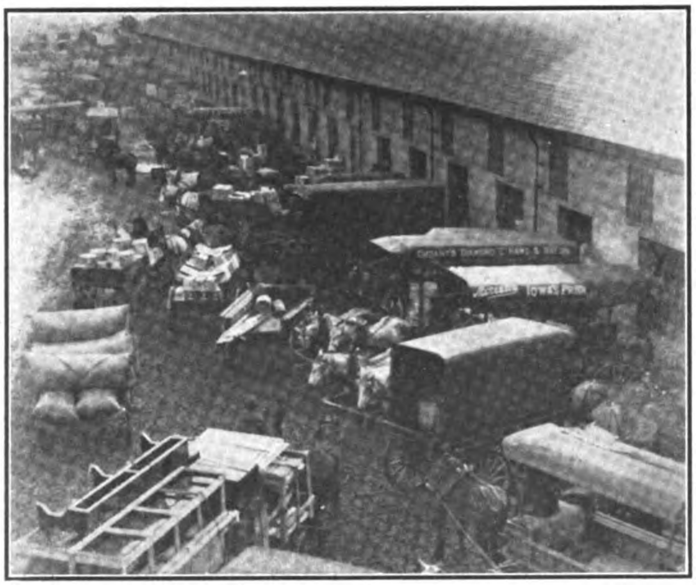

Fig. 5—Illustrating the congestion in the freight yards early in the morning and late in the afternoon

TABLE I.

ANALYSIS OF TOTAL TIME SPENT BY WAGONS* AT INWARD FREIGHT HOUSES

Number of wagons observed	88
Average number of house calls per yard call	1.3
Average number of door calls per yard call	1.8
Average number of pieces per wagon	23
Average weight per piece, in pounds (approx.)	120

Item	Av. time per wagon in freight yard	
	Minutes	Per Cent.
CASHIER'S OFFICE:		
Checks	3.8	8.1
Inquiry	2.8	6.0
Loafing	1.9	4.1
	8.5	18.2
FREIGHT HOUSE DOOR:		
Giving receipt and making inquiries of Delivery Clerk	2.2	4.7
Searching (including calls without loading)	4.1	8.9
Loading	16.2	34.8
Delay at door	0.5	1.0
Helping other drivers	1.0	2.1
Roping, etc	2.3	4.9
Loafing	1.6	3.4
	27.9	59.8
Moving in Freight Yard	10.3	22.0
Total	46.7	100.0

*These wagons on the average carried somewhat lighter loads than those on which the data given in Figs. 2 and 3 were obtained.

TABLE II.

ESTIMATED DISTRIBUTION OF TOTAL TIME IN YARD FOR AVERAGE TWO-HORSE WAGON

(Wagon receiving freight calls on the average at 1.5 houses and at 1.5 doors per house. Wagon delivering freight calls on the average at 2 houses and at 1.75 doors per house.)

Distribution of time	Time in yard for wagon to obtain load, minutes			Time in yard for wagon to deliver load, minutes		
	Present	Possible reduction by railroad	Net time after reduction	Present	Possible reduction by railroad	Net time after reduction
Obtaining checks	4	..	4	..	..	..
Receipts and inquiries	5	2	3	..	..	..
Waiting for door	1.5	..	1.5	4	1	3
Searching for freight, including calls without loading	8	5	3	..	..	..
Loading or unloading	35	5	30	25	4	21
Loafing	3.5	..	3.5	..	..	..
Moving in freight yard	10	1	9	10	1	9
Total	67	13	54	39	6	33

cold or hot days. The average loafing time in December, March and April was 7 per cent. of the time in the yard.

The average time spent in searching for freight was 9 per cent. of the total time, or 15 per cent. of the time at the freight house door. In some instances this time was spent in locating freight for which the delivery check was not available, and which the driver wished to make out a memorandum check for. A part of the searching was caused by the crowded condition of the houses, but the chief causes were the scattered consignments and neglect to place the pieces of freight so that the identification marks could be read easily. In some cases searching was indirectly due to the poor manner in which the goods had been packed and marked by the shipper—in the rehandling packages had become so battered that the addresses were almost unrecognizable.

It frequently occurs that a consignment of goods billed in one car will arrive in several cars and will therefore be scattered over the freight houses when unloaded. The remedy for this lies at the point of loading.

In many cases it was found that a wagon would call at a door and leave it without loading any freight, and observations showed that the time thus spent averaged 1.7 minutes per call. These delays were due to errors on the delivery checks and errors by drivers. In certain cases the omission of the door locations arose from the fact that the office work was ahead of the yard work and the drivers preferred to obtain the delivery checks without locations designated, and to search for the freight. Errors on the delivery checks were due to carelessness in making out the checks, to illegibility of the waybills from which the checks were made, or to the shifting of a car before it was unloaded to a position other than that reported to the cashier's office.

The above observations and the times which might be saved are summarized in the accompanying Table 2. No additional houses nor any radical change in equipment would be required to carry out these suggestions.

According to this estimate 13 minutes may be saved from the time now spent in the yards to obtain a load, while 33 minutes may be cut from the time consumed in unloading.

Obtaining Checks

This item includes the time spent by the teamster at the cashier's office in obtaining delivery checks and settling bills. The time of 4 minutes could not be reduced.

Under this head comes the time spent by the driver in making inquiries at the cashier's desk, in telephoning about lost shipments, in giving receipt to the delivery clerk and in making inquiries in the freight house. This time of 5 minutes could be reduced by greater care in making out the delivery checks, which in turn are often due to errors in the waybills. Errors in both could be reduced if the practice of making them out on a typewriter were universal.

This item was found to be surprisingly small, only 1.5 min-

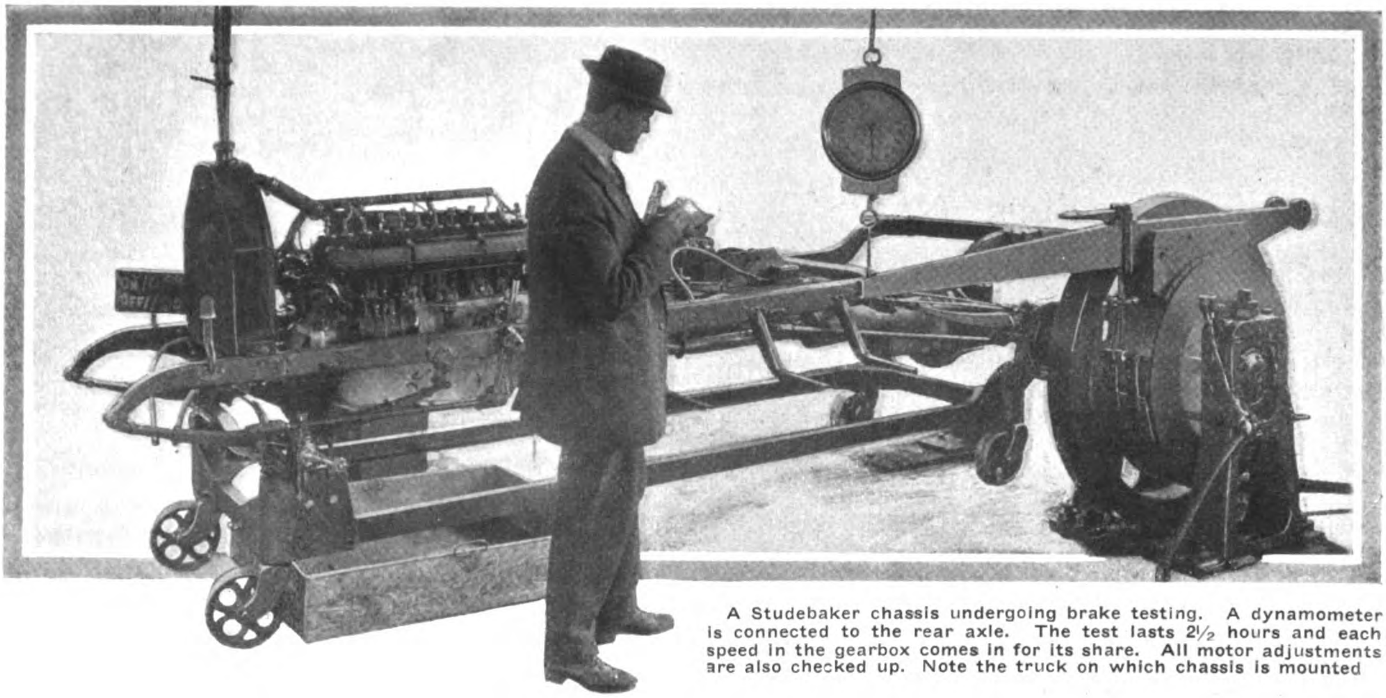
Studebaker Tests by Dynamometer



A Studebaker chassis undergoing brake testing. A dynamometer is connected to the rear axle. The test lasts 2½ hours and each speed in the gearbox comes in for its share. All motor adjustments are also checked up. Note the truck on which chassis is mounted

IN a long, narrow building the Studebaker Corp., Detroit, Mich., has installed nineteen dynamometer testing stands for trying out the new chassis as they come from the assembly departments. Along the 300 feet of length there are water mains for supplying radiators from a main tank, gasoline mains for providing motors with fuel and dynamometers for registering the power developed.

For 2 1-2 hours each chassis is run under load in this department before it can further advance in its journey to completion. Coming to the testing room on a form of iron truck which has been its steady companion ever since assembly began, the chassis is pushed to a test stand and made ready for work. At the back of the stand there is a substantial clamping arrangement which attaches to the rear axle housing and holds the chassis securely in place. A special axle shaft with an outer end arranged to couple to the dynamometer shaft is slipped into the axle, taking the place of the regular axle shaft, its inner end being splined to slip into the differential just as the regular shaft does. Fifty cars are tested per day.

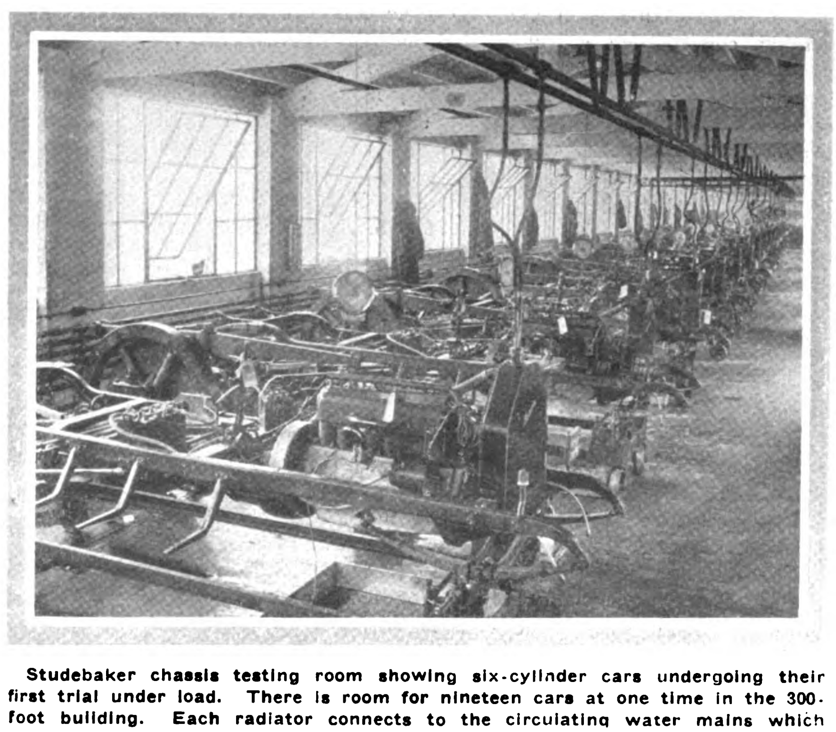
Previously, the motor and rear axle have been tested separately in their respective assembly departments. The lowest grade of gasoline is used to insure satisfaction under all conditions.

The procedure in giving the chassis its 2 1-2 hour test insures that each speed reduction in the gearbox is satisfactory as well as all other features. The first step is to throw in the reverse, for 15 minutes. The load put on the prony brake is 85 pounds, which corresponds to about 42 horsepower.

Then the first speed gears are thrown in, and the car operated for 30 minutes pulling about the same load of 42 horsepower. It is next put into second speed and run for an hour. The first 30 minutes of this second speed run the load is light, perhaps around 20 horsepower, while the last half hour is a heavy pull at about 42 horsepower.

Finally comes the run in high gear. This lasts 45 minutes, the load corresponding to a setting of 55 pounds on the brake. This amounts to from 27 to 30 horsepower load.

During these various runs, the testers watch the performance and make any adjustments which are necessary. They look for oil and water leaks, adjust the tappets and the ignition timing and check up the performance of the carbureter. After a rigid inspection the car goes to the paint shop.



Studebaker chassis testing room showing six-cylinder cars undergoing their first trial under load. There is room for nineteen cars at one time in the 300-foot building. Each radiator connects to the circulating water mains which communicate with a tank. The gasoline is also supplied to each chassis from a main pipe

Reader Describes New Two-Cycle Motor

Editor The Automobile:—I have been reading with interest various articles published by you in The Rostrum, referring to two-cycle motors, and would like to get a little information regarding the following:

Since the Elmore and Amplex companies have gone out of business, do any other automobile manufacturers in the United States use a two-cycle motor?

I am very much interested in the development of a two-stroke motor as I am about to receive a patent on one that does not use the crank case as a compression chamber but primarily compresses the charge by a means provided for this purpose on the power stroke of the piston and delivers this charge automatically to a port located in the side of the combustion chamber at or near the top of same, this delivery occurring about the end of the power stroke.

The exhaust port at the base of the explosion chamber is closed by the return of the piston and the inlet port at the top of the explosion chamber is closed by the upward movement of a tube which answers both the purpose of a circular slide valve and a means to convey the primarily compressed charge to the inlet port in the explosion chamber. This tube is provided with expansion wings to prevent the escape of both compressions, that is, the compression in the primary chamber and the compression in the explosion chamber. The tube operates in conjunction with the compression means.

This motor can be used either as a two-stroke or a four-cycle motor. When used as a four-cycle a charge is admitted to the compression chamber only on every other suction stroke, air being taken in each alternate suction stroke. For two-cycle action, gas is admitted every suction stroke. This motor will be positive in action and can be used with a single combustion chamber or it can be used as a unit to make up any number of cylinders desired.

Pittsburgh, Pa. Karl E. Dunbar.

—The Duryea, made by the Cresson-Morris Co., Eighteenth street and Allegany avenue, Philadelphia, Pa. and the Chase truck manufactured by the Chase Motor Truck Co., Syracuse, N. Y., are the only two makes of note in the United States using the two-cycle motor.

Italian Fiat Co. Makes Two Fours

Editor The Automobile:—1—Please give me a brief description of all Fiat models made at the present time in Turin, Italy, but not made in Poughkeepsie.

2—Please give me the price and mechanical description of Crane cars. How many are made in a year, and by whom?

New Jersey. S. Roebling.

—1—Two chassis are now built by the parent Fiat company in Turin, Italy. One is a 20/30 horse power model selling for $3,200, and the other is rated at 30 horsepower and sells for $3,750. The former is strictly a town car chassis and will turn in a 25-foot circle. It has a block motor 3.2 by 5.6 inches, and a pressure oiling system. The magneto is a Bosch and the carbureter is a special Fiat multiple jet type. The clutch is a multiple disk, the gearset has four speeds, and the rear axle is a pressed steel type. The foot brake is a worm-operated contracting type and the hand brake operates internal expanding drums on the rear wheels. The wheelbase is 110 inches and the tread is standard. Equipment includes two multiple-bulb headlights, electric horn, electric starting and lighting, toilet cases, and demountable steel wheels. The price of this chassis fitted with either coupé or landaulet body, is $4,700. The latter is shown in Fig. 1.

The specifications of the 30 horsepower light touring car chassis are much the same, except that the motor measures 4 by 5.5 inches, and the wheelbase is 116 inches, instead of 110. This car, Fig. 2, is priced at $3,750 with touring body.

2—These cars are no longer made.

Car Tracks Versus Cobbles for Economy

Editor The Automobile:—Which is the smaller expense, driving the car on car tracks to save the mechanism, and thereby wearing out tires, or driving the car on cobblestones in order to save the tires, regardless of the mechanism?

Baltimore, Md. Eldred B. Quarles, Sr.

—This point has never been tested, as far as we know. The motorist should use his judgment in this matter. In some cases, more harm might be done to the car by driving it over rough roads than if the car were run in car tracks to avoid the rough spots.

In other cases it is a question of comfort rather than economy. Many motorists would rather injure their tires a small amount by driving in car tracks than experience the discomfort of rough roads.

How Parabolic Reflectors Are Made

Editor The Automobile:—Will you kindly describe the process or method employed in shaping and polishing the

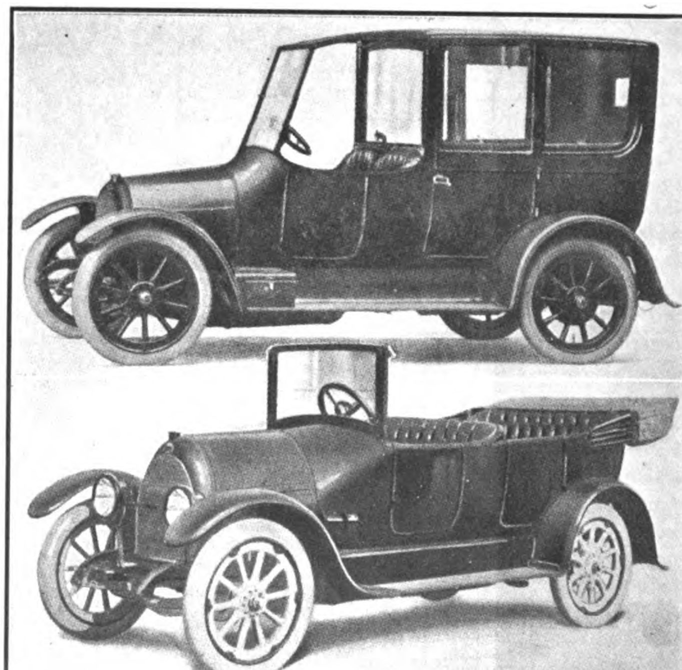


Fig. 1—Upper—Fiat 20/30 horsepower landaulet. Fig. 2—Lower—30 horsepower touring car

best parabolic reflectors such as are used in headlights and searchlights?

2—Is the parabolic form maintained throughout the reflecting surface of the ordinary parabolic automobile headlight?

Pittsburgh, Pa. I. D. W.

—1—According to Gray & Davis, Boston, Mass., parabolic reflectors are manufactured as follows: A special brass is used which gives a very fine surface. This is blanked and formed in hardened steel dies to approximately the shape of a true parabola. Then it is again placed between dies and stamped to give it a perfectly true surface. After this it is ground to a perfect surface, then buffed and finally plated with 99 per cent. pure silver. After plating it is polished.

2—Yes.

How to Calculate Miles Per Hour

Editor THE AUTOMOBILE:—Will you kindly give a simple method of calculating the speed in miles per hour when the time per mile is known?

Newcastle, Ind. E. W. H.

—You may use the formula $M = \frac{3,600}{S}$ where M = miles per hour and S = the time per mile in seconds. This formula has been plotted in the form of a curve in Fig. 3.

The derivation of this formula is a simple matter. S represents the time per mile, or another way of saying it is S = seconds per mile. Now, if M = miles per hour, $\frac{M}{3,600}$ = miles per second, since there are 3,600 seconds in 1 hour. Therefore, $\frac{3,600}{M}$ = seconds per mile, but the seconds per mile is also equal to S. Therefore, $S = \frac{3,600}{M}$. It will be noted that the expression per, in the above derivation is merely a division sign. Seconds per mile may be written seconds ÷ miles, or $\frac{\text{seconds}}{\text{miles}}$; miles per hour may be written miles ÷ hours, or $\frac{\text{miles}}{\text{hours}}$, etc. An understanding of this point will make the above derivation clear.

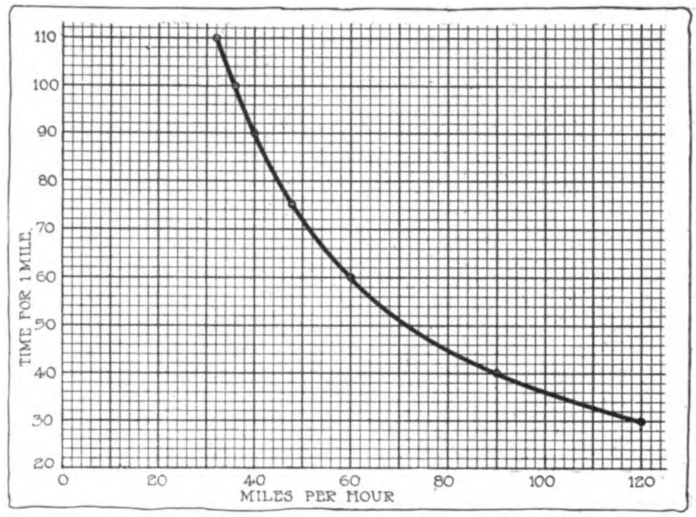

Fig. 3—Curve showing relation of miles per hour and time per mile

Dirt Causes Miss at High Speeds

Editor THE AUTOMOBILE:—As an interested reader of your Rostrum I would like to ask you for some information that I seem to be unable to obtain elsewhere.

1—I have a 1914 ——— and have had a lot of minor trouble with it. At present I find that at low speeds it runs smoothly and with ample power, but if I try and rush a hill, attaining a speed of over 30 miles per hour the motor begins to miss frightfully until it will at last stop altogether. The miss seems to start on one cylinder, increasing to three. The same seems to occur when I run at high speed on the level. A Mayer carbureter is used with Atwater-Kent ignition. The timing seems to be right and the carbureter is adjustable from the dash, so that is all right. I know the gasoline line is clean, and have a hot air attachment to the air intake. What is the trouble?

2—Exclusive of the Chicago Auto Painting Co., who would make a coupé body for this car, which is a runabout?

3—What would be the best way in which to strengthen the engine bed? I find that the motor rocks violently when pulling hard. The bolts holding it to the bed are tight and the bed vibrates with it.

4—The water circulation seems to be defective. After running but a short distance the water becomes steaming hot. This occurs before I have gone a mile. If the distance is very far the water boils. The cylinders are clean and the timing is correct. I have flushed out both the radiator and engine, so there is no stoppage. Can you suggest any way of correcting this trouble?

Orange, N. J. M. S. BALDWIN.

—1—Notwithstanding what you say it would seem that the missing was due to dirt in the gasoline line. The obstruction does not block the line entirely, but enough to prevent an adequate supply of fuel being given to the motor at all except low speeds—hence the missing above 30 miles per hour. Disconnect the gasoline line at the carbureter, and allow the gasoline to run out. If it does not flow freely clean the pipe and outlet from the gasoline tank.

2—Any body making concern will build a body to order for this car.

Hard to Strengthen Bed

3—It is next to impossible to strengthen the engine bed without putting in a new crankcase. Possibly your trouble is due to allowing the motor to pull too hard. When it begins to labor on a hill, shift to low gear. Do not strain the motor by allowing it to work under these conditions.

4—If the timing is correct and the water passages are free there is no reason why the water should boil unless the mixture is too rich or the cylinders are carbonized. Examine the timing and the carbureter adjustment once more, then inspect the cylinders to see whether they are carbonized, and look at the passageways to see that they are not clogged. Even if the radiator is free from obstructions and the hose connections are clear, there may be dirt or sand in the water jackets. Lastly, make sure that water is not being lost, either by leakage or by flowing out through the radiator vent pipe. Sometimes the vent opening is placed low, with the result that the water splashes out until enough has been lost to prevent proper cooling. To keep the water from boiling, the radiator must be full or nearly full at all times. A shortage of water reduces the amount of cooling, and when the level of water drops below the top of the return connection to the radiator, circulation stops entirely.

Six as Fast as Four

Editor THE AUTOMOBILE:—Please explain in the Rostrum why it is that a six-cylinder car will run faster than a four. It is a general impression among people not very familiar with cars that a six is faster, but you never have heard of a six-cylinder car winning a big race.

Greensboro, N. C. E. C. KING.

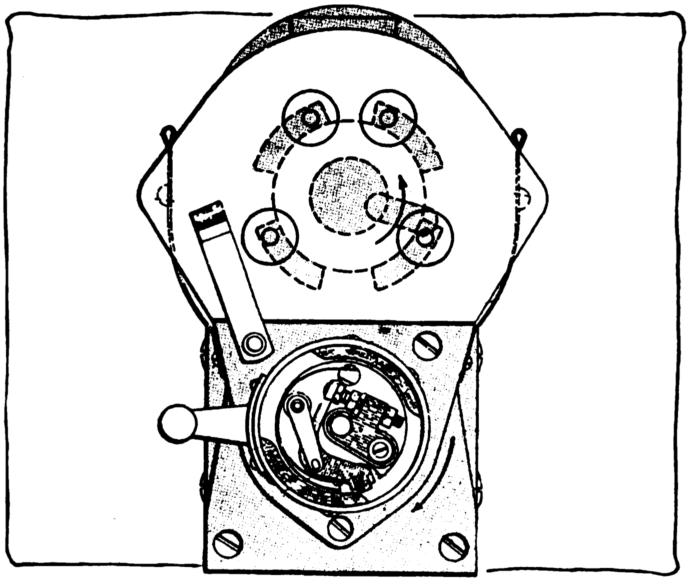

Fig. 4—Bosch DU 4 magneto showing setting for anti-clockwise rotation

—The number of cylinders has very little to do with the speed. One-cylinder cars have done considerably over 70 miles per hour, while twelve-cylinder machines have traveled about 2 miles per minute. So far as the motor is concerned, the speed of the car depends on the power the motor develops, and the number of cylinders influences this only indirectly. If it takes 60 horsepower to drive a car 70 miles per hour it does not matter much how many cylinders the motor has as long as the requisite power is supplied.

Contrary to your statement, six-cylinder cars have won some big races, although four-cylinder machines have won the majority of races, principally because the four-cylinder type preponderates.

Four-cylinder motors have generally been preferred for racing to motors with more cylinders because they are less complicated and there are fewer parts to get out of order, and because few of the advantages of the six which are evident in touring car work have weight in designing racing cars. The six has a smoother torque, less vibration at low speeds, and is more flexible than the four, but as racing motors operate at excessive speeds these points are of no advantage.

How to Change Magneto Rotation

Editor THE AUTOMOBILE:—1—I have a Bosch high-tension magneto, D.U.-4, which runs clockwise, and I would like to reverse it so it will run anti-clockwise. Will I have to send it to the Bosch factory to make this change, or can I do it myself?

2—Please give me details on timing model 27, 1910 Peerless motor.

Huntington, W. Va. W. D. A.

—1—You may do the work yourself, although it would be better to send the magneto to the Bosch factory. The present breaker will have to be changed for an anti-clockwise one and the relation between the armature and distributer shafts will need to be readjusted. In case you do the work yourself, after you have put the new breaker in place, with the spark advanced all the way and the points just ready to separate, set the distributer gear so that from one-half to two-thirds of the width of the distributer brush is still on one of the distributer segments. This relation is shown in Fig. 4, the arrows showing the direction of rotation. This setting is exactly opposite to that for clockwise rotation.

2—You do not state whether you mean the timing of the valves or the magneto. The setting of the former is easily done according to the marks on the flywheel, so that it is probable that you mean the latter.

With the spark retarded all the way, bring the number one cylinder to dead center on the compression stroke, as indicated by the center mark for cylinders 1 and 4 on the flywheel. Then set the armature of the magneto so that the breaker points are just ready to separate.

How to Apply a Cone Clutch Facing

Editor THE AUTOMOBILE:—I have a leather faced cone clutch and wish to put on a new leather one. I want to know the best kind of leather I can get to put on there. I also want a little information concerning the putting on of the leather. I thought perhaps asbestos would be better than leather, and would like to have your opinion on this matter.

Kutztown, Pa. J. F. ANGSTADT.

—Either leather or an asbestos fabric may be used with satisfaction. If you use leather you should obtain friction leather, which is made for this purpose. This may be purchased at any supply store or the following concerns, taken from the Automobile Trade Directory: Chicago Belting Co., 113 N. Green street, Chicago, Ill.; Detroit Leather Specialty Co., 275 Beecher avenue, Detroit, Mich.; Hide, Leather and Belting Co., Indianapolis, Ind.

In ordering the facing the diameters of the two edges of the cone and the width of the cone should be given. If an asbestos fabric is used, care should be taken to obtain a piece that is made for the size of cone you have. Unlike leather, strips of this material to fit cannot be cut from a large piece of fabric.

The thickness of the facing is important because too thick a facing will prevent the cone from properly entering the flywheel. One-quarter inch is an average value.

If you desire to buy a piece of leather and cut your own facing you should remove the old clutch leather carefully and use it for a pattern. Another method is to wrap a strip of paper around the face and make a pattern from it.

Before applying the leather it is well to soak it in a neatsfoot oil to soften it.

Care should be taken to cut the strip of leather to the correct length. The best way is to first rivet one end and then wrap the leather around the cone in such a manner that it slips down over the smaller end of the cone as shown in Fig. 5. Then pull it tight and rivet the other end. Now push the leather up in place all around and it should be tight and unwrinkled. If an attempt is made to apply the facing by attaching the leather to one end only, there is danger of it wrinkling, especially if the leather is not of even thickness. Any unevenness may be removed by truing in a lathe but if the leather is properly put on this should not be necessary.

The same advice applies to putting on an asbestos fabric, but there is less danger of the facing wrinkling.

Special copper rivets designed for riveting leather should be used. These have broad flat heads of medium thickness as shown in Fig. 6. Rivet holes should be cut in the leather and these should be countersunk, as shown. Riveting will be facilitated if a bolt the same diameter as the rivet head is used as a support, as shown in this figure. The round end of the bolt forces the head of the rivet into the countersunk hole and makes a good fit.

80 Per Cent. of Motors Block Cast

Editor THE AUTOMOBILE:—1—How many manufacturers are making motors with cylinders cast separately, and how many are making motors cast en-block?

2—Which are the best and why are they the best?

3—What kind of roller bearings would you recommend as the best?

4—Which style of valves would you recommend as the best for service and silence in the life of a motor, and why would you recommend that kind?

5—What type of rear axle would you say was the most durable and accessible for the ordinary man to use, and also the safest, and why is it the best?

6—Where would you consider the proper place for a gasoline tank.

Bridgetown, N. J. E. R. K.

—1—Considering only the principal makers, the methods of casting the cylinders employed by them is given in the following table:

Type of casting	Percentage
Six cylinders in a block	15.1
Six cylinders cast in threes	17.2
Six cylinders, cast in pairs	16.4
Six cylinders cast singly	1.3
Four cylinders cast in a block	24.7
Four cylinders cast in pairs	22.2
Four cylinders cast singly	3.1

2—What is best under one set of conditions may not be so under a different set. It is impossible to say that a given type of casting is best without restriction. This is proved by the fact that all types of castings are still in use. However, from the above figures it will be noted that the block casting is by far the most popular 15.1 per cent. of the sixes and 24.7 per cent. of the fours being of this type, the total being approximately 40 per cent. The advantages advanced in favor of this type are that it gives a simpler casting, is cheaper to manufacture, is more rigid, and gives the motor a simpler exterior because a large amount of piping is done away with. Against this type it is urged that in case a casting proves defective the loss is greater, two men are required to remove or replace the cylinder block, and should a cylinder become cracked through the freezing of the cooling water, it is necessary to put in four or six new cylinders, as the case may be, instead of one or more if the cylinders are cast singly or in pairs. The advocates of the block method of casting meet these objections with the argument that these faults are actually small in practice.

3—It is impossible to answer questions of this character. As has been said many times before, in order for us to state, with fairness, what make of bearing is best, we would be obliged to test every make of roller bearing on the market exhaustively. In matters such as these we cannot rely on the statements of others because they are liable to be biased. Obviously it is impossible for us to test all makes of bearings.

Each type has its advantages, and by study you can determine the one most suitable under a given set of conditions. In some places adjustable bearings are indispensable, while in others they are not so necessary. Sometimes the decision depends on the price rather than on the quality.

4—Any well-designed poppet or sleeve valve will give good service. It is generally considered that the sleeve valve is slightly quieter than the best designs of poppet valve motors. This difference is small, however, in the best motors of each type. Valve-in-head motors are generally more powerful than the other poppet types, but the mechanism is slightly more complicated.

5—Everything else being the same the durability of the axle is not greatly affected by the type, whether floating, semi-floating, three-quarter floating, etc. The floating axle is somewhat easier to take apart than the other types, but this is a small matter because the axle should not require taking apart very often. From a safety standpoint all are about equal.

6—This depends on conditions; there are advantages in every location. If placed under the cowl, the gasoline can flow by gravity to the carbureter, yet the carbureter does not need to be placed as low as when the tank is under the seat. By locating the carbureter higher, it is more accessible and the intake pipe is shortened, giving better carburetion. The gasoline is warmed by the heat of the motor so that in cold weather, at least, carburetion is facilitated.

The under-seat location of the tank also allows fuel feed by the simple gravity method, but there is danger of the flow stopping when climbing a steep hill. When the tank is being filled, the passengers in the front must be disturbed.

Putting the tank at the rear utilizes otherwise waste space and allows the space under the front seat and under the cowl to be used for other purposes. There is a slight objection to this location, however, because the gasoline must be fed to the carbureter either by pressure or the vacuum system. This means a slight amount of complication, but it is not serious as is indicated by the fact that the majority of cars now use one or the other of these systems.

Net Weights of Various Cars

Editor THE AUTOMOBILE:—Will you please state the weights of the following cars: Saxon, Chalmers, Overland, Metz, Ford, Maxwell, and Studebaker?

Jamestown, Mo. R. H.

—The weights of the different models of the makes you mention are given below. The figures are those claimed by the manufacturers and are with tanks empty.

Saxon	1,150
Chalmers Master Six, five-pass. touring	3,935
Chalmers Master Six, six-pass. touring	4,046
Chalmers Master Six, torpedo	3,928
Chalmers Master Six, roadster	3,792
Chalmers Master Six, limousine	4,439
Chalmers Master Six, coupé	3,996
Chalmers Little Six, five-pass. touring	3,534
Chalmers Little Six, couplette	3,522
Overland, 80	2,900
Overland, 81	2,600
Metz	1,150
Ford, roadster	1,395
Ford, touring car	1,510
Maxwell, roadster	1,800
Maxwell, touring car	1,820
Studebaker Six, five-pass. touring	2,865
Studebaker Six, seven-pass. touring	2,930
Studebaker Four, three-pass. roadster	2,350
Studebaker Four, five-pass. touring	2,425

Ward Leonard Makes Starters

In THE AUTOMOBILE for October 29 on page 805, in giving a list of various starters which might be used on a model 25 Buick, the starter made by the Ward Leonard Electric Co., Bronxville, N. Y., was omitted.

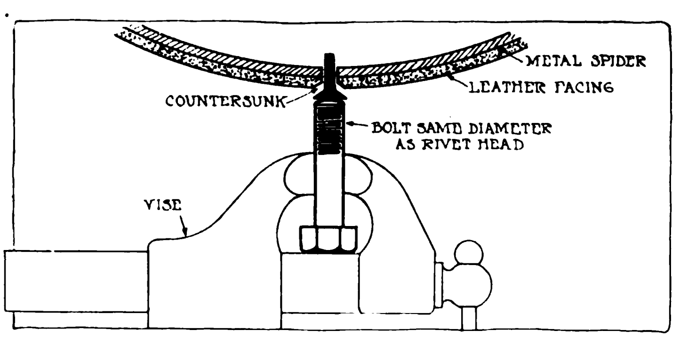

Fig. 6—Use of a bolt to countersink the rivets into the holes in the leather

The Engineering Digest

Power Testing Apparatus by Which Incidental Resistances are Obviated and First Readings are Final

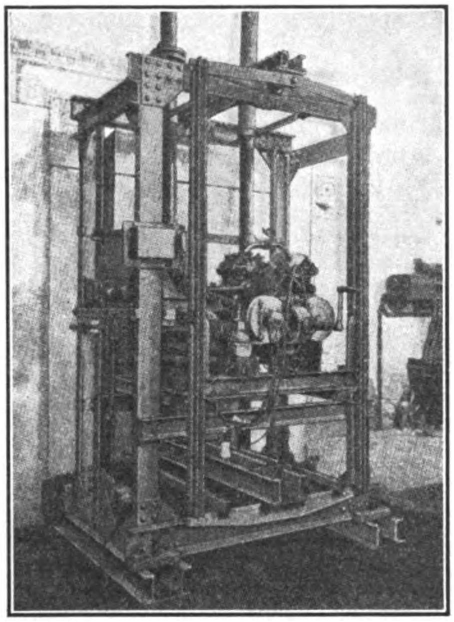

Fig. 1—The Breslau pendulum testing stand with motor mounted in it

When automobile and aviation motors are to be tested for brake horsepower at the Royal Technical College at Breslau, Germany, they are now mounted in a pendulum frame which has been designed and built at the laboratory of the institution, and the reaction of the frame upon a balance beam device serves for measuring the forces applied, in a manner which has been found accurate and convenient.

The very brief description of this apparatus furnished by Professor Baer of Breslau is amplified by the accompanying illustrations, Figs. 1 to 5, on which the principal dimensions are marked in millimeters. Fig. 1 gives a general view of the arrangement, with an air-cooled motor mounted for testing.

The deformable, motor-supporting cage suspended in the channel-iron stand consists in the essential features of two vertical frames, one at each side of the motor—which hangs upon a special cradle or barrow between them—both resting upon a rocker frame at the bottom, which acts as two pairs of parallel crankarms to receive motion from one or the other of the vertical frames, and the movement is guided by a rocker frame at the top. Fig. 2 shows details of the vertical frames and Fig. 3 those of the rigid lower rocker frame which supports them and is actuated by them when the motor is working.

The lower supports, which take up the motor power and the weight, are provided with knife-edge bearings, designed as shown in the left portion of Fig. 4, while the upper ones which only guide the action and transmit no power have ball bearings. The rocking motion of the supporting-frame also takes place upon a knife-edge bearing under the middle of it. The cradle which carries the motor (in some cases placed upon an intermediate rubber mat to absorb vibration) is hung by means of hook-shaped hangers with knife edges in pans secured in the struts of the vertical frames, on the plan shown to the right in Fig. 4.

The motor is so placed in this hanging cradle that the crankshaft extends horizontally in the middle plane between the two pairs of knife-edge bearings of the hangers and at the same level; this having the effect that the motorshaft remains quiet at small movements of the cage.

By means of special compensatory weights the center of gravity of the unit comprising the motor and its cradle can be displaced along the axis of the shaft in order to obviate the influence of unequal weight distribution, but, as an elaborate compensation by this means is in many instances unnecessary, other slidable compensation weights are provided in sufficient variety on both of the balance beams at the sides of the cage, and these weights can be more readily used to offset approximately any unequal weight distribution which might cause twisting and resistance in the ball bearings at the top of the cage.

The load for the motor is produced by a fan dynamometer brake, and this is operated inside of a strong and broad wooden casing (to help in equalizing the atmospheric conditions for any series of tests) and is calculated to give a 12-horsepower resistance at 1,500 revolutions per minute.

The torque developed by the motor reacts against the

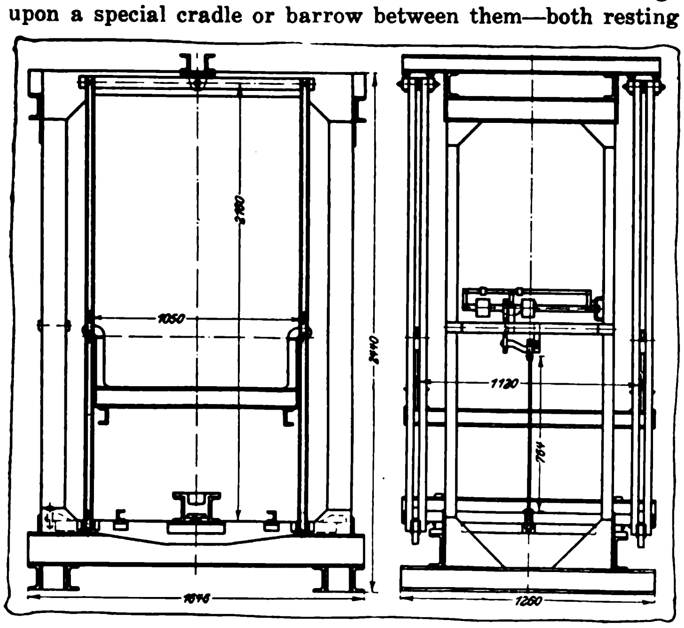

Fig. 2—Front and side views of deformable cage

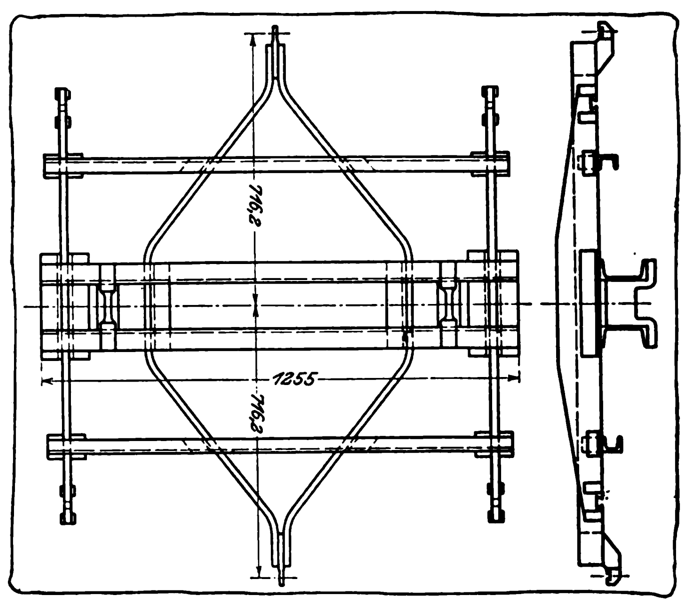

Fig. 3—Rocker frame supporting the cage

cradle and from the latter is transmitted to the vertical struts and from these to the lower rocking frame. By means of tension rods—see Fig. 2—which are disposed at a distance of 716.2 millimeters at both sides from the central vertical plane of the apparatus, the torque is carried to one or the other (according to the sense in which the motor turns) of the two balance beams. Their construction is indicated in Fig. 5. Here the force is measured which balances, at a distance of 716.2 millimeters from the motorshaft axis, against the torque developed.

The unavoidable small oscillations and vibrations are absorbed in a little hydraulic dashpot, which is operated with

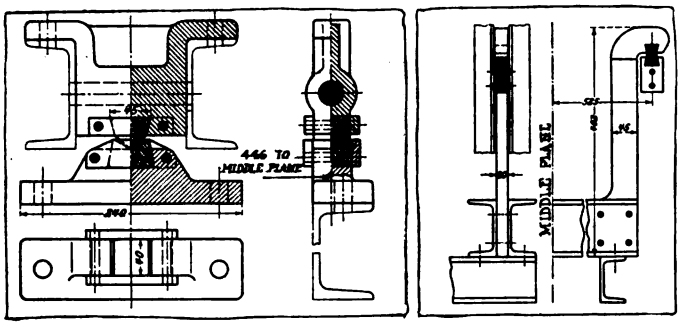

Fig. 4—Knife-edge bearings for cage and motor cradle

water but patterned after those used with oil for the regulation of centrifugal governors.

The feed pipes for fuel and lubricant are made of very flexible copper tube and the cooling-water is taken to and from the separately mounted radiator by flexible rubber hose. [Near the equilibrium, where the final measurements are taken, the resistance represented by these flexions are of course almost nil, if the original arrangement of the tubes is

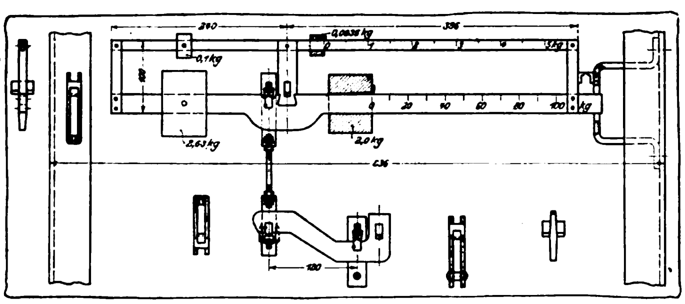

Fig. 5—Balance beam operated by rod from arms of rocker frame

made for this position.] The fuel consumption is measured by using a tank placed on a balancing scale and ascertaining the weight of the fuel used for a given time with a constant motor load, in the manner now widely adopted. A special device for measuring all the air consumed is also on hand at the institution. From *Zeitschrift des Vereines Deutscher Ingenieure*, September 12.

Special War Service Provided for German Motor Engineers

WITH a view to providing rapid solutions of engineering problems arising during the course of the German war for world domination, the Verein Deutscher Ingenieure (Society of German Engineers) has arranged a Central Shop for Engineering Work in the society's building in Berlin, where all members not subject to field service may work on assignments. Each of them must first send detailed information of the working field in which he has special experience.

A volunteer motor boat corps is also organized for river service. Former naval officers who are incapacitated for other work and graduated engineers are to command the boats.

Control of Materials and Dimensions in German Manufacture of Steel Balls and Ball Bearings

(Continued from last week)

THE apparatus arranged in the room for the testing of finished bearings serves a number of different purposes: (1) To try out the current manufacture; from time to time bearings are taken at random from the supply on hand and are tried under severe conditions for their reliability in all their functions; (2) to enlarge the scientific foundation for the construction of ball bearings; (3) to try out the manner of mounting and operating the bearings in mechanisms of widely different purposes, with imitation of such features in practical operating conditions as dust, humidity, high temperatures; (4) to try new designs in the field of parallel, roller and ball bearings; (5) to try ball bearing materials, and (6) for making tests to order for the authorities or industrial institutions.

The scope of the department is perhaps best made clear by mentioning some of the test results.

A No. 306 bearing with a brass ball cage lined with white metal was lubricated with a few drops of oil and then run for five months without further lubrication at 1,500 revolutions per minute and under the maximum load for this speed, 220 kilograms, running 12.5 hours daily or a total of 1,579 hours. At the end of this time the bearing had to be dismounted, as the inner race began to suffer from lack of lubricant, but the cage, the balls and the outer race remained uninjured.

Annular Bearings for Bicycles

The use of three-point ball bearings with adjustable cones has survived in bicycles until the present day. It was attempted, to be sure, after the first successful introduction of annular bearings in automobiles to apply this simpler type to bicycles as well, but errors in design and mounting combined with insufficient protection against dust and humidity led to unsatisfactory results. To remedy this situation, however, the D. W. F. firm three years ago brought out complete bicycle hubs in which annular bearings, supplemented by end-thrust bearings, are effectively protected against dust, water and loss of lubricant as well as against the pinching and warping of the bearing rings to which the light cycle construction has been especially liable. To test the new construction in comparison with the so-called cone bearings (meaning the adjustable ball bearings) the following arrangements were made: The same bicycle was successively fitted with the cone bearings and with the new annular bearings and in each condition was tried with and without load. The provisions were to some extent typical of the variety of facilities required for measuring the fitness of any given style of bearings for any one of its uses.

The bicycle was placed with its rear wheel on two wooden sheaves arranged tandem, and these were turned with a slightly concave circumference; the front wheel was supported on a broad and flat-rimmed wooden sheave. The place of the crankarms was taken by wood pulleys driven by belting from a jackshaft underneath, and the front wheel was likewise belt-driven from one of the sheaves driving the rear wheel, and the whole complex of pulleys was actuated, also by belt, from a direct-current electric motor of 1.9 horsepower. With all shafts mounted in ball bearings and the use of very thin and non-slipping belts the power consumption in the stand was small. The current consumption of the motor was measured with Weston meters and the rotary speed of the crankshaft with a tachometer made by Morell at Leipsic. The motor was run for one hour or until the current consumption became constant for a given load, and readings for the test arrangement were then taken for ten minutes with intervals of a half minute. From the results was to be deducted the resistance of the apparatus, varying with the load. To determine this resistance the bicycle was taken off and in its place a shaft with a brake disk was mounted in its place exactly where the crankshaft was before; from this prony readings were taken.

[The author gives the numerical values of the readings and diagrams drawn in accordance with the same, showing that the efficiency of the two bearings, measured in proportion to the power consumption in each case, varies materially. The figures show a superiority of the annular bearing of 49.7 per cent. without load and 28.6 per cent. under load of 86 kilograms.]

Examination of Injured Bearings

Among the causes resulting in injured bearings, with regard to which complaints are sometimes made and which therefore may call for examination at the factory, the most important are (1) ovalizing due to radial pinching, (2) excessive end-thrusts, (3) dust, grit or moisture in the housing and (4) acid lubricants.

Ovalization of the outer race occurs most frequently where the housing of the bearing is made in two or more pieces, usually bolted together, and not quite circular. The balls are in such cases overloaded every time they come to one of the two diametrically opposite places where the diameter is smallest, and the result is that the ball path in the outer races shows rough abrasions in just these places. Measuring reveals no fault, as the race when dismounted springs back to its original form, but the symmetrical locations of the injury furnish sufficient indication of the cause.

Excessive end-thrusts may take effect upon the balls first, but as a rule are recognized by lesions along the whole circumference in the ball paths of both inner and outer race.

If a bearing in its mounting is not protected against the admission of dust and grit, the surface of the balls and of the paths soon get a mat instead of a polished appearance by the grinding action and after a while radial play can be observed between the two races and the balls. A frequent cause of this trouble, in the case of bearings in gearboxes, is that emery powder is used for running the gears in, with the ball bearings in their place. Rust spots due to the admission of moisture may have disappeared together with their cause, the rust being worn off entirely by the movement of the bearing, but in that case small pinholes in the races and on the balls, where the rust has been, always betray that moisture has been at work.

The effect of acid lubricants is seen in the form of many but shallow scars on both balls and races remaining as the indelible marks of the corrosion to which they have been subjected.

Saving of 7 Per Cent. of Trucks' Time

(*Continued from page* 892.)

utes for inward freight and 4 minutes for outward freight. The delays were chiefly at the rush periods. It is doubtful whether any reduction could be made here.

This time might be reduced from 8 to 3 minutes by avoiding errors in the delivery checks; by having them made out and filed at the cashier's office almost simultaneously with the placing of the freight.

To overcome this trouble one road put on sorting gangs, the result being not only a reduction in time, but also giving more space to the unloading of the cars and preventing consignments from being hidden by freight arriving subsequently.

Loading or Unloading

A reduction of 15 per cent. might be made under this heading by closer cooperation between the employees of the railroad and the truck drivers. The employment of more truckmen in the freight house to assist the drivers in handling the more bulky loads would also help.

It is questionable whether the saving in the driver's time which would result from the use of the sill or single dump delivery would justify the necessary increase in labor cost by these methods.

Loafing is not chargeable to the railroads, and depends almost wholly on the season of the year.

Moving in Freight Yard

Where the buildings are near together and the pavements in fair condition this item is negligible. However, a saving of 10 per cent. might be made by improving the pavements.

It will be noted that the total possible reduction in the saving of the teamster's time as represented in this table is 18 per cent., or between one-fifth and one-sixth of the total time spent in the yards. Since the wagons spend one-third of the day in the yards, the total saving would be between 6 and 7 per cent.

Chicago Police Fighting Muffler Cutouts

CHICAGO, ILL., Nov. 6—The Chicago police have started a vigorous campaign to eliminate the cutout nuisance, adopting new tactics by making arrests in the case of cars fitted with cutouts operated from the seat. Arrests are made even when the cutout is not being operated. The very fact that the car has a cutout which can be operated from the seat is taken as evidence and arrests follow. So far about forty motorists have been apprehended for having their cars so equipped.

Requirements Should Determine Weight of Automobile Parts

Durability and Weight Are Inseparable—Comfort a Factor—Dangers of Too Light Construction

By George W. Dunham
Consulting Engineer, Chalmers Motor Co.

PROMINENT among those points most generally discussed during the present season, regarding the different phases of automobile construction, has been weight. Weight in a motor car should be scientifically determined according to the work to be done by each part.

Always Some Trouble

The manufacturer of any article, if honest with himself, realizes that there is always a certain percentage of trouble experienced with his output, and that this percentage of trouble can be reduced only to the absolute minimum but never wholly eliminated. With our company, when three cases of a specific trouble have been reported, even though there are only three cases out of thousands of cars in service, thorough investigations are started immediately and often thousands of dollars are spent to insure that there will not be a continuation of this trouble, and that this happening was only due to chance or what is known in manufacturing as "percentage of error."

It is obvious that the more the margin of safety throughout the car is reduced, the greater the percentage of troubles is bound to be. It is also obvious that the lighter the construction, the lower the factor of safety must be.

Two other points must also be considered in determining weight. One, if a trouble should occur, will it endanger the life of the occupants, or will it merely impair the quality of the car? For instance, if a wheel breaks, some one is liable to be hurt, whereas, if the bearings in the parts supporting the springs are so small that they will wear readily and rattle soon, this is a feature that will lessen the quality of the car, but not endanger the occupants.

Second, how far shall the comfort of the passengers be considered?

The first point—safety—is by far the more important. Our steering gear could be made considerably lighter, but we consider it would be cutting too close to the danger point. Our wheels could be cut down to thinner spoke sections and lighter felloes. Here again, we would fear a percentage of broken wheels. Our axles could be lightened considerably, but we would not want to take the responsibility of the danger which might result from breakage.

In some cars the torque tube has been eliminated, which effects a considerable saving in weight but throws the entire burden of the driving mechanism into the springs. Our six is provided with a concentric torque tube. Its purpose is to hold the rear axle in the proper alignment; to relieve the springs of all work but that of supporting the car. Its advantage is apparent through the manner in which the car holds the road at various speeds, and the absence of it is shown in most cases by a car dancing and hopping when going over rough roads, cobblestones and rutted roads. The use of a torque tube practically eliminates chattering or jumping of the rear axle, when pulling in heavy sand, mud or snow.

In considering the second kind of trouble resulting from too light weight—that which reduces the efficiency and quality of a car—there are many things to be considered. Almost invariably on the excessively light cars the sheet metal used in the body, fenders, dust shield, bonnet, etc., is cut to the limit. The result is a finish which is wavy and rough; with extremely light material it is impossible to keep the paint on the bodies and the enamel on the metal work gives trouble. Another bad result of too light materials is that they soon loosen and rattle. Quite often body bracings or frame members are so lined that the panels of the body sag and wrinkle.

Comfort a Factor

The third factor in considering weight is comfort. Weight is saved on some cars by the use of small inadequate fenders, for instance, which do not properly protect the occupants of the car from flying dirt. Very frequently the size of the windshield is cut down so that a small standard size of glass can be used, saving both weight and expense, but also giving less protection to those in the car.

In the auxiliary seats many designers, probably figuring that these seats are seldom used, reduce their size until they are positively uncomfortable.

Durability Means Weight

In building a car which is best suited to the policy of building a maximum car it is not very difficult to decide which course to follow. The best car for the purpose means that it must possess some definite qualities—first, maximum safety; second, comfort, and third, stability.

Contrary to the belief of some, the extra weight which is really insurance against frequent rattles and breakages, does not increase maintenance costs. By accurate tests under normal conditions it has been proved that two cars of the same approximate size and power, one weighing considerably less than the other, consume the same amount of gasoline. In actual road work we have found that the lighter car will use as much and under some conditions slightly more fuel than the heavier car. This is true because where stability of design has been neglected it almost invariably follows that motor and carbureter efficiency have not been brought up to the highest basis. A further, and perhaps the fundamental, reason why two cars of widely varying weight burn equal amounts of gasoline is that the heavier construction means better alignment of the moving parts throughout the car and therefore less loss of power due to friction. The heavier car is almost always an easier rolling car. It clings better to the road and therefore wastes less fuel.

$15 Extra per Year

For the sake of argument, however, let us suppose that between two cars of the same approximate horsepower and size, the heavier does burn more gasoline. Experience proves that in 10,000 miles of driving, the extra cost of the gasoline burned in the heavier car would amount to only $10 to $15. In other words, in a year or year and a half of driving you would have to spend not more than $15 extra for gasoline to insure yourself a car which is always comfortable, always safe, and which gives the minimum amount of trouble.

Trade Opportunities Abroad

Consuls in Sweden, Africa, Asia and South America Report Business Openings

THAT the demand for the American automobile and motor truck in South America, Asia and South Africa is growing, is manifested by the recent reports on trade opportunities from the consuls in those respective territories. Many of these contain requests for information regarding the establishment of agencies for automobiles and accessories, while others are interested in the establishment of motor truck service. There seems to be a large demand for accessories and a fair one for trucks.

Americans have not attempted to enter the market for motor trucks in Turkey. Most of the trucks so far sold have been bought by the Army and it was reported that the Ministry of War would soon be prepared to receive bids and try cars submitted as samples with a view to purchasing 100 motor vehicles of various sorts. The trucks previously purchased have had a capacity of 2 to 5 tons and of 10 tons.

Reports from Swedish and Italian consuls have also been sent in. These requests are for the handling of American cars and accessories. Most of the consuls state, however, that the establishment of American agencies in these countries and the success of the enterprises there, would depend mostly on the keeping of the cars in stock, with repair parts.

The following trade opportunities give a brief outline as to just what is wanted. Those interested may get complete information by applying at the Bureau of Foreign and Domestic Commerce, Washington, D. C. The numbers given should be referred to when writing to the bureau.

13556. **Small Cars.**—A responsible South African business man wishes to secure agency rights for an American small car, suitable for that country. The car must be right-hand drive, good clearance, and moderate in price. An American consul writes that manufacturers should give complete description, with particulars as to prices, discounts, factory output, testimonials from users, and South African territory available. Also state if trial car could be shipped immediately, if the firm considered the proposition favorably.

13558. **Motor-car and Motor-cycle Accessories.**—A South African firm doing a good business in sporting goods, motorcycles, cycles, etc., with good up-country connections, is just opening a separate department handling accessories for motor cars, motor cycles and cycles. An American consul states that the firm will carry a very extensive stock and desires catalogues, price lists, and all available literature along these lines.

13582. **Motor Vehicles.**—An American consular officer in Sweden reports that an engineering firm in that country would like to communicate with American manufacturers of motor cars, motor trucks and motor cycles not already represented in that country, with a view to representation and selling types suitable for the market. Motor cars and trucks should be of 25 to 50 horsepower, strong and able to stand traffic on rough roads.

13587. **Motor Trucks and Other American Goods.**—An American consul reports that an American citizen, who has been residing in the East Indies for several years, was leaving for New York to represent a number of Singhalese and Tamil merchants who wish to do business with American exporters to the Far East. He is especially interested in motor trucks, but is also desirous of meeting exporters of other lines of eastern trade.

13592. **Electric Van or Truck and Runabout.**—A municipal electrical engineer in South Africa would like prices and details forwarded for one Edison battery electrical van or truck, carrying 4,000 pounds, capable of ascending an incline of 1 in 8, or 12 1-2 per cent. and a speed on level ground of 10 to 12 miles per hour. Prices are desired for chassis only and for completed car landed at a certain South African port. Specifications should indicate full mileage for each battery charge, assuming one-half distance with full load and the other half light. Quotations are also desired for an electric runabout capable of carrying four persons. Edison batteries are desired. Prices quoted should be for complete car with accessories. The same standard voltage for both vehicles would be considered an advantage.

13599. **Motor Vehicles.**—An American consul in Sweden has transmitted the name of a firm in his district which desires to be placed in touch with American manufacturers of motor vehicles.

13610. **Motor Vehicles.**—A report from an American consul in Asia states that inquiries have been received at the consulate relative to the possibility of purchasing an American automobile with which to inaugurate a passenger service between two points. It is intended to purchase more cars if the service can be operated successfully. American manufacturers interested are requested to send advertising literature to the persons named in the report.

13631. **Motor Trucks.**—An American consul telegraphs from one of the European countries stating that an American located in his district desires prices immediately from reliable manufacturers in the United States for all available 1 to 3 ton motor trucks, delivered. Prices should be cabled to the address given in the report.

13808.—**Automobiles and Accessories.**—A large firm in a European country has reported to an American consular officer that it wishes to buy small automobiles to sell from $500 to $1,000 each; also tires and accessories are desired. The firm pays cash f.o.b. vessel. Correspondence may be in English.

13925. **Automobiles and Accessories.**—A firm in southern Europe has advised an American consul that it desires to represent American makers of and dealers in low-priced automobiles and accessories. It is explained that the firm believes there is an excellent demand provided the cars can be kept in stock with repair parts. Cars selling for less than $1,000 are desired. Catalogues and correspondence should be in Spanish or French.

14005. **Magnetos and Spark Plugs.**—A firm of aeroplane builders in the Near East, which states it is in a position to offer the best of references, has informed an American consular officer that it buys magnetos and spark plugs. Correspondence should be in English.

14118. **Automobiles.**—An American consular officer in Latin America transmits the name and address of a firm in his district which is desirous of getting into touch with American manufacturers and exporters with a view of representing them on a commission basis. The firm is interested in the following lines: Automobiles and parts and lubricating oils. The firm desires catalogues, price lists, etc., covering the above lines. Correspondence should be in Spanish. References are given.

14139. **Automobiles.**—The Bureau of Foreign and Domestic Commerce is in receipt of a request from a foreign consular officer resident in the United States for the names and addresses of American manufacturers of low-priced automobiles.

14145. **Automobile Accessories and Tools.**—A firm in Italy has advised an American consular officer that it is anxious to receive offers from American manufacturers and exporters of automobile accessories and tools. The consular officer has forwarded Italian catalogues covering the desired articles. These catalogues may be inspected at the Bureau of Foreign and Domestic Commerce and its branch offices.

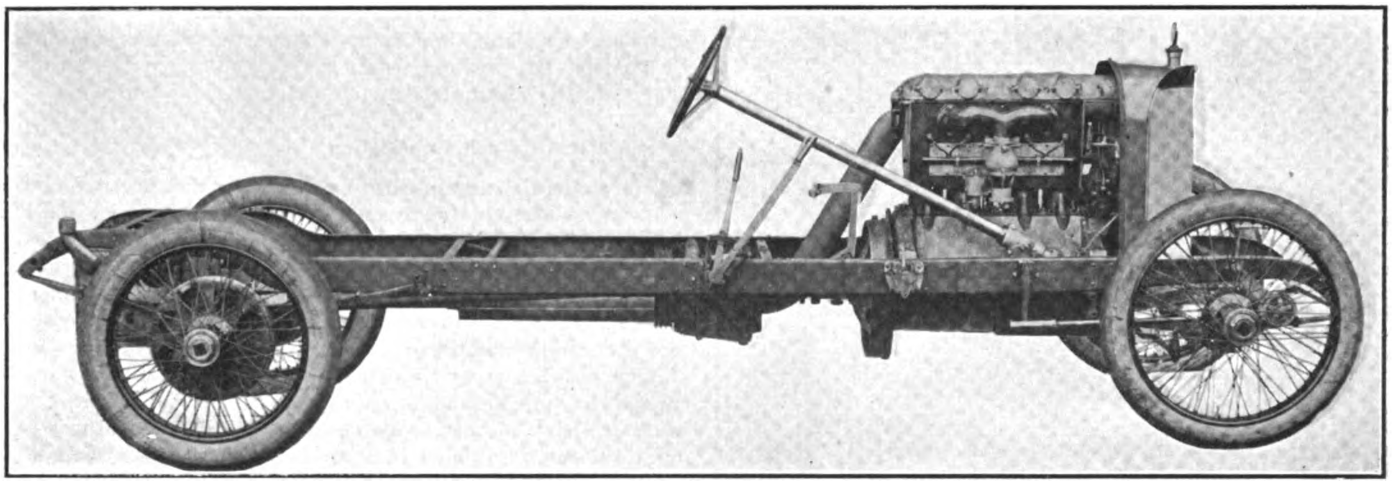
14150. **Automobiles.**—An American consular officer in South America advises that a merchant in his district, who now has the agency for a European automobile wishes to represent, directly, in his market a cheap American automobile ranging in price from $400 to $600. Correspondence should be in Spanish. Agency conditions and prices f.o.b. New York should be given.

United Electric Reduces Storage Battery Rate

NEW YORK CITY, Nov. 6—The United Electric Light & Power Co., this city, announces a reduction in the minimum monthly charge on the storage battery rate, from $25 to $10 per month beginning with November.

The company is also distributing a list of garages and charging stations in the Metropolitan District to the owners of electric vehicles operating in Greater New York and such other owners as request same.

The list is on a heavy cardboard and is designed to be tacked firmly in the vehicle in order that the operator may determine at a glance the nearest station for boosting his vehicle when such is required.



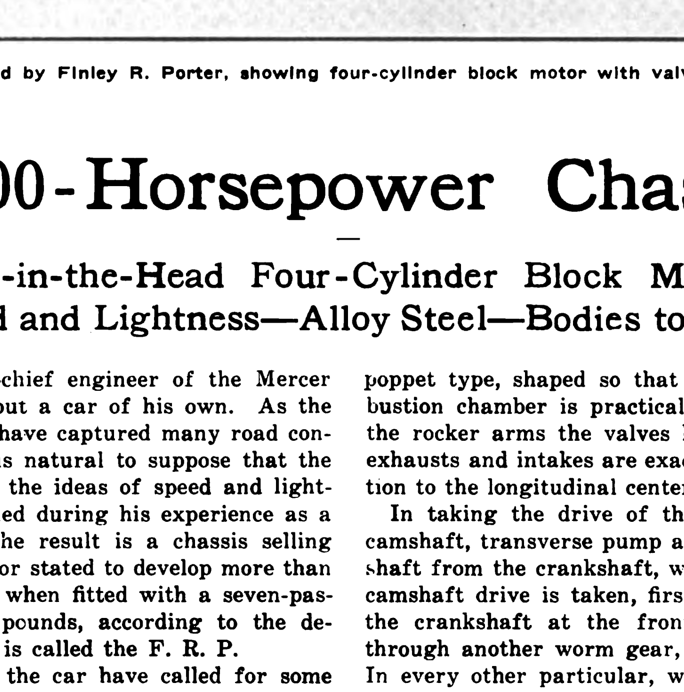
100-horsepower chassis designed by Finley R. Porter, showing four-cylinder block motor with valves in the head, V-radiator, etc.

F. R. P. 100-Horsepower Chassis, $5,000

Valve-in-the-Head Four-Cylinder Block Motor—Speed and Lightness—Alloy Steel—Bodies to Order

FINLEY R. PORTER, ex-chief engineer of the Mercer company, has brought out a car of his own. As the designer of cars which have captured many road contests in the 300-inch class, it is natural to suppose that the new car would incorporate all the ideas of speed and lightness, that Mr. Porter has gained during his experience as a creator of racing vehicles. The result is a chassis selling for $5,000, incorporating a motor stated to develop more than 100 horsepower and weighing, when fitted with a seven-passenger body, less than 3,500 pounds, according to the designer's figures. The new car is called the F. R. P.

The exceptional qualities of the car have called for some radical work in the use of materials and dimensions. As a unit, the chassis is a study in the use of alloy steel. Practically the entire steel work is of chrome vanadium, so heat treated as to meet the required specifications as to strength and rigidity. In every possible part a magnesium-aluminum alloy of great strength has been used. Tubular connecting-rods, crankshaft and driveshafts, steel pistons, steel-iron cylinders, etc., also play their part in the development of the 580-pound power plant.



Exhaust side of four-cylinder 4.6 by 6.75-inch block motor used in F.R.P. chassis, showing detachable cylinder head, mounting of Bosch electrical system and circulating pump

Valve-in-the-Head Motor

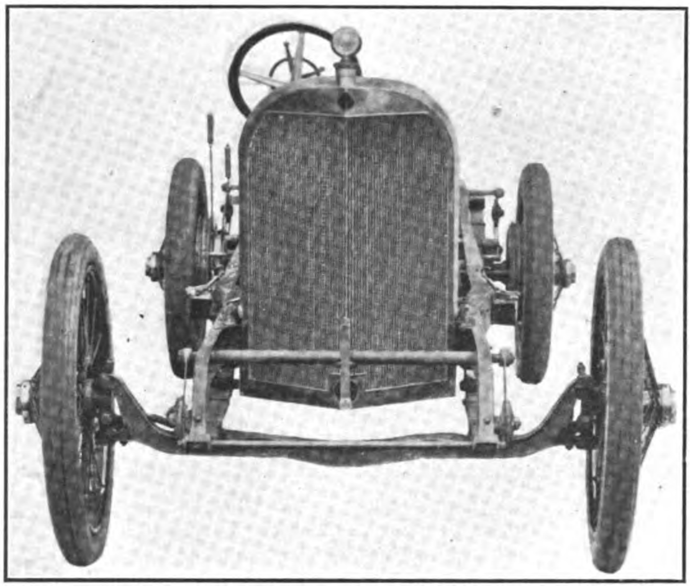
The motor is a four-cylinder 4.6 by 6.75-inch design, with valve-in-the-head cylinders cast in a block, the A. L. A. M. rating being 33.9 horsepower. The valves are operated by rocker arms from an overhead camshaft. They are of the 45-degree poppet type, shaped so that when they are closed the combustion chamber is practically a hemisphere. By offsetting the rocker arms the valves have been so arranged that the exhausts and intakes are exactly opposite one another in relation to the longitudinal center line of the cylinders.

In taking the drive of the auxiliary shafts, namely, the camshaft, transverse pump and magneto shaft and generator shaft from the crankshaft, worm gears have been used. The camshaft drive is taken, first through a vertical shaft from the crankshaft at the front end of the motor and then, through another worm gear, it is imparted to the camshaft. In every other particular, with the exception of double, 80-pound valve springs, the design does not depart from ordinary valve-in-the-head practice to any radical degree.

14 Miles to the Gallon

From tests so far conducted by the makers, the fuel consumption is estimated to be in the neighborhood of 14 miles to the gallon. The high efficiency of a motor of this size has been gained to a large degree by the high compression which is 112 pounds gauge. The test chassis upon which the experimental work has thus far been carried out has a gear reduction of 3 to 1 on direct. It has shown a speed of 88 miles an hour on the Long Island Motor Parkway.

The tubular connecting-rods are 16 inches long and are of chrome-vanadium steel with .40 carbon. The pistons are nickel steel, .20 carbon



Front view of chassis used in F. R. P. car, showing special V radiator. Note the light, strong design, wire wheels with racing type hubs and Motometer on radiator cap

and are fitted with two rings. They are 5 inches long and have a clearance of .015 inch. They are fitted with two rings above the wristpin. The wristpin bearing is 1.25 inches in diameter and 3 inches long.

The crankshaft is a chrome-vanadium forging with .40 carbon and has a diameter throughout its entire length of 2.5 inches. The center has a hollow core of 1.625 inches diameter. The shaft is carried on three bearings, each having the diameter 2.5 inches, the front bearing being 3 inches in length, the center 3.25 and the rear 5. The bearings are lined with Kelly bronze.

Valve Diameter Is 2.5 Inches

By eliminating the cage construction it has been possible to carry the valve diameter up to 2.5 inches. This plan has been rendered feasible on account of the close proximity of the water jacketing space which is within .25 inch of the valve seat. The valve stems and heads are of tungsten steel and they have a lift of .375 inch. The cams which act directly upon the rocker arms are in a unit with the hollow chrome vanadium camshaft. This shaft has a 1.375-inch exterior diameter and a hollow core 1 inch in diameter. By carburizing the outside of the cams before heat treating the shaft, the exceptional carbon content of 1.0 per cent. has been reached on the surface of the cams, giving a glass-hard bearing face. The rocker arms are not returned to their initial positions solely by the valve springs, but have in addition to these a coil spring of 40-pound-pull, hooked between each pair of exhaust and intake rockers across each cylinder. The half-time ratio is imparted to the camshaft by gearing the vertical worm shaft 1.5 to 1 to the crankshaft and the camshaft 3 to 1 to the vertical wormshaft.

Pressure and Splash Lubrication

Lubrication is accomplished by a combination pressure and splash system. On the bottom of the vertical worm shaft there is a rotary piston pump with four independent leads. One of these leads goes to each of the three main bearings and the fourth is carried to the rear camshaft compartment and connects with a pressure gauge on the dash which registers the pressure on the oil pump. This pump produces about 30 pounds pressure at 1,500 revolutions per minute and has a capacity up to 600 pounds which is sufficient to clear the line in all ordinary cases of clogging. The valve mechanism is so arranged that it is held in a series of cup-shaped compartments at each cylinder. The oil, after filling the rearmost compartment, drains forward and fills in turn each of the others. These compartments are short and deep, providing against spilling the oil on steep grades. By this arrangement the entire valve mechanism operates in a bath of oil.

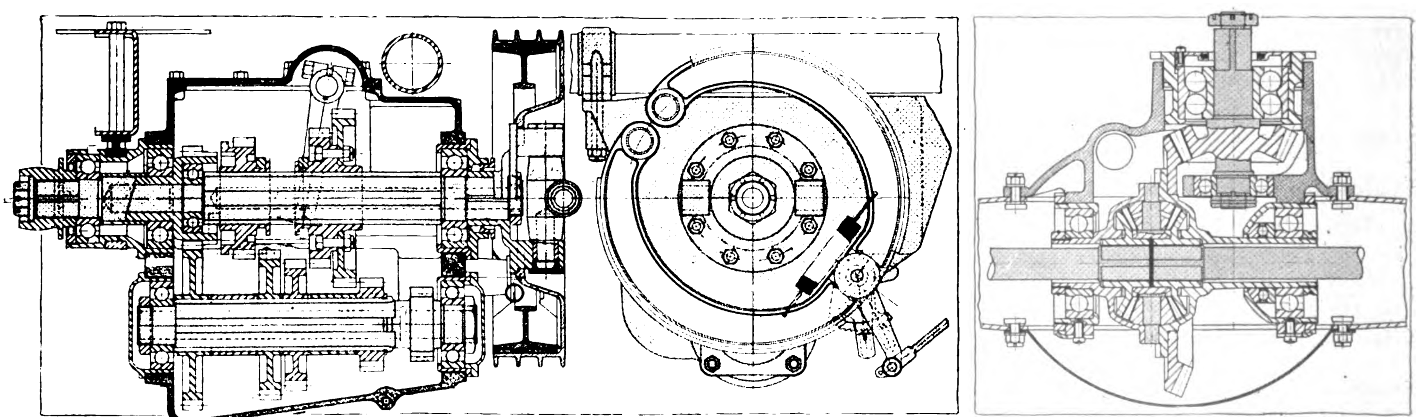
The three other leads carry the oil under pressure to the respective main bearings and after lubricating these the oil passes into a series of troughs which are held in an independent aluminum pan riveted to the interior of the lower half cf the crankcase. By means of these troughs a constant level splash arrangement is provided.

Cooling is by water circulated by means of a centrifugal pump. The water-jackets are large and in addition there is an efficient V-shaped radiator which has been made specially by the Mayo company for this car. It has a radiating area of approximately 20 by 26 inches and the honeycomb tubes are 3 inches long. The support of the radiator has been carefully worked out. It is a three-point scheme. The two bottom points are composed of vanadium steel ball trunnions in manganese bronze brackets and the third point is formed by a tie rod across the top.

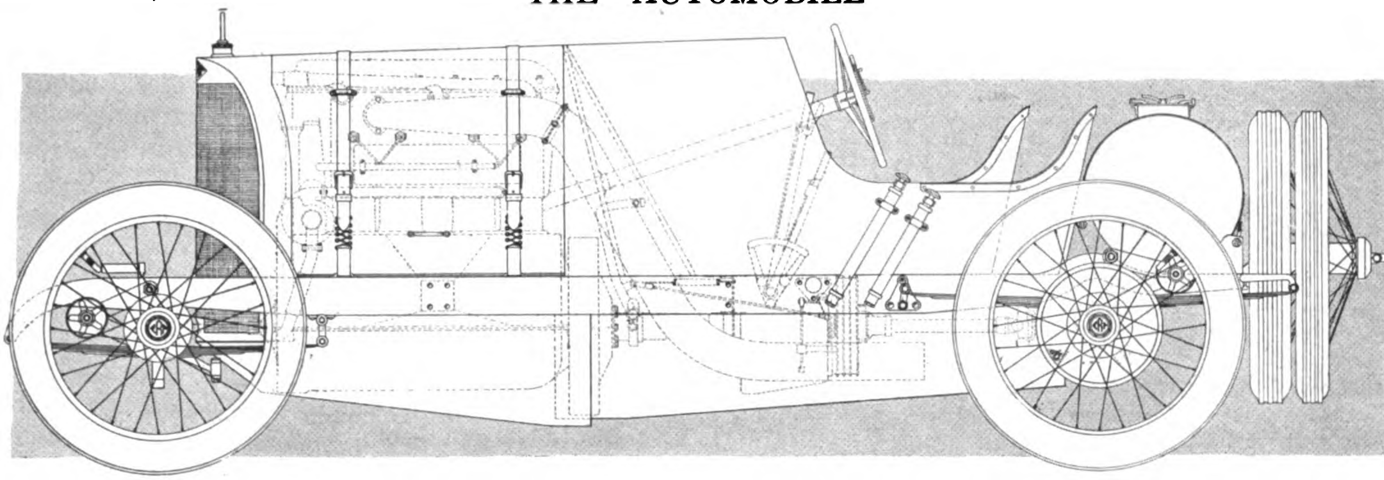
Bosch Electric Plant

A complete Bosch electric plant is supplied with the chassis. This takes care of ignition, lighting and starting. For ignition a two-point scheme, which has as its current source a high-tension magneto, is provided. For starting there is the Bosch 12-volt motor which is geared 7 to 1 to the crankshaft and which is capable of spinning the engine more than 150 revolutions per minute under ordinary circumstances. The generator is also a Bosch 12-volt unit driven at crankshaft speed and capable of carrying the entire lamp load at 12 miles per hour. The entire electric system is worked on the single wire plan and the battery is a Willard 50-ampere hour 12-volt.

The clutch is a cone housed within the flywheel. The fly-



Left—View through three-speed gearbox used in F. R. P. car. Middle—Transmission brake. Right—Section through rear axle



Side view of racing type body mounted on F. R. P. chassis, showing the mounting of the power plant, control features, etc., by means of the dotted lines. Note spare wheels carried at rear

wheel is 21 inches in diameter and is a steel forging providing a clutch surface 19 inches in diameter and 2.5 inches face. Between the clutch and the gearbox there is a compensating joint which can take care of misalignment in any direction. The gearbox provides four forward speeds with direct on fourth. It is carried on annular ball bearings and is provided with a transmission brake which acts as service equipment. This brake shaft, together with the clutch thrust and sliding members, is oiled by the lubricant which passes through the hollow crankshaft by means of a specially drilled lead. The entire gearbox assembly weighs but 80 pounds.

Drive Is Through Rear End of Springs

There are two universal joints in the drive of air-hardened steel. These, together with practically every bolt and nut in the car, are manufactured in the plant of the makers of this car. The drive is delivered to a five-pitch, four pinion differential. The gears are chrome vanadium with twenty-one teeth in the pinion and sixty-one teeth in the crown wheel, giving practically a 3 to 1 reduction. The car is driven through the rear ends of the rear springs. This being done to have the starting moment exerted in settling the chassis downward instead of raising it. All the special bolts and cross shafts in the drive are fitted with graphited bronze bushings which are self lubricating.

The emergency brakes are on the rear wheels and have 16 2.5-inch drums into which they expand. The steering gear is a worm and full gear type also worked out in the designer's plant. It has a magnalium housing with a ball thrust. The column is a 2-inch stationary post with three levers, the third being for carbureter adjustment. The wheelbase is optional and the chassis is sold with full electric equipment.

Mitchell in Good Shape After 7500 Miles

PITTSBURGH, PA., Nov. 9—The seals on the Mitchell sealed bonnet reliability car, which finished its 30-day run of 7,500 miles, with the seals intact, were broken on November 4 in the showrooms of the Williams-Hasley Motor Car Co., by F. E. Edwards, technical expert of the Contest Board of the American Automobile Assn.

After his examination of the car Mr. Edwards sent in his report to Chairman Kennerdel of the Contest Board, who approved of it and declared the car a stock model.

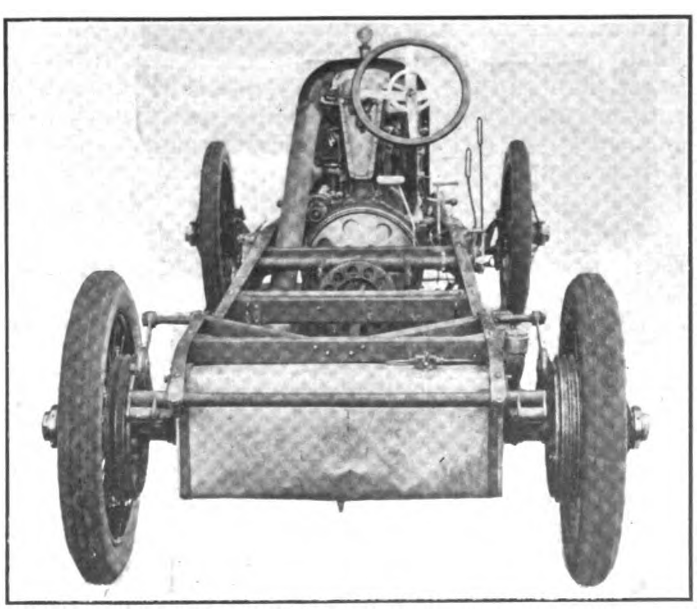
When the seals were broken the engine was gone over and minutely examined. The valves did not need regrinding, having only a very small deposit of carbon; the bearings were snug; the clutch showed no signs of wear and the transmission and rear axle were in good condition. The brakes were shy of two rivets.

When the seals were broken all evidence of the muddy roads which it had traveled was apparent, the drip pan alone containing over 85 pounds of mud and sand.

The car was equipped with a Stewart vacuum gasoline tank, which is now regular equipment on the Mitchell. An average of 15 1-2 miles to the gallon was made for the trip. No record was kept of oil consumption, which was light.

Packard Is Now an All-American Car

DETROIT, MICH., Nov. 5—Vice-president and general manager Alvan Macauley of the Packard Motor Car Co., has announced that all the materials necessary in the construction of Packard cars are now available in America and that the company does not have to apply to any foreign country for any required material. Had the war occurred 10 years ago the company would have had to close down as at that time it was dependent almost exclusively on foreign manufacturers for the following articles needed in the construction of its cars: French cylinder castings, piston and piston ring castings, cone steel for ball bearing races, ball bearings, Fulmen storage batteries, spark coils, magnetos, spark plugs and spark porcelains, high-tension ignition cables, timers, commutators, motor valve forgings, silico manganese gear steel, door locks, door handles, all cloths, laces and silks for trimmings, goat skins for inclosed body upholstery, horns and bulbs.



View of F.R.P. chassis, looking forward, showing large fuel tank in rear, brake drums ridged for cooling, large exhaust manifold, which is a two-part stamping, etc.

Factory Destruction

AN unfortunate aspect of the present war in France is the destruction of some of the automobile factories in northern France. On other pages of this issue are shown views of one leading French factory that was bombarded and finally burned. Unquestionably this fate awaits other plants in the war zone. To date nothing definite has been given out regarding factories located in several cities that have suffered prolonged sieges.

It is unpleasant to contemplate profiting from the unfortunate experiences of rivals, but this factory destruction points more and more certainly to the situation that will rule when hostilities cease. It is weekly becoming more apparent that many of the continental factories will be in a condition of utter disorganization when the war ends, and that it will take a year, perhaps longer, for them to get on a production basis. Automobiles will be needed and the American market will be looked to in supplying this demand.

At present the war departments are asking for small touring cars. The demand is for a small four-cylinder car. Europe has never been a strong advocate of the six, preferring the small high-efficiency four. The American concerns that hope to profit by the fate of war and its destruction should aim to be ready to supply nearest to what is demanded. The good merchant always has on the counter those goods that are in most demand. This is a good leaf from the book on exporting to keep in mind when developing a new export business after the close of the war.

A Truck Show?

THE National Automobile Chamber of Commerce, Inc., at its regular monthly meeting last week acknowledged in a more or less direct way that there is at least some necessity for a motor truck exhibition, a position in strong contrast with the stand taken by this organization nearly 2 years ago, when it voted to discontinue truck shows.

It is not proposed to have truck exhibits at the New York or Chicago show, but rather that space be set apart for the use of the thirty-three makers of trucks who are members of the association.

This shows a tendency in the right direction, a movement which will serve to bring motor trucks to the attention of the industry during the show circuit. The motor truck is more in the public eye today than it has been since its inception. It is revolutionizing the present war, and, in fact, although in general use at present, gives promise of being utilized in every department of the war.

It is regrettable that more members of the American motor truck industry are not represented in the membership of this national governing body. There are many truck makers who are not members of any organization, but who should be, and who are consequently suffering that loss, which always comes from not being members of such industrial organizations that are for the benefit of the industry.

Organization is one of the best indications of progress. The organization can accomplish what is impossible with the individual. Every movement that aims to broaden the scope of organization is welcomed.

THE AMERICAN MOTOR TRUCK INDUSTRY IS LARGE ENOUGH TO WARRANT SOME COLLECTIVE DEMONSTRATION ONCE A YEAR BEFORE THE NATION. THIS DEMONSTRATION MIGHT BE IN THE FORM OF SOME GREAT CONVENTION; IT MIGHT TAKE OF THE NATURE OF A NATIONAL DEMONSTRATION; OR IT MIGHT ASSUME THE PROPORTIONS OF SOME SUITABLE FORM OF SHOW, OR COMBINED SHOW AND DEMONSTRATION. LET IT BE SOMETHING.

Unfortunately at the present time the American motor truck industry is not a unit as it should be. There are some of the older concerns that apparently do not welcome all the newer companies into the older organizations. At present some of these new concerns are not perhaps following as orthodox methods of merchandising as a few of the older companies. This is one of the prime reasons why closer organization is desirable. The truck industry deserves collection protection, and it is natural to expect that the older members of the industry will bear their share of this burden.

1,600 Good-Roads Delegates in Atlanta

Fourth Annual Convention of American Highway Assn. Sets New Record—Good Roads Making Fast Progress—18,000 Miles of Hard Roads Built in 12 Months

By J. C. Burton
(Staff Correspondent)

ATLANTA, GA., Nov. 9—Fifty years ago the forces of North and South met in Atlanta to decide a question over which there was a decided difference of opinion. Today, the forces of North and South again met in Atlanta to discuss a question of almost equal economic and social importance but one in which each side shares the other's sentiments. Fifty years ago, the forces of North and South assembled under different flags. Today they rallied around a common standard, the gonfalon of highway improvement.

Atlanta Under Siege

Since early yesterday, the historic city has been in a state of siege. In the past 36 hours, more than 1,600 delegates, recruited from all sections of the country, have swept down upon Sherman's base of supplies in 1864 to attend the fourth annual American Road Congress, which opened this morning and will continue throughout the week and which is being held under the auspices of the American Highway Association, the American Automobile Association and the Association of County Commissioners of Georgia.

Never before in the history of national conventions for the purpose of advocating the building of good roads has there been as much enthusiasm shown as is being displayed here. Never before has the American Road Congress attracted so great a crowd of delegates as has the conclave of this week. The cities along the Atlantic seaboard alone sent sixteen Pullmans full of delegates. Even far off California and Washington are represented. Moreover, it is a most representative gathering. All except five or six states of the forty-eight in the sisterhood have sent their highway engineer or commissioner to attend the sessions.

18,000 Miles in 12 Months

In his opening address, Logan Waller Page, director of the United States office of public roads and president of the American Highway Association, reviewed the good road work of the past year to prove that the campaign is nation-wide in importance and one in which every state, county and township now is vitally interested. During the past 12 months 18,000 miles of hard-surfaced roads had been built in this country at a cost of more than $200,000,000.

Speaking of the use of convicts for road work, President Page said:

"An exceedingly important factor that has come into prominence in solving our road problems during the past 10 years is that of convict labor. Many of the states are using their convicts in the building of roads and the preparation of road materials and I congratulate Georgia on her lead of all the states in this respect. Georgia, I understand, now has a great road-making army of more than 5,000 convicts which is rapidly transforming the road system of the state. We have estimated that the total convict labor days on road work throughout the United States will exceed 3,000,000. As indicating the trend of this movement, I might say that during the year the states of Ohio, New York, Wisconsin and West Virginian have authorized the use of convicts in this way, thus indicating that this policy has no geographical bounds to its field of usefulness."

Other speakers were Governor John M. Slaton, of Georgia, Mayor James A. Woodward, of Atlanta, President Austin B. Fletcher, of the American Road Congress, Robert P. Hooper, former president of the American Automobile Association and Lewis B. Speare, president of the Massachusetts A. A.

Cotton Belt Route Proposed

ATLANTA, GA., Nov. 10—*Special Telegram*—Coincident with the Fourth American Road Congress which is being held at Atlanta this week, plans for a new motoring highway to connect Chicago and Jacksonville and to be known as the Cotton Belt route, were born here today. William S. Gilbreath, of Indianapolis, Secretary of the Hoosier Motor Club is sponsor for the project which originated with Carl Fisher, builder of the Indianapolis Motor Speedway and father of the Lincoln Highway.

According to present plans the proposed North-and-South link in the country's chain of motor roads will pass through Indianapolis, Louisville, Nashville, Chattanooga, Atlanta, and Macon giving the motorists an opportunity to visit en route such places of historic and scenic appeal as the Lincoln Farm, the Mammoth Cave, the Blue Ridge mountains of Kentucky and Tennessee and the Civil War battlefields in the vicinity of Chattanooga and Atlanta.

U. S. Army To Test Motor Tractor

WASHINGTON, D. C., Nov. 7—The conclusion has been reached by the war department, at the instance of the army board of ordnance and fortifications, that it would be advisable to have a comparative test of types of motor tractors, with a view of ascertaining or developing a vehicle of such design and manufacture as will make it useful to the army in the transportation of ammunition, supplies and equipment.

More than a year ago the board made an allotment for the purpose of acquiring a French motor tractor, which one of the American military observers found was used extensively and effectively in the French military service. Efforts were made to obtain this vehicle but after much correspondence and several increases in the allotment it was ascertained that the French makers of the vehicle were not willing to sell outright the tractor and the proposal to loan the vehicle for the purposes of experiment came to nothing, the war in Europe intervening to terminate the negotiations.

The suspicion has been entertained that the foreigners were, for some reason, not particularly desirous of sending over any of their vehicles. This circumstance has served to postpone the test which was contemplated and which, it was proposed by the board of ordnance and fortifications, should be conducted by representatives of various branches of the service.

Now it is recommended that the test be conducted of vehicles of American design and manufacture. It was contemplated that the test should be under the auspices of the board of ordnance and fortifications, but the secretary of war has decided that it shall come under the general staff. That body is now gathering information for the purpose of having extensive experiments. In the meantime contracts continue to be awarded by the quartermaster general for trucks.

Recently bids were opened for furnishing two four-wheel-drive motor trucks for the army. The specifications were drawn as a result of tests by the quartermaster corps of various trucks designed for army purposes. The following bids were received: Duplex Motor Co., Charlotte, Mich., $2,200 each; Thomas B. Jeffery Co., Kenosha, Wis., $2,500 each; Driggs-Seabury Ordnance Co., Sharon, Pa., $2,640 each: Four Wheel Drive Auto Co., Clintonville, Wis., $2,380. Contracts will be awarded in the near future.

Stevens-Duryea Sales Total $3,503,500.94

End of Fiscal Year Shows 14,000 Cars Built Since Inception of Company

ATWATER KENT AND HUPMOBILE BUSINESS GROWS

CHICOPEE FALLS, MASS., Nov. 9—The Stevens-Duryea Co. has issued its statement for the fiscal year ending October 31, 1914. In a letter accompanying the statement the company calls attention to its liberal reserves for depreciation, and to the fact that nothing is carried to the credit of the company to cover patents, drawings, patterns or good will. The total sales for the past business year have been $3,503,500.94. Since beginning business the company has sold 14,000 automobiles. The statement is as follows:

CURRENT ASSETS:	
Cash on hand	$84,712.76
Accounts receivable	64,850.40
Notes receivable	7,235.00
Total	$156,798.16
Inventory	$1,230,769.45
FIXED ASSETS:	
Real estate, buildings and equipment	$856,185.53
Tools and machinery	861,576.10
Office furniture	17,414.60
Miscellaneous assets	63,400.00
Total	$1,798,576,23
Total assets	$3,186,143.84
LIABILITIES:	
Current Liabilities:	
Bills payable	$184,000.00
Accounts payable	25,533.77
Accrued taxes	7,993.00
Total	$217,526.77
Capital account:	
Capital stock	$300,000.00
Reserves:	
Reserves for depreciation	594,803.85
Surplus	$2,668,617.07
Total liabilities	$3,186,143.84

Atwater Kent Business Increases 800 Per Cent.

PHILADELPHIA, PA., Nov. 9—A. Atwater Kent, manager of the Atwater Kent Mfg. Works, this city, has just returned from an extended trip through the Middle West, in which the majority of the factories in the industry have been visited. He reports that indications are for a busy season next year in spite of the effects of the war. Present indications would show that more radical and rapid developments are taking place in the automobile industry at present than during the past 6 or 7 years. His company's business has increased 800 per cent. in the last year, and 1915 business will be approximately double that of the present season.

Another Dividend for Creditors of R-C-H

DETROIT, MICH., Nov. 6—At the meeting of creditors of the R-C-H Corp. held yesterday in the offices of referee in bankruptcy Lee E. Joselyn, the latter entered an order directing the Security Trust Co., trustee, to pay a dividend of 25 per cent. to all creditors whose claims accrued after October 25, 1912, the day when the extension agreement was signed. About $80,000 will now be disbursed by the trust company and it is stated that another dividend of 25 to 30 per cent. will be declared within the next 90 days. Last year a first dividend of 5 per cent. was paid.

1,382 Hupmobiles Shipped in October

DETROIT, MICH., Nov. 6—October was the biggest month of business the Hupp Motor Car Co., has ever had in the United States, according to President J. Walter Drake. The total number of cars sold and shipped was 1,382, which, considering the war and other conditions is a most remarkable and encouraging showing. During September and October the Hupmobile business has more than doubled as compared with the same months in any previous year in the history of the company. Most of the cars shipped went to the Middle West, Northwest and Pacific Coast and despite the unfavorable business conditions in the cotton belt a fair amount of business was transacted in that part of the country and reports have been received showing that conditions there are now improving.

Johns-Manville Takes Over Tirenew and Narco

NEW YORK CITY, Nov. 7—The H. W. Johns-Manville Co. has concluded arrangements with the National Rubber Co. whereby it becomes the sole distributor of Tirenew and Narco products.

These goods will hereafter be advertised as J-M Tirenew and J-M Narco products and will be subject to the same guarantee or quality that obtains on all automobile accessories, etc. sold under the J-M emblem.

J-M Narco products are mediums for making tire repairs, re-finishing automobile tops and so forth.

Marked Activity in Rubber Imports

NEW YORK CITY, Nov. 5—During the 7 days from October 16 to 22, inclusive, there reached this port 2,705,900 pounds of crude rubber, a quantity fully equal to the average of last year's imports. Steadier buying also is reported from London, and an upward movement is generally looked for.

DETROIT, MICH., Nov. 6—Within the next few days the Security Trust Co. will mail a second dividend of 12 1-2 per cent. to the creditors of the Disco Co., which made electric starting and lighting systems. This will make a total of 22 1-2 per cent. dividends paid thus far and the trust company believe that a third dividend of approximately the same amount will be paid to the creditors when the estate is finaly closed.

AKRON, O., Nov. 5—The Goodyear Tire & Rubber Co. has declared a 12 per cent. annual dividend on the common stock. This is the same as a year ago.

Final Stages in Controversy Over Horn Patents

NEW YORK CITY, Nov. 10—The latest court action in the controversy which has been carried on in the New York courts between the Lovell-McConnell Mfg. Co., maker of Klaxon horns, and the Automobile Supply Mfg. Co., Inc., maker of Newtone horns, is that Klaxon has been denied a rehearing of the case in the Circuit Court of Appeals, and has been directed to pay the costs of the suits against fourteen dealers selling Newtone horns, together with the costs of the litigation in the Circuit Court of Appeals and also the District Court in Brooklyn, where the earlier arguments were heard.

The bill of complaint of Klaxon against Newtone has been dismissed and also the bills against the fourteen dealers selling Newtone horns. The only remaining course for Lovell-McConnell is to petition for a hearing before the Supreme Court of the United States.

On October 6 the Circuit Court of Appeals denied the motion of Klaxon for a re-hearing, and confirmed the decision of Judge Coxe handed down in that Court on June 8, which held "that the broad claims in controversy of the Hutchison patents are invalid and that the claims which cover specific details, if valid, are not infringed."

On October 15 the Circuit Court of Appeals issued a mandate to the District Court for the Eastern District of New York instructing it that the decision of the District Court in favor of Klaxon handed down by Judge Chatfield January 10, 1914, was reversed with costs of $3,346.13, to be paid by Klaxon. The mandate ordered the Brooklyn Court to dismiss the bill.

On October 20 Judge Veeder issued an order in the Brooklyn Court dismissing the Klaxon bill of complaint and cancelling the bonds given by the Automobile Supply Mfg. Co., Inc., as security for costs. On October 26 an order signed by Judge Veeder fixed the costs of the Brooklyn suit at $1,436.62, and ordered that, inasmuch as this sum as well as the sum of $3,346.13 representing the costs of the action in the Circuit Court of Appeals, has been paid in full by Lovell-McConnell, the bill of complaint be dismissed. Following this, on October 31 Judge Chatfield signed an order in the Brooklyn District Court on motion of the Klaxon counsel extending the term of the court for all purposes of this suit for a period of 6 months from the date of the final decree.

Reorganize Hans Motor Equipment Co.

LACROSSE, WIS., Nov. 7—The Hans Motor Equipment Co., Lacrosse, Wis., one of the largest producers of pressure and capacity gauges, oil pumps and other motor car parts and accessories in the Middle West, is undergoing a financial reorganization under the direction of Dan W. MacMillan of Lacrosse, in favor of whom the concern has executed a trust deed. The company has a current indebtedness of about $18,000, which will be liquidated at once. It moved to Lacrosse and built a new factory with the assistance of the Lacrosse Industrial Assn. about two years ago and the reorganization is meant to place the concern on a sound footing for the future. It is stated that the company is in good condition, having materials on hand valued at $30,000 fully paid for and machinery, tools and equipment appraised at $50,000.

Greatest Year for Long Mfg. Co.

DETROIT, MICH., Nov. 9—The Long Mfg. Co., maker of radiators, has just ended its fiscal year with a 200 per cent. increase in sales over any previous year. The sales of the months of September and October reached the highest mark in the history of this company. The September production was 300 radiators per day and the specifications for spring delivery have exceeded those of any past season.

Voiturette Sold to Winternitz for $100,000

DETROIT, MICH, Nov. 10—The American Voiturette Co., Detroit, Mich., has passed into the hands of the Samuel L. Winternitz Co., Chicago, Ill. The Federal Court in Detroit today confirmed the latter company's offer of $100,000 for the real estate, accounts, notes and cash. It is stated by the Detroit representative of the Winternitz company that the building of Car-Nation cars will be continued. The receiver, the Detroit Trust Co., has requested that creditors offer proof of claims within the next 90 days.

Motor World Buys Motor Field and Merges It

NEW YORK CITY, Nov. 10—*Motor Field*, the monthly publication that has enjoyed such a large middle and far Western circulation since the inception of the automobile industry, has been purchased by the A. B. Swetland Co., New York, and will straightway be merged with *Motor World*.

It was realized that *Motor Field*, being a monthly publication, failed to adequately serve its important dealer clientele as a newspaper. Live dealers must have news of the industry quickly. All of *Motor Field's* dealer circulation will be absorbed by *Motor World*. This big addition of Western circulation to the present *Motor World* strength throughout the territory east of the Mississippi river will present a wonderful merchandising force capable of promoting material advantage both to the automobile accessory dealer and manufacturer.

Until 1 year ago *Motor Field* was published in Denver by the G. A. Wahlgreen Co., and when sold to the Van Sicklen Publishing Co. was removed to Chicago, since which time its circulation has been intensified and its scope of usefulness largely increased.

By the merger with *Motor World* there comes into existence a dominant publication that covers the dealers from ocean to ocean. The A. B. Swetland Co., publishers of *Motor World*, is a unit of the Class Journal Co., owners of THE AUTOMOBILE, *Motor Age* and *Motor Print*.

The advertising department of the Class Journal Co. will continue to represent *Motor World*, assisted by Messrs. Fred W. Van Sicklen and N. H. Van Sicklen, Jr., with Charles B. Shanks as business manager.

Allen Motor Co. Is Member of C. of C.

NEW YORK CITY, Nov. 9—At the last meeting of the Directors of the National Automobile Chamber of Commerce, the Allen Motor Co., Fostoria, O., became a member.

Handley Buys Marion —To Re-Organize Co.

Assets Bring $120,000—Announcement of Plans Soon—Sheldon Has New Axle

THREE NEW APPERSONS—CO. TO SELL NORWALK

INDIANAPOLIS, IND., Nov. 5—The assets of the Marion Motor Car Co., were sold today to James I. Handley, president of the company, for $120,000. Mr. Handley, who has been connected with the Marion company for the past few years, has arranged to surround himself with a good organization and will make a definite announcement regarding the company's policy in the near future.

The affairs of the existing Marion company have been more or less in the courts since October, 1913, when a receiver was appointed for the company. In December of that year the receiver was discharged after the creditors had agreed to an extension of their paper. In July, 1914, J. M. Edsall, the company's superintendent, offered $150,000 for the assets, which offer was refused by the Indianapolis attorney representing a number of the creditors. The sale was also objected to by the board of directors of the Marion company. Soon after this the Marion company distributed $130,000 by way of dividends. The company's matters were kept clear of the courts until recently. The policy pursued has apparently been highly approved by the creditors who are now realizing about $125,000 more than they were offered in July.

Now the Sheldon Axle and Spring Co.

WILKES-BARRE, PA., Nov. 9—In order to link together in its incorporate name both articles that go to make up the bulk of the Sheldon output, the name of the Sheldon Axle Co. has been changed to the Sheldon Axle and Spring Co.

The company has recently completed a number of large additions. The entire axle assembly department has been moved into new quarters and complete equipment of new machinery has been installed in the vacated assembly room, which is devoted exclusively to the worm gear proposition.

In this connection announcement also is made by the company of the bringing out of a new 1,500-pound worm gear driven axle which is now ready for delivery in quantities. This now gives a standard line of Sheldon worm gear drive rear axles consisting of four sizes, namely, 1,500 pound, 1, 2 and 3 ton.

The new size is identical in design with the previous sizes, using ball bearings throughout for both the radial and thrust loads in the worm itself.

Three 1915 Appersons at $1,350 to $1,585

KOKOMO, IND., Nov. 9—The Apperson Bros. Automobile Co., Kokomo, Ind., has three new models for 1915. These are model 4-40, a five-passenger car with 116-inch wheelbase and a 3½ by 5 motor listing at $1,350; model 6-45, a five-passenger car with 122-inch wheelbase and a 3½ by 5 motor listing at $1,485; and model 6-48, a seven-passenger car with 126-inch wheelbase and a 3½ by 5⅛ motor listing at $1,585.

Company Organized To Sell Norwalk Six

MARTINSBURG, W. VA., Nov. 7—A charter has been granted to C. W. Kilbourn, Max Robinson, S. P. Hopkins, of Martinsburg, G. B. Goetz, Charlestown, W. Va., and R. W. Alexander, Baltimore, Md., as incorporators of the Norwalk Distributing Corp.

The new corporation will have the sole distribution of the Norwalk underslung automobiles, and will handle both the domestic and foreign business.

It will market a light six. The general offices will be located in this city, with branch offices in New York City, covering the export department.

In October Charles G. Smith was appointed receiver of the Norwalk Motor Car Co., on petition of an officer of the company. The court granted permission to the receiver to borrow money for operating expenses and to continue the operation of the plant for 2 months, by which time it was believed the company would be reorganized.

September Exports Total 774 Cars

War Cuts Shipments 985 as Compared with 1913—Trucks Gain—Complete Statistics

WASHINGTON, D. C., Nov. 9—In addition to the figures published last week in THE AUTOMOBILE showing the exports of motor cars during September and the 9 months ending September, the following detailed figures, are herewith presented for the benefit of the industry. They are the latest figures compiled by the federal bureau of statistics and give a general idea of what conditions were up to October 1 last.

The total exports of commercial and passenger vehicles for September, 1914, dropped approximately 56 per cent. under those for the same month in 1913. For the 9 months ending September, 1914, the exports dropped only 3 per cent. below those of the same period in 1913. The exportation of parts, not including engines and tires, gained $2,371.

Eighty more trucks were exported in September, 1914, than in the same month of 1913 while the automobile exportation dropped in number 1,065. Both the loss of the passenger vehicles and the gain of the commercial vehicles amounted each to 62 per cent.

Canada was our largest buyer during September with British Oceania next. Canada purchased 260 while British Oceania purchased 219. The United Kingdom bought 136 vehicles. For the 9 months ending September, United Kingdom led with a total purchase of 5,130 vehicles valued at $4,281,026. Canada was next with 3,854 at $4,881,062.

The total value of tires exported from this country in September, 1914, amounted to $266,259 or $55,556 lower than for the same month in 1913. England was the largest buyer, the purchases amounting to $134,801.

Imports of automobiles during September, 1914, amounted to $95,170 as against $79,079 for September, 1913. The bulk of these cars came from Italy, which sent over forty machines. The same country sent only sixty-six for the 9 months ending September.

France sent over seven cars during September, 1914, valued at $24,650. The United Kingdom during the same month sent over nine cars valued at $19,537, just three better than September, 1913. The French imports were six less than the same period in 1913.

Market Reports for the Week

This week's market reports showed no important changes. These were few and small. A few of the markets have shown a lowering demand during the past week, especially the metals. Though tin went up $0.13 per 100 pounds, this metal showed less demand for future positions. Both coppers were held more firmly this week, but the demand was small. Lead remained quiet but steadier in the open market. Antimony, though strong at the beginning of the week dropped on Friday to $0.13 1-2. This product is less active and less strong at the closing. There were no changes in the oils and lubricants markets. An easier tone developed in the rubber markets on Tuesday. This was due to the announcement of the destruction of the German cruiser Emden. The prices were generally 1 to 1 1-2 cents lower for all grades. Up-River Para dropped to $0.65. Trading was quiet in this market. Stocks of rubber at Para and Manaos in first and second hands on November 1 were 1,500 tons smaller, it was stated, that on the same date last year.

Boston's Electric Salon a Success

Exhibitors Well Pleased with Results—Some Sales —Dates for Other Shows

BOSTON, MASS., Nov. 9—Boston's second Electric Automobile Salon ended tonight and all exhibitors reported that they were very well pleased with the results. Throughout the week there was a good attendance, and various features were arranged to attract people who would appreciate electrics. With the $1 admission there was not a throng at any time, and so the visitors had a chance to inspect the machines very thoroughly. Under the rules there was no open solicitation of orders. And when a visitor finished looking over one make the salesman introduced her to the man in charge of the next exhibit. But some sales were closed during the week. President Louis S. Gibbs of the Electric Motor Car Club said that all the exhibitors expressed themselves as well satisfied and that they would be glad to exhibit again if the club has another Salon. So it is now assured that the exhibition will become an annual affair. The club is working hard to remove the restrictions in the down town section relative to traffic and parking of motor cars, and if it is successful the sales of electrics will be very much larger in Boston.

59 Exhibitors at Providence Show

PROVIDENCE, R. I., Nov. 9—The sixth annual automobile show to be held in Providence will open on November 14 and continue until the following Saturday.

The show, which will be held in the armory, will have this year thirty-five passenger car, twelve commercial vehicle and twelve motorcycle and accessory exhibitors. Forty-four separate makes of passenger cars will be shown, while the number of commercial vehicles will be fifteen.

The Providence Dealers Assn. is promoting it, and P. S. Clark, who was in charge of last year's show, will again be general manager.

Milwaukee Show Dates Are Jan. 8-14

MILWAUKEE, WIS., Nov. 7—The seventh annual Milwaukee show, and the fifth to be held under auspices of the Milwaukee Automobile Dealers' Assn., will be held in the Auditorium at Milwaukee, beginning Friday evening, January 8 and closing Thursday evening, January 14. The Milwaukee show opens on the heels of the metropolitan show in New York and practically co-incident with the Philadelphia show, neither of which are near enough to interfere with the local exposition in matter of attendance or securing of exhibits.

No Building Large Enough for Detroit Show

DETROIT, MICH., Nov. 9—The annual automobile show promoted by the Detroit Automobile Dealers' Assn. will be held the week of January 16. No building has as yet been decided upon.

Philadelphia Show Jan. 9-16

PHILADELPHIA, PA., Nov. 7—At a meeting of the Philadelphia Automobile Trade Assn. in the headquarters, it was decided that the 1915 exhibition will be held in the Metropolitan building, Broad and Wallace streets, the same as last year. The dates are January 9 to 16 inclusive.

William P. Herbert, president of the association, will be chairman of the Show committee, and his associates are R. M. Cook, E. C. Johnson, J. E. Gomery, E. B. Jackson and H. Warren Terry, the last-named being secretary of the committee.

Railroad Classification Committee Visits Plants

DETROIT, MICH., Nov. 10—Having expressed the desire for a preliminary conference with the automobile industry through the National Automobile Chamber of Commerce in the matter of automobile loading and weights, the entire Uniform Classification Committee of the railroads visited Detroit last week with the Traffic Committee and Traffic Manager of the N. A. C. C., and devoted 2 days to visiting the factories.

This is of particular importance as the Uniform Classification Committee will rewrite the classification of automobiles and parts as to package requirements, minimum carload weights, articles on which carload ratings will be granted, etc., and their recommendation is likely to be adopted by railroads in Western, Southern and Official classification territories, to take the place of the separate classifications now prevailing.

The dunnage allowance of 500 pounds per carload has been discontinued on all freight, including automobiles, and the railroads now propose to charge $1 per vehicle on automobile carloads, or less than carloads, when labor, materials for blocking and bracing in cars is furnished by carriers.

Nuckols Director in Valvoline Oil Co.

NEW YORK CITY, Nov. 9—Henry W. Nuckols, formerly president of the Columbia Motor Car Co., and now connected with the Packard Motor Car Co., Detroit, has purchased an interest in the Valvoline Oil Co., and will become a director and administrative officer in that company with headquarters at 11 Broadway. He will take up his duties immediately. This company has its refineries at Butler and Warren, Pa., and Edgewater, N. J.

NEW YORK CITY, Nov. 9—L. H. Kittredge, president of the Peerless Motor Car Co., Cleveland, O., sailed last week for Europe, where he is studying the motor truck situation. Sailing on the *Lusitania* with Mr. Kittredge was I. M. Lewis, general manager and treasurer of the Bessemer Motor Truck Co., Grove City, Pa.

Industrial Group to Improve Conditions

NEW YORK CITY, Nov. 6—Last spring the Exhibit of Better Industrial Relations was given under the auspices of the Business Men's Group, which is being reorganized and will hereafter be known as the Industrial Group of the Society for Ethical Culture.

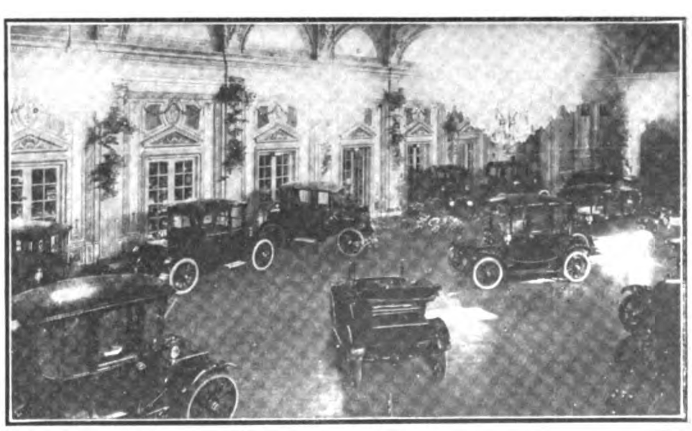
Grant Six with Electric System for $795

DETROIT, MICH., Nov. 11—*Special Telegram*—The Grant Motor Co., Findlay, O., has announced a six-cylinder model to sell at $795. It has 106-inch wheelbase, standard tread and is equipped with a 2 7-8 by 4 1-4-inch block motor.

Other specifications are three-speed gearset, floating rear axle, left drive, center control, cone clutch, cantilever rear spring suspension, unit electric motor generator for lighting and cranking and cowl gasoline tank.

The car carries complete equipment, but if desired, can be had for $45 less without electric cranking and lighting. When so fitted, acetylene lights are furnished. The body is a five-passenger type of sloping lines.

The addition of this car to its output will not interfere with the making of the small four-cylinder roadster at $425, which has up to this time, been the single product of the Grant company since it started in business 2 years ago. It is probable that additions to the plant will be made during the coming year to take care of increased reduction, due to the bringing out of the six, according to the Grant concern.



View of Boston's second electric Automobile Salon

Oldfield Leads in Desert Race

Arrives at Prescott on Second Leg of 671-Mile Contest—Covers 236 Miles in 9:20

PRESCOTT, ARIZ., Nov. 10—*Special Telegram*—Barney Oldfield in the Los Angeles-Phoenix race arrived first at the night control at Prescott at 2:52. His time from Needles, Cal., was 9 hours and 20 minutes, the distance being 236 miles. Olin Davis, who was fourth at the Needles control, arrived second at Prescott in 9 hours, and 32 minutes. Nikrent advanced from sixth position at Needles to third, his elapsed time being 9 hours, 30 minutes. Both Nikrent and Davis arrived at 3:08 p. m.

NEEDLES, CAL., Nov. 9—Barney Oldfield, at the wheel of a Stutz was first at the initial night control in the Los Angeles-Phoenix desert race, completing the 301.4 miles in 8:45:55; R. C. Durant in a Chevrolet was second in 8:51:54; Beaudette in a Paige, was third in 9:14:55; Davis, Simplex, was fourth in 9:19:30; Louis Chevorlet was fifth in 9:24, and Nikrent in a Paige was sixth in 9:25.

Two cars already are out of the race. Pink, in a Thomas, went into the ditch 15 miles out of Los Angeles and the car was driven 100 miles further by mechanician Tom Ely before going out. Sprague at the wheel of a Dietrich also was wrecked but not badly hurt.

On November 10 twelve will start on the second run to Prescott, a distance of 236 miles. The final leg of the race is from Prescott to Phoenix, Ariz., the total distance being 671 miles.

LOS ANGELES, CAL., Nov. 9—Twenty cars were sent away at 5:30 Monday morning, November 9, in the seventh annual Los Angeles-Phoenix road race and for three days their drivers will battle for supremacy over a course 671 miles long, or 132 miles longer than any previous desert race. The starters follow:

DRIVER	CAR	DRIVER	CAR
Beaudette	Paige	Snow	Metz
L. Chevrolet	Chevrolet	Taylor	Alco
Schnack	Ford	Foulke	Metz
Davis	Simplex	Ellis	Buick
Oldfield	Stutz	Sprague	Dietrich
Anderson	Kissel	Burns	Stutz
Carlson	Maxwell	Pink	Thomas
Nikrent	Paige	Bramlett	Cadillac
Wing	Metz	R. C. Durant	Chevrolet
Greenwood	Kincaid Sp.	DuBois	Cole

The course over which this year's race is run is an entirely new one and on the whole better road conditions obtain than was the case last year.

The first part of the race from East Lake Park to San Bernardino is practically all a concrete boulevard and the distance is 61 miles to the first checking station. The first night stop is at Needles, on the banks of the Colorado.

The second night control is at Prescott, Ariz., just 134 miles from the finish line of Phoenix, Ariz. Thence, the road leads by a winding way to an elevation of 7,000 feet and then drops down to Skull Valley, 18 miles out of Prescott. There are two routes from Wickenburg to Hot Springs Junction, the one through Tub Springs being 19 miles in length and the other through the Garden of Allah being 16 miles. Weather conditions will determine which of the two is chosen.

Under almost any weather condition, nearly every variety of roads are to be encountered on the race and though the race is hard enough when the sun shines, the difficulties to be overcome in the event of rain are sufficient to entitle the driver to all the plaudits he wins.

The checking stations together with their distances from the starting point follow: San Bernardino, 61; Victorville, 102; Barstow, 136; Needles, 301.4; Kingman, 368.4; Ash Fork, 479.4; Prescott, 537.4; Wickenburg, 609.4; Phoenix, 671.4.

Pope-Hartford Breaks El Paso-Phoenix Record

PHOENIX, ARIZ., Nov. 9—Beating twenty-eight other starters, and lowering the record for the trip by more than 2 hours, Hugh Miller, at the wheel of a Pope-Hartford, today won the El Paso-Phoenix road race of 533 miles in 14:37. Miller averaged nearly 37 miles an hour. J. T. Hutchins (Buick) was second, in 15:57, and C. W. Tucker (Stutz) was third in 16:40. Miller's performance is all the more praiseworthy because of the fact that his car overturned yesterday near Bisbee. Neither he nor his mechanician were hurt, however.

500-Mile Race Date Is May 29

INDIANAPOLIS, IND., Nov. 7—The Indianapolis motor speedway's 1915 racing campaign will open next week, with the distribution of entry blanks for the next 500-mile race, it is announced today. The date of the race will be Saturday, May 29, Decoration day next year falling on Sunday, and the piston displacement limit will be 300 cubic inches.

Several factories, including Stutz, Maxwell and Mercer, are known to have 300-inch machines already under construction, so that no difficulty in filling the entry list is anticipated. Foreign entrants, of course, will be few, being limited to such drivers as are ineligible for army service or are natives of countries not at war, such as Italy.

Corona Entries to Date Number 11

CORONA, CAL., Nov. 10—Indications are that twenty-five entries will be made for the Corona road race on Thanksgiving. To date eleven entries have been made. These are as follows:

CAR	DRIVER	ENTRANT
Stutz	Klein	W. M. Brown
Stutz	Anderson	W. M. Brown
Stutz	Oldfield	W. M. Brown
Ono		Frank Young
Mercer	Pullen	Pacific Coast Mercer Agency
Mercer		Pacific Coast Mercer Agency
Mercer		Pacific Coast Mercer Agency
Peugeot		Harry Grant
Sunbeam		Harry Grant
Sunbeam		Harry Grant
Mercedes	De Palma	De Palma

Grand Prix Date Changed to Feb. 27

SAN FRANCISCO, CAL., Nov. 9—There will be no 2 weeks' delay between the Vanderbilt Cup and the Grand Prix automobile races that are scheduled as Panama-Pacific International Exposition attractions.

At a meeting of the racing committee of the exposition it was decided to set forward the date of the Grand Prix race to Saturday, February 27, instead of March 6. This will make this international event take place 5 days after the Vanderbilt Cup contest, which is to take place Monday, February 22.

The reason for the change is that many of the racing drivers who have signified their intention of entering the races protested that the time between the original dates was too long and would prevent them from competing in other races about the country. The two automobile classics are expected to attract hundreds of thousands to the course, which is admitted to be one of the best in the country. The best known drivers in America have signified their intention of entering, and the racing committee looks for some very fast time to be made.

Road Race Planned for Oklahoma City

OKLAHOMA CITY, OKLA., Oct. 30—The Southwestern Racing Assn. expects to conduct a road race on Friday, May 1, on a course in the outskirts of Oklahoma City. The course is 9.3 miles in length and the race for thirty laps, or 280 miles. It is to be a free-for-all, and known as the Southwestern Sweepstakes. The prizes are to be as follows: First, $5,000; second, $2,500; third, $1,500; fourth, $750 and fifth, $500.

The course is roughly D-shaped with two legs in the outskirts of the city and the curved part a portion of the boulevard system. It is in the outskirts on the northeast corner of the city. The boulevard section of the course, approximately 5 miles, is 100 feet wide, and in good condition. This road was built by a bond issue and is well maintained. The remainder of the course or the other two legs is on outlying city streets. One leg, known as the south, is a part of the Savannah-Los Angeles cross-country road, and is known as East 23d street in the city. The other leg, known as the west, is a part of the Winnipeg to the Gulf Highway and is about 50 feet wide. There are few houses on these two legs, not more than eight or ten on each.

Overland Stromberg-Equipped Makes 29 M.P.G.

CHICAGO, ILL., Nov. 9—A 1915 Overland Model 80, equipped with a Stromberg carbureter, made a fuel economy and all-around-efficiency test Monday, November 9, in Chicago, under A. A. A. sanction; it went 29 miles on a gallon of gasoline, throttled down to 5 miles an hour and speeded up to 45 miles on high, accelerated to 30 miles from a standing start in 13 3-5 seconds, and climbed Hubbard's Hill from a standing start, finishing at 20 miles an hour. The car with five passengers weighed 3,930 pounds, giving a ton-mileage of 56.84.

PHILADELPHIA, PA., Nov. 8—The Fletcher Cup Run, postponed from last spring, was conducted today by the Automobile Club of Philadelphia, and G. W. B. Fletcher, driving a Buick, was the winner. R. P. Brown in a Packard was second. Eleven cars finished.

Los Angeles Section E. V. A. A. Meets

LOS ANGELES, CAL., Nov. 4—The fourth monthly meeting of the Los Angeles section, Electric Vehicle Assn. of America, was held in the banquet room of the Jonathan Club here this evening. Since the organization of the local branch of the electric body, 4 months ago, the Los Angeles branch has grown to be the fourth largest chapter in the association, with a membership of fifty-four. The meeting tonight was preceded by a dinner which was attended by the entire membership. After the banquet a short business session was held, after which papers on the electric vehicle industry were read.

Radiation Indianapolis S.A.E. Subject

INDIANAPOLIS, IND., Nov. 11—"Radiators and Their Relation to the Motor Car" was the topic discussed at the meeting of the Indiana section of the Society of Automobile Engineers last night. The reasons for overheating of motors and the method of preventing this were taken up. The design of efficient radiators and their construction were also discussed. One of the interesting points brought up was the reason for the V or pointed type of radiator. The paper was given by C. H. Greer, who is chief engineer of the McCord Mfg. Co., Detroit, Mich.

M. A. D. A. Is Reorganized—New Officers

MILWAUKEE, WIS., Nov. 7—The Milwaukee Automobile Dealers' Assn., which promoted the Vanderbilt Cup and Grand Prix races in Milwaukee in October, 1912, and has promoted the annual Milwaukee motor show since the Milwaukee Automobile Club relinquished the management of the exposition in 1910, has been reorganized with Frank J. Edwards, head of the KisselKar Co. and Edwards Motor Co., Milwaukee, as president. All of the old officers have retired, Isaac G. Hickman, president for the past 3 years, having gone out of the automobile business with the establishment of a direct factory branch in Milwaukee by the Ford.

DETROIT, MICH., Nov. 6—At a meeting of the creditors of the Benham Mfg. Co., held yesterday, it was suggested that the Union Trust Co., be appointed trustee of the property and that steps be taken for the disposal of the latter. Final action was postponed until November 13, when another meeting will be held.

Truck Makers to Meet at Shows

Both New York and Chicago Will Provide Ample Space—No Exhibits

NEW YORK CITY, Nov. 9—The Board of Directors of the National Automobile Chamber of Commerce is turning its attention more and more to the commercial vehicle industry. Although there is to be no exhibition of trucks this year it was decided at last week's meeting of the board that in the distribution of space at the National Automobile Shows at New York and Chicago, a sort of business bourse will be established with ample facilities for the meeting and transaction of business of the thirty-one members of the Chamber who make commercial vehicles, and their dealers, agents, prospects, users, etc. This will be in the nature of a hotel exchange or lobby. No exhibits will be permitted but every opportunity will be offered to do business.

Reports of shipments during October were very encouraging. The traffic committee of the Chamber stating that during the month of October, 10,225 carload shipments were made, an increase of 2,531 carloads over the corresponding month of 1913.

In attendance at the meeting were: Charles Clifton, Pierce-Arrow; Wilfred C. Leland, Cadillac; C. C. Hanch, Marmon; S. T. Davis, Jr., Locomobile; M. J. Budlong, Packard; W. T. White, White; E. R. Benson, Studebaker; Hugh Chalmers, Chalmers; John N. Willys, Willys-Overland; H. H. Rice, Waverley; H. O. Smith, Premier; W. H. VanDervoort, Moline, and Alfred Reeves, general manager.

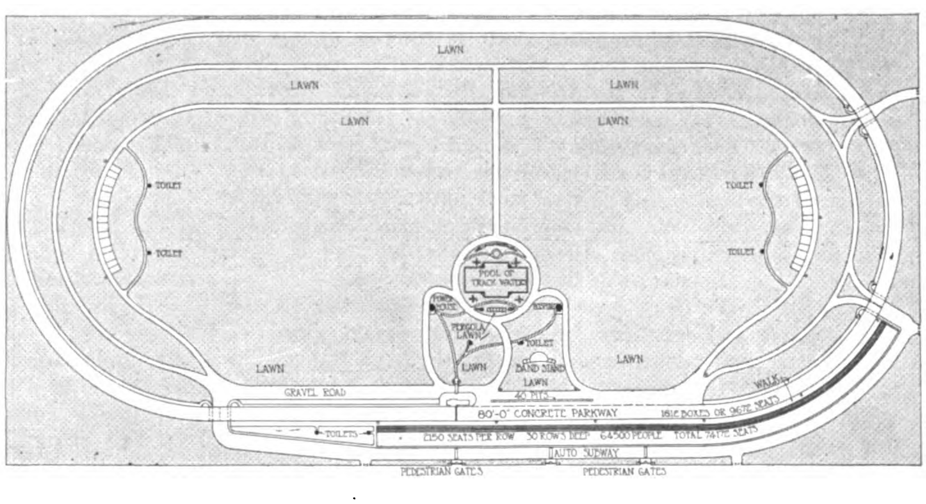
Four Floors for Cars

NEW YORK CITY, Nov. 6—So great has the demand of automobile makers been this season for space at the Fifteenth Annual National Automobile Show in Grand Central Palace, New York, that for the first time four floors of the huge building will be utilized for the display of complete cars. The show is scheduled to open Saturday, January 2, and will continue until January 9. Even with four floors available Manager S. A. Miles and the show committee find that they are unable to accommodate all of the applicants for exhibition space. Heretofore the fourth story of the Palace has been used exclusively for accessory exhibitors, but some of these will be obliged to get along with smaller space than in former years in order to make room for the complete cars.

Already 548 exhibitors are on the list for these two shows, which is an unusually large number and before the doors are open this number will be materially increased. Ninety-two complete car makers are on the list for the New York show and ninety-one for Chicago. Exhibitors are taking over 1,000 square feet more floor space at the New York show this year than last.

Plan of 2-Mile Speedway for Minneapolis and St. Paul

MINNEAPOLIS, MINN., Nov. 7—The new speedway to be built by the Twin-City Speedway Assn., will be a 2-mile platter-shaped track 80 feet wide and having on either side gravel safety zones 32 feet wide. The track will be banked throughout its entire circuit, the banking being 2 per cent. on the straightaways and 35 per cent. on the turns. The radius of the curves will be 2,200 feet. It will be 4.5 miles from the court house in either St. Paul or Minneapolis. It is estimated that the grandstands will seat 76,450 persons and the bleachers an additional 30,000. There will be accommodations within the ground for 100,000 automobiles. The buildings within the oval of the track will be sunk so as not to interfere with the view of people sitting in the parked automobiles around the track.



Holds Headlight Rule Invalid

Milwaukee Judge Decides Ordinance Conflicts with State Automobile Law

MILWAUKEE, WIS., Nov. 9—The city of Milwaukee's earnest effort to curb the dazzling headlight evil has practically been set at naught by a decision of Judge Backus of the municipal court holding the so-called headlight ordinance unconstitutional because it is in contravention to the state motor code.

Early this year the Milwaukee common council asked the Milwaukee Automobile Club to frame an ordinance to prevent the use of brilliant or dazzling headlights within the city limits. This provides that no vehicle may carry a lamp or lamps the main direct rays of which shall strike the roadway more than 200 feet forward from the base of such vehicle on a horizontal roadway. A large number of arrests and convictions resulted. Judge Backus now quotes the state law: "there shall be displayed on the front of every automobile or other similar motor vehicle, while being operated or driven along or upon any public highway of this state, at least one lamp giving a reasonably bright light in the direction in which said automobile or other similar motor vehicle is going * * * and it shall be unlawful for any person to operate or drive any automobile or other similar motor vehicle * * * at such a rate of speed that such vehicle cannot be brought to a complete stop within the distance ahead that the driver or operator thereof can, with the aid of the lights thereon, in connection with the lights from other sources, see an object the size of a person." The state law also provides: "The provisions of this section shall be uniform in operation throughout the state and no city, village, county, town, park board or other local authorities shall have power to enact, pass, enforce or maintain any ordinance, resolution, rule or regulation, requiring local registration or other requirements or in any manner excluding or prohibiting any automobile or other similar motor vehicle, whose owner has complied with the provisions of this section, from the free and unobstructed use of all public highways, driveways and parkways within the state." The Wisconsin Legislature meets again in January, 1915, and in the meantime no efforts will be made to test the decision, as the legislature will take care of the dazzling headlight proposition, according to Milwaukee members.

Municipality Not Liable for Damages

MILWAUKEE, WIS., Nov. 9—A municipality cannot be held liable for damages in personal injury actions based upon accidents caused by motor or other vehicles operated by the fire and police alarm system, according to the opinion and decision of the supreme court of Wisconsin in the case of Engel vs. City of Milwaukee. Engel was injured by being struck by a fire alarm telegraph car and was given damages in the circuit court. The supreme court reverses the decision and upholds the city's contention that the fire and police alarm system is a governmental function. Its apparatus has the same right of way on public thoroughfares as fire apparatus, police patrols, ambulances and United States mail carriers.

Automobilists Win Wheel Tax Test Case

LINCOLN, ILL., Nov. 9—Declaring that a city wheel tax is double taxation and illegal, Judge George W. Patton, of Pontiac, sitting in the Logan county circuit court, set aside the Lincoln city ordinance. His decision held that automobiles, not used for commercial purposes, are exempt from city tax. The law was not questioned in relation to horse-drawn vehicles.

Goodyear Has Made 4,500,000 Tires

AKRON, O., Nov. 9—At the conference in this city, recently, of the Goodyear Tire & Rubber Co., salesmen from all over the country, it was brought out that that company has produced a grand total of 4,500,000 tires in its existence. This company manufactures tire machines in its own plant, which enables it to turn out fifty tires a day per man, compared with an average of five tires a day by hand labor.

Koehler Concentrates on 1-Ton Truck

NEW YORK CITY, Nov. 6—The H. J. Koehler Co. has discontinued selling pleasure cars, having decided to concentrate its efforts in the marketing of the Koehler 1-ton truck built at the Newark, N. J. factory. The truck output should be almost doubled during 1915.

NEW YORK CITY, Nov. 9—Paul Lacroix, Mercedes distributor for the United States, has taken the agency for the Imperial car. His territory includes this city, Long Island, northern New Jersey, southern part of New York State and part of Connecticut, with export rights. The new Imperial agency headquarters will be at the Lacroix showrooms, 3 East 52d street, with a service department at the Mercedes shops, 218 East 54th street.

Stewart Feed Shows 3.4 Miles Gain in Test

DETROIT, MICH., Nov. 7—The Stewart vacuum feed on an Oakland is better than a pressure feed by 3.4 miles to the gallon of fuel, according to an unofficial test made November 9, between Detroit and Ypsilanti, Mich., with a 1915 Oakland Model 37 roadster. On the run toward Ypsilanti, with pressure feed, the car made 25.3 miles on 1 gallon; on the return, with Stewart feed, it made 28.7 miles on 1 gallon. The car and load weighed 2,763 pounds; it was equipped with a Marvel carbureter and Goodyear non-skids.

Dodge Is Streamline Touring Car Selling at $785

(*Continued from page* 883)

vanadium steel and the shafts run on ample ball bearings.

Following the drive back from the gearset, it next goes through a universal of the ring-and-yoke type which is completely inclosed. The propeller shaft is tubular and is inclosed within a torsion tube which takes drive and torque, and which is riveted to the front of the rear axle housing.

The floating rear axle has a pressed steel housing with large plate at the rear giving access to differential and bearings. The differential is carried on the removable front cover portion of the housing. The steel stock used is 3-16 inch thick and the gears are vanadium steel heat treated. Timken bearings are used throughout the axle assembly and in rear wheels. The axle gear ratio is 3.615 to 1.

Mounted on the front cover portion of the housing are the brake shafts and equalizers, allowing the operating rods to run forward to the controls about centrally of the frame. The service brakes contract on the 12-inch rear wheel drums, while the emergency set expand internally. The drum width is 2 1-4 inches.

Chrome vanadium steel self-lubricating springs support the frame, the front set being half-elliptic and the rear three-quarter. They are overslung on the axles. The spring dimensions are: Front, 35 13-16 inches long by 1 3-4 inch wide; rear, 43 inches long by 2 inches wide.

The frame is well-braced with three cross members, and is pressed from 5-32 inch stock into channel section 3 1-2 inches deep. There is a kick-up at the rear to clear the axle, and the front bottle necks, allowing the car to turn in a 40-foot circle.

The steering gear is of the irreversible nut-and-sector type controlled by a 17-inch wheel. The spark and throttle control levers are placed on a sector under the steering wheel.

The round 15-gallon gasoline tank is hung at the rear by forged brackets and the feed to the carbureter is by air pressure maintained by a camshaft pump. The instrument board carries a hand pump for auxiliary air pressure on the fuel in this tank.

Tread is standard 56-inch with the option of 60-inch.

FORD Adds Canadian Plant—By the opening on November 2 of a large and modern assembling and repairing plant at Laurier and DeGaspe avenues, Montreal, Que., the Ford Motor Co. of Canada will have brought the total number of its large branches of this kind in the Dominion to eleven and employment will be given in the plant to about 200 men, most of whom will be Montrealers, though a few more of the expert mechanics will be brought from Ford, Ont., where the Canadian company has its factories and headquarters. The new plant, which faces on Laurier avenue, has been erected at a cost of $300,000 and covers an area of 160 by 150 feet. While the building is at present but four stories in height, it has been so solidly constructed that it will be possible to add six more floors, the structure having been designed with this end in view. A novel feature of the plant is a flat concrete roof surrounded by a parapet for testing the cars after they have been assembled or repaired. The two big freight elevators run up as far as the roof through a tower erected at one corner so as to admit of the automobiles being brought up. Access by rail to the plant has been attained by the building of a spur from the C. P. R., and special facilities have been provided for unloading, dumping coal, etc.

Williams Tire Purchases Land—The Williams Tire Co., Vista, Pa., has purchased 10 acres of land upon which it will erect a plant.

May Start Plug Plant in Rockford—Arthur Bergstrom, inventor of the Bergie national spark plug, may start a manufacturing plant in Rockford, Ill.

New Plants for Aluminum Goods—The Aluminum Goods Co., Two Rivers, Wis., has taken occupancy of two new brick factory buildings erected during the past summer and will increase its capacity from 40 to 60 per cent.

Hartford Rubber Works Resume—The Hartford Rubber Works, Hartford, Conn., which has been running with a small force since the outbreak of the war, resumed, in part, recently. The entire plant is expected to be running full force soon.

Special Machinery for Abbott Ball—The Abbott Ball Co., Hartford, Conn., has perfected special machinery whereby it is able to turn out balls of all sizes, from 1/8 inch to 1/2 inch in diameter, and will later be in a position to furnish all other sizes.

Kelly Truck's New Additions—The Kelly Motor Truck Co., Springfield, O., has awarded contracts for the erection of two large additions to its plant. The additions are necessary because of the rapid increase in the business of the concern. One of the additions will be 260 by 50 feet and the other 100 by 60 feet.

Golden West's New Factory—The Golden West Motors Co., Sacramento, Cal., has erected and equipped a factory 150 by 300 feet and a pattern shop for the manufacture of motor trucks. It will begin the construction of a third building, and is figuring on buying a number of automatic high-speed machinery shortly.

Wayne Tank Working Full Force—That the Wayne Oil Tank Co., Fort Wayne. Ind., has the best of an outlook for the future was the statement of several of the factory officials given out recently. The boiler department and the shipping department are both working their full force 10 hours a day. All of the other departments are working their full force 8 hours per day.

Blodgett Plant Ready for Work—Within a short time the Blodgett Rubber Co., St. Joseph, Mich., will have its plant in full running order. For several weeks the machines to be used in the manufacture of the new process inner tubes for automobiles have been arriving in St. Joseph for installation in the plant. The old plant of the Blodgett company in Warren, O., has been removed to St. Joseph.

J. I. C. Builds Garage—The J. I. Case T. M. Co., Racine, Wis., is building a large garage at its administration building for the exclusive use of the officers and employees of the company. Up to this time officers and employees have been obliged to leave their cars in streets and alleys near the large office building, which is some distance from the main works, throughout the day, winter and summer.

Chevrolet May Add New Plant—Property covering about five city blocks, surrounding the plant of the Chevrolet Motor Co., Flint, Mich., has been purchased by President W. C. Durant, of that company. It is rumored that this purchase was made with the intention of adding a new plant, which is to have more than double the floor space of the present plant, and which will permit in time an annual output of 20,000 cars.

Paint Shop for Maxwell Plant—The Maxwell Motor Co., Detroit, Mich., is enlarging its factory space to make room for the increase in material and manufacturing. A circus tent was set up on the Maxwell factory grounds in Detroit as a temporary paint shop, where only axle housings were painted. The tent is soon to be taken down, however, for beside it has been constructed a mammoth building to be used for painting and enameling work only. The building is 300 feet long and 150 feet wide. It is modern in every way, having steel construction throughout, cement bases and floor, with walls of yellow brick.

April............Calumet, Mich., Show, Coliseum.
May 29...........Indianapolis, Ind., 500-Mile Race, Indianapolis Motor Speedway.

The Week in  the Industry

Motor Men in New Roles

RACING Drivers Retire—"Johnny" Minker, formerly of York, Pa., but for the past 2 years a resident of Richmond, Va., was in York recently and stated that he had decided to give up the automobile racing game. Minker for a number of years has been a well-known driver of racing cars, being connected with the Kline Motor Car Corp. He has resigned that position and opened a garage and service station at Littlestown, Pa., with L. E. Alleman as a partner. George Benedict, well known in automobile racing circles as mechanician for Burman, Teddy Tetzlaff and other racing stars, has retired from the sport. It is a strange coincidence that his former companion, Tetzlaff, has also said farewell to the hazardous pastime.

Paterson Pres. Carriage Assn.—W. A. Paterson, the automobile and carriage builder, has been appointed a vice-president of the Carriage Builders' National Assn., Flint, Mich.

Grant Goes West—Harry Grant, the well-known driver, left Boston recently for the Pacific Coast, where he will drive the Sunbeam in all the big races held in California during the winter.

Fuller Gets Elected—Alvan T. Fuller, who has the Packard agency for Boston, Portland and Providence, was elected a member of the Legislature from Malden, Mass., last week on the Bull Moose ticket.

Paint Expert Promoted — William Rauschenberger, paint and varnish expert of the Studebaker Corp. plants in Detroit, Mich., has been assigned charge of similar operations in the company's South Bend works as well.

Simonds Leaves Maguire — Frank Simonds, for several years in charge of the service station of the J. W. Maguire Co., Boston, eastern Massachusetts agent for Pierce-Arrow cars, resigned last week to go into business for himself in Brookline, Mass.

Graves Cartercar Chief Engineer—H. S. Graves has been made chief engineer of the Cartercar Co., Pontiac, Mich. He has been associated with the company for the past 2 years. Prior to that time he was connected with the E. R. Thomas Motor Co., the Buffalo Gasoline Engine Co. and the Studebaker and Maxwell companies.

Campion Resigns; Joins Marathon—Ed L. Campion, for 13 years a member of the Firestone Tire & Rubber Co. sales organization, has resigned as manager of the Seattle, Wash., branch to accept the position of sales manager of the Marathon Tire & Rubber Co., the offices of which are at Cuyahoga Falls, O. Campion's successor has not yet been named.

—

Garage and Dealers' Field

Pillaging Automobiles in Mexican City—The private garages of hundreds of wealthy refugees and other residents of the City of Mexico, Mexico, have been pillaged of automobiles during the last several weeks. Many cars were also confiscated by army officers and Federal employees.

King Agency's New Sales Plan—The King Motor Car Sales Co., Detroit, Mich. distributors for the King cars in the state of Michigan, has recently started selling on time payments. Under the present general conditions it has been deemed advisable to extend time to customers of good standing and thus from 30 to 90-day notes are accepted.

Planning Many Service Stations—In anticipation of a tremendous volume of tourist travel north and south along the Pacific Coast, automobile branches and distributing agencies are laying plans for the operation of a chain of service stations from the Canadian border to the Mexican boundary. Motor touring over the Pacific Highway and the routes from the country east of the Coast range is expected to break all records. The expositions at San Francisco and San Diego, the opening of new highways and the closing of European countries to tourists will combine, it is predicted, to send thousands of automobiling enthusiasts to the Western Slope in 1915.

Auction Co. in Boston—The Boston Auto Sales and Auction Co. has been formed in Boston with J. R. McPherson as president and J. M. Barry as treasurer, and a large building at the corner of Brighton and Commonwealth avenues has been leased, where every Tuesday morning at 11 o'clock automobiles will be sold at public auction. It is the first time that a company has been formed exclusively for this purpose in Boston. All cars will be sold subject to a return in 48 hours if the machines are not as represented by the owners' guarantee. Every owner turning in a car will have to give a written guarantee as to the condition of the car, and the company will have men examine it to see if this is true.

Peerless Establishes Agencies—The Peerless Motor Car Cos., Philadelphia, Pa., and Boston, Mass., have decided to discontinue their branches and hereafter will be handled as agency propositions. In Boston this new plan will mean the discontinuance also of the Rauch & Lang Electric Co.'s branch. The electric company has taken charge of the office there and has sent on its own men from Cleveland to handle the product as a branch. The Beacon Motor Car Co. has been organized to handle the Peerless in Boston, while the Girard Automobile Co. will handle it in Philadelphia at 2314 Chestnut street, in charge of R. W. Cook. The Peerless and the Rauch & Lang will occupy the same building in Boston at 660 Beacon street. J. L. Snow, manager of the branch, will continue at the head of the Beacon Motor Car Co. Sub-agencies will be established throughout New England for the Peerless line.

Motor Bus Lines Thrive in Wash.—The effect of motor bus lines operating in competition with electric interurban systems is shown in a special report filed with the Public Service Commission of the State of Washington by the Puget Sound Electric Co., covering its line between Seattle and Tacoma, a distance of approximately 40 miles. The report shows that the local passenger business dropped from 226.471, handled in August, 1913, to 99,484 during August, 1914, a loss of approximately 125,000. The through passenger business remained about the same. A big fleet of motor trucks of both passenger and freight carrying types is operated from Seattle to the valley points, and it is so liberally patronized that the electric interurbans are losing business. Last June the traction corporation increased its rates between local points, and then sprang up motor bus lines. The result has been that a loss of more than $8,000 in passenger fares in August alone was suffered.

Accessories for the Automobilist

RED Head Spark Plugs—Two new Red Head spark plugs, Figs. 1 and 2, have been announced by the Emil Grossman Mfg. Co., Bush Terminal, Brooklyn, N. Y. One is designed for modern operating conditions caused by higher speed, higher compression motors. One hundred dollars has been offered as a prize for a suitable name for this plug. The porcelain is a high insulating body of substantial size. Cement is poured into the space between the porcelain and the internal threads of the shell, and the entire plug is then baked by a secret process. No bushings or gaskets are used. The terminal screw is sunk and baked into the porcelain; it cannot be twisted off when pliers are used to tighten the terminal. The sparking points are heat-resisting nickel steel and will not burn away, it is stated. The shell electrode is formed to keep oil away from the sparking points. This plug is made in all sizes and sells for 75 cents.

The other new plug is a priming plug for Ford cars. A plug of this type is of especial service in Winter when the motor requires priming to facilitate starting. The porcelain is straight-sided and will not crack. It is held in place by a large steel bushing which gives ample gripping surface for any wrench. The long body shell overcomes the depression in the cylinder head, the large priming cup allows a free flow of the gasoline, and the heavy meteor wire firing points prevent burning away of the firing points. The price with either porcelain or mica electrode is $1.25.

Braender Non-Skid—The Braender Rubber & Tire Co., Rutherford, N. J., has put upon the market a new and improved non-skid tire.

The new tread, as shown in Fig. 4, is of the combined raised and depressed type. It retains all the advantages of the original Braender Bull Dog Non-Skid with the well-known fishtail cross bars, but has in addition six heavy webs of rubber so placed between the cross bar projections as to give considerably more rubber on the tire, with more tread surface to take the wear.

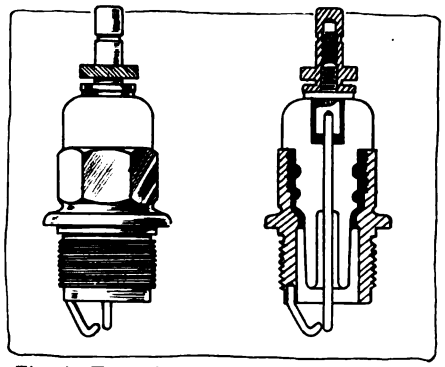

Fig. 1—Two views of new Red Head spark plug for which $100 has been offered for a suitable name

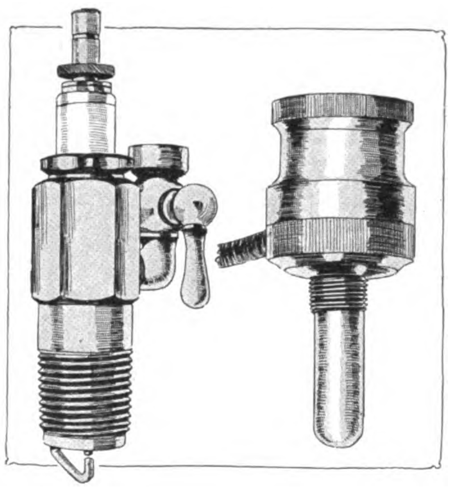

Fig. 2—Left—New Red Head Ford priming plug. Fig. 3—Right—Andersen storage battery regulator

The addition of the webs overcomes any tendency to side skidding on muddy roads or slippery pavements, it is said, and in combination with the cross bars insures a continuous and smooth riding surface, effectually preventing the wear that rounds the edges of ordinary projections while still retaining all the advantages of an efficient non-skid.

The webs, moreover, are so placed as to relieve the strain heretofore borne by the cross bars alone, while strengthening them and distributing the wear evenly over the entire surface of the tread.

Each depression between the bars and webs has a vacuum grip on the road, formed and released by the rolling tire without waste of power or injury to the road.

Fig. 4—Braender Bull Dog non-skid tire

Anderson Regulator—To prevent the injury of the battery by overheating while charging the Economy Electric Co., Economy, Pa., has brought out a temperature regulator, Fig. 3, which reduces the charging rate as the temperature rises above 100 degrees Fahrenheit. The reduction is in proportion to the rise in temperature. Temperatures much above 100 degrees are harmful to a battery and by the use of this instrument this danger is safeguarded. The device, which is known as the Anderson regulator, is guaranteed for 1 year and sells for $3.50. It is simply installed by removing the vent plug. The wiring diagram is shown in Fig. 5.

1915 Mayo Pumps—Two new pumps have been announced by the Mayo Mfg. Co., 60 East 18th street, Chicago, Ill. One is a spark plug pump for Ford cars, Fig. 7, and the other is an impulse pump which is permanently attached to a valve cap, Fig. 6. These pumps will be ready for delivery on Jan. 2. The former is a diminutive spark plug pump built especially for the Ford car and sells for $8 complete. The latter lists at $15.

The Mayo Valve Cap pump requires no fitting other than the drilling and tapping of a 1 3-8-inch hole in one of the valve caps, the screws having 24 threads to the inch. The pump attachment is then screwed into place and the job is completed. It is stated that any machinist

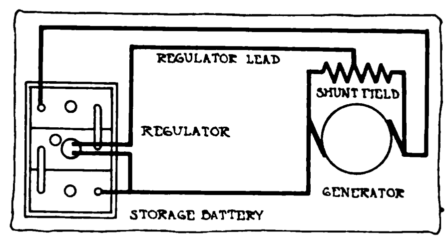

Fig. 5—Wiring diagram, showing installation of Andersen regulator

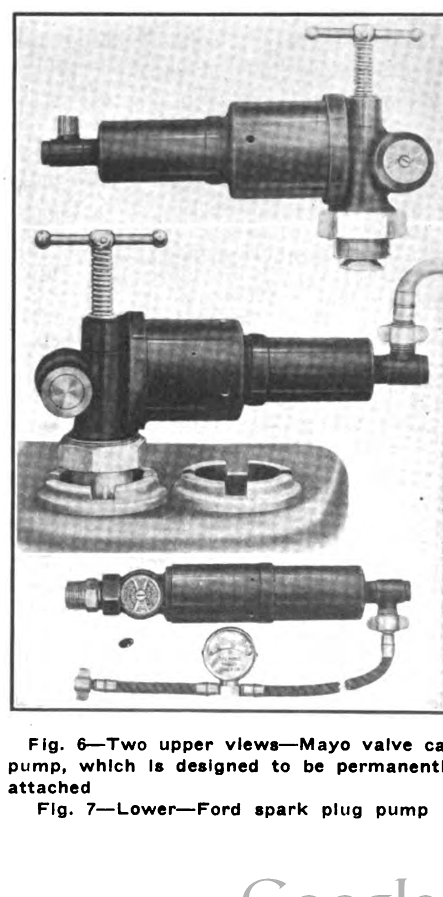

Fig. 6—Two upper views—Mayo valve cap pump, which is designed to be permanently attached

Fig. 7—Lower—Ford spark plug pump

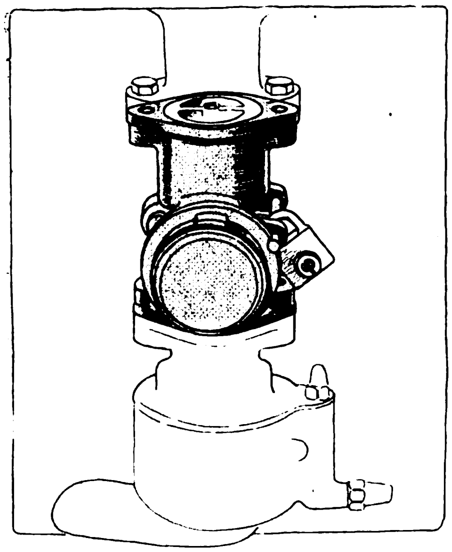

Fig. 8—Kramer self-contained engine governor, which is placed between the carbureter and the intake pipe

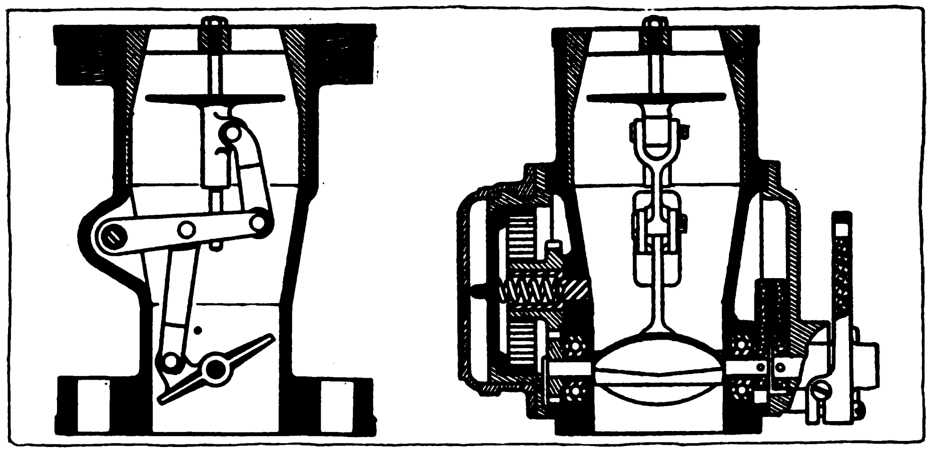

Fig. 9—Sections through Kramer engine governor showing operating disk which is raised or lowered according to the speed of the incoming gases, thus opening or closing the butterfly valve below

can do the work in 1 hour. To operate the pump the handle at the top is depressed and given a quarter turn while the motor is running. This opens the poppet valve shown at the bottom and allows the pump to operate.

A gauge is installed in the hose to indicate the pressure during inflation. A 34 by 4-inch tire can be inflated to 75 pounds pressure in 3 minutes. The maximum pressure obtainable is 150 pounds. The hose may be removed after the tire is inflated, and stored in the tool box.

The Ford pump will inflate a 32 by 3 tire to 65 pounds pressure in 2 minutes and a 32 by 3.5-inch tire to 70 pounds pressure in 3 minutes.

This pump is attached by removing any convenient spark plug, the pump being screwed into its place but not tightened with a wrench. It is furnished with 10 feet of hose and an accurate gauge.

Guide No-Glare Mazda—To eliminate the headlight glare the Guide Motor Lamp Mfg. Co., Cleveland, O., has put on the market a new type of lamp in which the desired end is attained by a special treatment of the upper half of the bulb so that glaring rays from this part are eliminated, the rays being reflected downward and softened. The price of the regular 6-volt, 16-candlepower type is $1.60 per pair. The same price is charged for 6-volt, 12-candlepower Ford lights, and for electric-vehicle work 90-volt lamps of 16 candlepower are furnished for $2.40 per pair. Other candlepowers and voltages may be had on order.

Percama Top Cleaner—A liquid cleaner for mohair tops, seat covers, and similar parts, has just been brought out by the Perkins-Campbell Co., Cincinnati, Ohio, under the name of Percama. It is claimed that substance will remove grease and oil as well as all dirt from seat covers, tops, etc., and will not cause fading of the material. It is sold in quart cans at 25 cents and also in half-gallon and gallon containers.

J. & B. Bulb Carrier—A carrier for extra lighting bulbs is being manufactured by the J. & B. Mfg. Co., Pittsfield, Mass., under the name of the J. & B. It is in the form of a cylindrical cardboard box with a screwed-on cover at each end, the extra bulbs being carried in the covers. The under side of each cover is fitted with a bayonet base, for holding the bulb. The carrier is 5 1-4 inches long and sells for 25 cents.

Bowser Safety Book—A book entitled, Bowser First—Safety Always, has been issued by S. A. Bowser & Co., Fort Wayne, Ind., dealing with the question of safe gasoline storage. Tests of Bowser outfits under various conditions are described and illustrated and accounts of garage fires where these outfits have not been affected by the flames or heat are given.

One test showed the impossibility of exploding the gasoline in a storage tank. A fire was built directly under the tank and kept burning for a considerable length of time. All the gasoline evaporated from the tank but no explosion resulted. In another test the increase in pressure when subjected to heat was determined. A fire was built under a tank full of fuel and the pressure read from time to time. The highest pressure registered was 11.5 pounds, due to the fact that the tank is fitted with an air vent protector which relieves the pressure and acts as a safety valve.

Anti-Freezing Compounds

Horsey Anti-Freeze Solution — The anti-freezing solution made by the Horsey Mfg. Co., 6104 Euclid avenue, Cleveland, O., will not freeze in any climate, it is stated. It will last all season, and in addition to cooling the motor prevents rust and corrosion and lubricates the pump, it is claimed. The color is green in order that a leak may be easily detected. One gallon of the liquid is added to 2 of water. The price is $1 a gallon.

Thermite — The solution known as Thermite, manufactured by the Northwestern Chemical Co., Marietta, O., is guaranteed to remain liquid at 70 degrees below zero when used undiluted. However, under ordinary circumstances it is not necessary to provide for a temperature as low as this, and therefore water may be added, the amount depending on the freezing point desired. A curve, Fig. 10 has been plotted, showing the amount of water to add to give any freezing point between 32 degrees above zero and 70 degrees below. Thus it is a simple matter to make a solution which will meet local climatic conditions. It is stated that Thermite is non-evaporating and that therefore one application is sufficient for all Winter and that it will not injure the cooling system in any way. It sells for $1.25 per gallon.

Jewel Non-Freezing Solution — Denatured alcohol and refined glycerine are the materials used in the solution made by the Wadsworth-Howland Co., Chicago, Ill. This solution is known as the Jewel and is put up in 1 and 5 gallon cans. Water is added to the clear solution, the amount depending on the freezing point desired. For temperatures to 10 degrees above zero 1 quart of the solution is used in 1 gallon of water; to 5 degrees below zero 1.5 quarts to 1 gallon of water; for 20 degrees below zero, 2.5 quarts of solution to 1 gallon; to 34 degrees below zero 1 gallon of solution to 1 gallon of water.

Frezenot—A radiator liquid that will not freeze until a temperature of 54 degrees below zero is reached is made by the Rub-On Mfg. Co., 87 Brayton street, Buffalo, N. Y., under the name of Frezenot. It is sold ready mixed. A barrel costs 50 cents per gallon, and sealed 3 and 5 gallon cans retail at 60 cents per gallon. Only one filling is required all Winter, and it is stated that the liquid will not harm the hose or corrode the metal parts of the cooling system.

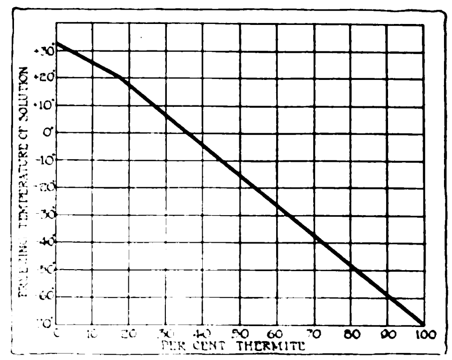

Fig. 10—Curve showing relation between freezing point and amount of water added to Thermite

Vol. XXXI New York—Thursday, November 19, 1914—Chicago No. 21

The Automobile

Fashion Hints on Winter Wear

Part I—In Which Are Reviewed the Modish and Warmth-Giving Garments for Men

Part II, to Appear in an Early Issue, Will Depict Ladies' Automobile Apparel

One of the most comfortable garments provided to meet the needs of men who like to hear the rhythmical hum of a good car over a frozen road and to feel the crisp, cold air sting their cheeks as they spin along. This is an imported double-breasted coat which was manufactured in London. It is warmly lined with sheep's wool and has three large chamois-lined pockets. The bottom is re-inforced with strongly stitched leather and the eight buttons enable the wearer to button it closely about him. A. J. Picard & Co., $42.50. The wool cap shown is of the Rodel type and sells for $2. It is made of soft, warm wool and is very flexible.

NOW that the autumn season is over and the tang of winter is in the crisp sunlit air of the afternoon and the chill of the Arctic regions lurks in the twilight shadows, we find our fall automobile clothes beginning to show a surprising lack of warmth and comfort. So we who are fond of the Big Outdoors and the motor's cold weather hum let our thoughts drift toward supplying our wardrobes with an adequate and suitable line of winter garments for use in the car.

Of course, most men hold style in comparative scorn, holding comfort, durability and other common-sense features in infinitely higher esteem, but, just the same, when a man invests his more or less hard-earned money in an outfit for winter automobiling he wants it to show taste and at least a few becoming qualities. With this idea in mind, experienced representatives of The Automobile have gone over the stocks of a number of the most up-to-date automobile clothing supply houses in New York City and have selected the most comfortable, stylish and sensible garments for illustration and description. The men's coats, caps, mufflers, boots, gloves, etc., are taken up in this issue and the attractive apparel designed for the ladies who delight in winter motoring will be presented in an early issue.

A glance over the styles offered for gentlemen's wear suffices to reveal the same underlying ideas of design which were apparent in the spring modes for the motorist. That is, the designers realize that clothes for the automobilist must be cut differently from the ordinary garments of similar type and that they must be at once conventional and stylish in appearance and also comfortable and adapted to special needs. But see them for yourself.

At the left is a gentleman's broadcloth coat with Persian lamb collar which may be buttoned close around the face if desired. The coat illustrated has muskrat lining but this style also comes in marmot, coney and Jap mink. With Skinner satin yoke lining this coat sells for $45 to $275. The same garment is shown below. The cap in that view is electric seal and sells for $5 to $18. Auto Supply Co.

Above is depicted an Angora wool vest which is warm and comfortable for wear in the car and at the same time offers some striking combinations in colors and patterns. The hues offered are of all shades. Auto Supply Co., $6.50 to $9.50

Combination reversible cap made of army cloth and provided with mackintosh hood which may be used either as an ordinary cap or as illustrated above. The hood folds inside. Auto Supply Co., $3.50.

Mackintosh automobile shirt for gentleman's wear with band collar and cuffs. A vest patch pocket is provided and vent holes at the sleeves. The shirt is offered in either black or tan. Auto Supply Co., $20 to $25.

Above at the left—Gentleman's leather boot lined with the softest fleece to insure warmth. Smith-Haines, $12.

In the center — Fleece-lined leather boots. They do not open like the type shown at the left. Smith-Haines, $9.

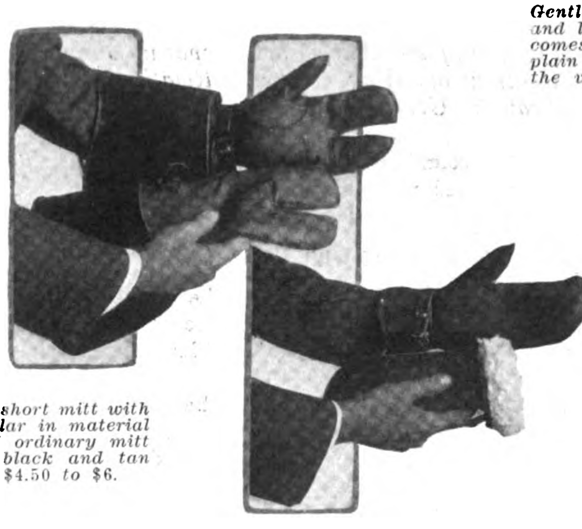
At the right—Men's four-buckle arctics made with cloth uppers and fleece linings. Lowe Motor Supplies Co., $4 to $6.

Below is depicted the single-breasted Jumbo sweater cut in Norfolk style with the usual belt and two lower pockets. The roll collar may be turned up to keep the face and neck warm. Smith-Haines, $8. The wool gloves shown are $2.25 and the Rodel cap sells at the same price.

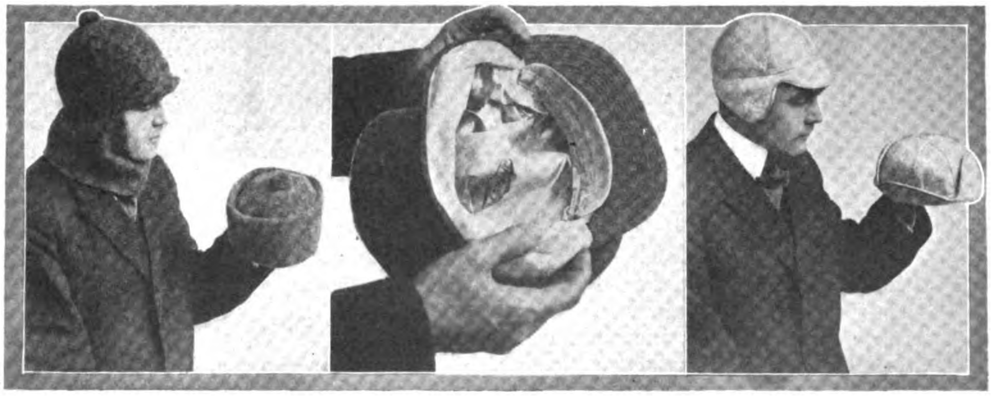
Scotch plaid wool mackinaw in double-breasted form, with belt and three buttons. The mackinaw comes in all color combinations and plain shades and in 36 to 44-inch sizes. Wrist bands are attached. Lowe Motor Supplies Co., $10 to $12. Wool gloves, in gray, navy and black, at $0.50 to $1. Rodel cap, $1 and $2.

Gentleman's automobile coat with set-in sleeves and large patch pockets. This modish garment comes in all combinations of tartan checks and plain colors and a touch of elegance is given by the velvet piping on the sleeves. Auto Supply Co., $32.50 to $47.50.

To the upper right is shown the "Lobster" gauntlet, which gives the warmth of a mitt with the freedom of movement of a glove. It is lined with fleece and sheep's wool and comes in either black or tan leather. Auto Supply Co., $5 to $6.50.



At lower right is illustrated a short mitt with sheep's wool lining very similar in material to the "Lobster" type but of ordinary mitt shape. It is made in both black and tan leather. Auto Supply Co., $4.50 to $6.



Rodel cap in two forms, as worn it is pulled down for protecting cheeks, ears and neck. At right, folded for ordinary use. These caps are of finest wool and come in all colors. Many positions. Lowe Motor Supplies Co., $2.

Gentleman's driving cap with ear flaps. It is chamois lined and is provided with a chamois band for gripping the head, thus preventing the cap from blowing off. It comes in all sizes and colors. Auto Supply Co., $2.50.

Small racing cap of strongly stitched felt. It may be worn in several positions as illustrated. Note the tape binding at the edges to reinforce the material against wear. This cap comes in all sizes. Smith-Haines, $2.50.

Men's great ulster, made to withstand the most icy blasts of winter and to be suitable for all sorts of wear. The garment comes in frizes, chinchillas and worsteds. It is provided with two large patch pockets and is strongly made throughout. Auto Supply Co., $35 to $57.50.

Above is illustrated the Hylo sweater, which may be used either with or without the collar which folds out of sight. It is double-knitted wool and comes in Oxford gray, brown and blue with pearl buttons. A. J. Picard & Co., $8.

At the left are the Night-and-Day goggles, the upper third of the lenses being of amber glass so that lowering the head gives protection against glaring headlights. Leather mounting trimmed with chenille and gold-filled bows are used. A. J. Picard & Co., $3.75.

At the right is shown the Auto-Glas, which, while primarily a gentleman's glass, may also be used by the fairer motorists. It is sold with lenses of smoked, amber or plain glass with gold-filled bows and mountings. Auto Supply Co., $6.

Below is depicted an imported Angora coat sweater which is said to be unusually warm and comfortable for cold weather driving. It comes in all colors. Auto Supply Co., $5. The English cap shown comes in all colors and sells at $1 to $2.50.

Hupmobile Man Sees Fall of Antwerp

Manager of Hamburg Parts Depot in Dangerous Situation on Way to Visit Relatives—Breaks Through German Lines on Third Attempt

M. GASTON MARBAIX, manager of the Hupmobile Hamburg Parts Depot, has arrived in Detroit from Belgium, where he witnessed the fall of Antwerp.

"On the way to see relatives in Belgium," said Mr. Marbaix, "I had to take a round-about route. I first went to London, then to Ostend and from that place to Antwerp. When I reached London my German passports availed me nothing, and it was only through the assistance of Mr. Whiting, Hupmobile dealer there, that I was saved many difficulties.

Refugees in Flight

"At Antwerp I had my first view of the war. It was just before the fall of the city, and with the Germans only a few miles from the town, the inhabitants were in the utmost confusion. Refugees fleeing from destroyed or threatened districts, at first in scattered, straggling groups, and then in solid columns, passed through the town unendingly. Mainly they were afoot, though now and then a farmer's wagon would bulk above the weaving ranks, and it would be loaded with bedding and furniture and packed to overflowing with old women and babies. The majority of fleeing people were peasants, and as more than half of them wore wooden shoes the sound of their feet on the cobbled roadbed was like a battery of guns in action.

Aids Wounded with Car

"I at last located my brother, who was a volunteer in the medical corps in the army, and accompanied him on his rounds among the Belgian lines. We motored from the town to the most outward ring of forts, which was then bearing the brunt of the attack, and picked up whatever wounded we could find, bringing them back to the hospitals, which were already overflowing. The ghastly sights that I witnessed among the dead and wounded have since been the cause of many sleepless nights, for the horrors are unbelievable. Men maimed by shrapnel were literally torn to pieces, and I saw one poor fellow's arm shot away.

Through the Lines

"On the way to Mons I had to pass three times through the German lines. The first two attempts were unsuccessful, and each time I was sent back. At last, however, I hit upon an idea which carried me through.

"I had probably traveled about half the distance between Antwerp and Mons afoot when I stumbled upon a farmer with a load of potatoes who was going to my destination. He was well aware of the presence of the enemy in this vicinity, and he told me that the only way we could safely get through the lines was for me to get at the bottom of his wagon and be buried in the potatoes.

A Dangerous Moment

"The journey took 2 hours over cobblestone roads. We had traveled about 10 miles when I heard a sharp command to halt in a guttural German voice, and I could distinctly hear the conversation which ordered the driver off the wagon as the German soldiers wanted to buy the load of potatoes. I knew the Germans would shoot me on the spot as a spy, and there would be no investigation as to who I was, where I was from, or anything concerning me. I at last made out that the driver was trying to explain that the potatoes were for a German regiment which was some distance beyond, and after showing passports, etc., we were allowed to proceed.

Off for Home

"We finally reached Nimy, and I was very glad to get out and breathe fresh air again. I spent very little time at this place and made all haste to Ostend, where I embarked for London and thence to the United States."

Cars and Trucks on the Firing Line

Fleets of Trucks Needed for Convoys—Use American Machines—Motor Mail to Trenches—German Tire Plant Closed—Design of Armored Cars

By W. F. Bradley
Special Representative of THE AUTOMOBILE *with the Allied Armies in France*

PARIS, Oct. 28—In addition to the purchase of 2- and 3-ton trucks, for service in the French and Russian armies, the authorities are open to take delivery of touring car chassis to be fitted with light van bodies for quick transport work. The reason for turning to America for this class of vehicle is the inability of the French manufacturers to deliver fleets of cars. The French Government has requisitioned from private users all the automobiles it is likely to need for months ahead, and is keeping these machines in reserve at various military garages in Paris and elsewhere.

The cars taken from private service are a diversified set only suitable for individual service such as carrying officers. It is impossible to put machines of different make, widely different horsepower and weight, into convoy formation. Experience has shown that cars worked under these conditions are mutually destructive.

This makes it necessary to apply to manufacturers for fleets of not fewer than twenty uniform cars; but as the French passenger car manufacturers have not kept together sufficient staffs to fulfil such orders, it has been necessary to turn to America. Complete touring cars are not required. Chassis only are being bought, the horsepower being 15 to 20, European rating.

It is intended to fit these machines with very simple van bodies, but in all probability this work will be done in Europe. Detachable wheels, whether wood or metal, are looked upon with approval. Tires should be European millimeter size, for very few American size tires are made in Europe.

Spares Needed

All necessary tools and spares must be supplied with the cars. The necessary spares for active service are as follows: set of spark plugs, set of bolts, nuts and washers, set of gaskets, carbureter float, carbureter jet, magneto parts, one set of brake shoes, one main and one connecting rod bearing, one of each type of ball bearing used on the car, one of each type of screw-down greaser, one valve complete with cup and pin, one set of piston rings, a set of steering gear levers, one fan belt, a clutch leather or set of disks in case of a metallic clutch, a piece of each type of

A fleet of Kisselkar trucks recently shipped to Europe for use by the armies of the warring nations

rubber tube for water circulation. With this list of parts the car is prepared for almost any emergency, yet the weight is not sufficient to seriously interfere with the speed or load capacity of the machine.

These parts are those which must be furnished with every truck supplied to the French army. Where a number of vehicles is taken over, as for instance in the case of the 1,100 Paris motorbuses, all of one type, the spare parts are reduced so that the complete set is spread over each group of ten or twelve cars, these ten or twelve working together as a convoy. This plan will be followed, doubtless, for the touring car purchases, so as to reduce the weight of the spares to be carried by the individual cars. At the same time there will be found everything necessary for replacements in each group.

Mail Motors at Trenches

Automobiles have solved the difficult problem of getting mail to the troops in the firing line. The operation is complicated. For military and administrative reasons all letters have first to be sent to the regimental depot, which may be hundreds of miles from the firing line and from which it is known the men were sent away 3 months ago. At the depot the letters are sorted and dispatched to the general headquarters, which is some distance back of the firing line. At this point the automobile service steps in. Most of the Paris postal vans—two-cylinder Delahayes—have been sent to the front and make journeys out from general headquarters to the different batallions. A cyclist accompanies each van, his machine being carried on the top of the automobile, and assists in the final distribution of the letters. Where the men are scattered over a small area it is possible for the cyclist to deliver more expeditiously than the automobile, the car meanwhile making a longer trip and picking up the bicycle on the return.

Parcel Post to Trenches

In addition to the official service, the Automobile Club of France has been carrying out a special parcel post service for the benefit of men at the front. The club has undertaken to deliver to the men parcels of clothing, tobacco and other comforts, prepared by relatives and friends. At first these were delivered direct to the men to whom they were addressed, but of late, owing to the scattered nature of the operations, it has only been possible to take out anonymous parcels, which are handed over to officers at the front and distributed by them to the men most in need of the goods. The club is maintaining a constant service of automobiles throughout the whole of the territory occupied by the French army.

German Tire Factory Closed by Order of France

PARIS, Oct. 28—By order of the French Government, the Continental Tire Co.'s Paris and suburban establishments have been closed and probably will not be allowed to open again under any conditions. The Continental Co. is a German firm with headquarters at Hanover. A French branch was founded as a "société anonyme," under the French laws, some 8 or 9 years ago, but all the stockholders, with one exception, were German. On the outbreak of war the offices and sales department in Paris were closed and practically all the directors of the company left immediately for Germany. The firm's important factory at Clichy, in the suburbs of Paris, was allowed to remain open, under the control of Maurice Echalié, the only French member of the firm. It is probable that the whole of the tires manufactured since August 1 were purchased by the French army. In addition, the whole of the stock of the company was requisitioned.

Factory Used for Spying

Recent revelations of German firms spying and assisting the military authorities of their country with a view to an invasion of France have so aroused the public that it has become necessary to order the closing of German establishments. It is in consequence of this order that the Continental company has been shut down. For at least 2 years there has been an attempt on the part of the leading French tire firm to prove that the Continental establishment was merely a subterfuge to cover an extensive system of spying, particularly with regard to military aviation and automobile matters. Until the outbreak of the war, however, the public refused to look upon this campaign as anything more important than an adroit publicity scheme.

Close American Depots

On account of the war it has been decided to close the Paris branch of the Hudson Motor Car Co. About a year ago it was decided to make a bid for Continental trade. F. O. Bezner, one of the vice-presidents of the company, took charge of the campaign, and had made plans for participation in all the automobile shows this fall. John Olt, general sales manager, sailed for America early in the war. As the fighting seems likely to be of long duration, Mr. Bezner has decided to wind up the French branch.

The Pierce-Arrow Motor Car Co. has withdrawn from the French market. The company has maintained a Paris depot for several years, but on the recent expiration of their contract they decided not to renew. They are now unrepresented on the continent, although a spare parts depot has been established in London.

R. N. Goode, general manager of the Paris branch of the Packard Motor Car Co., is leaving Paris this week for the Detroit factory. It is understood that Mr. Goode has in his pocket a big order for Packard touring car chassis and trucks to be supplied to the French or Russian armies, or probably to both.

Close Terrot Co.

Declared to be backed by German capital, the Terrot Automobile Co., at Dijon, has been closed by order of the Government, an official receiver being put in charge. This firm produced bicycles, motorcycles, and recently placed on the market a popular type of light car. The shutting down of German firms is proceeding apace, but the number of automobile and kindred establishments affected in this way is very small.

News of Race Drivers

Robert F. L. Crossman, lieutenant in the British navy, is officially reported to have been captured during the fighting around Antwerp and sent as a prisoner into Germany. Crossman is a well-known English race driver who will be remembered by Americans as mechanician to Albert Guyot on the Sunbeam car in the 1913 Indianapolis 500-mile race. Before becoming interested in automobile racing Crossman held the rank of lieutenant in the British navy.

Albert Guyot, who drove in the last two Indianapolis races, has been treated in the military hospital for dysentery. As the attack was not very severe, Guyot was not sent back to the military base, but was treated in the field hospital somewhere on the eastern frontier.

Robert Laly, who rode with René Thomas on the winning Delage at Indianapolis this year, has not been heard of since the outbreak of the war. Laly, having but recently completed his military service, was one of the first to be called up and was sent direct to the eastern frontier, where the most bitter fighting took place.

After serving as an artilleryman in a fort at Belfort, Jules Goux has, on his own request, been transferred to the automobile section. Recent reports from the front indicate that the following automobilists on active service are still in good health: Georges Boillot, Charles Faroux, Victor Rigal, Jean Chassagne, Louis Wagner, G. Caillois, Arthur Duray, Rougier, Champoiseau, who for a time was detailed for army Red Cross service with Mr. Bacon, former U. S. Ambassador; Gabriel, and René de Knyff, president of the Sporting Committee of the A. C. F.

Henry Mathyss, mechanician for Arthur Duray on the little Peugeot which finished second at Indianapolis last May, has volunteered for automobile service with the French army and has been accepted. Both Duray and his mechanician are of Belgian nationality and in consequence not under military obligations.

New Paris Buses

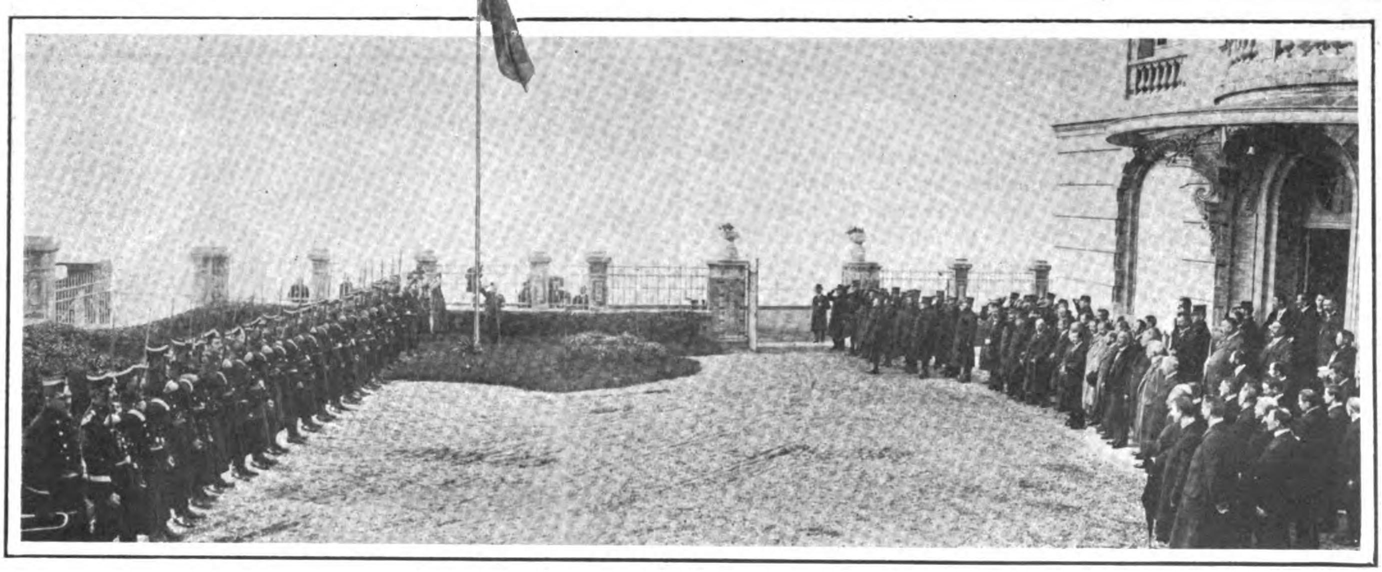
It being anticipated that the 1,100 Paris motorbuses now with the French armies will never again see service on the streets of the capital, arrangements have been made for a new fleet to be prepared. The new motorbuses will be single deckers, with motor under the driver's feet. The width and height are to be increased, while the windows on one side will be fixed. It has been found possible to decrease the weight 1,500 pounds. The acetylene lighting set has been replaced by electricity.

Since the outbreak of the war there has been no bus service whatever in Paris, the whole of the vehicles having gone on their war mission within 24 hours of the declaration of mobilization. The buses have given remarkably good service, mechanical breakdowns being exceedingly rare, whereas private trucks have had to be abandoned by the roadside. There does not appear to be a single case of a bus having gone out of business by reason of mechanical weakness. Naturally some have been lost by reason of shell fire and road accidents, but these had no connection with mechanical breakdowns.

After practically 3 months' hard service, during which they have never been under cover, it has been decided to send the motorbuses back to their base in small batches for a mechanical inspection and the fitting of new tires.

250 Motors Feed 750,000

As meat wagons, in which service most of the Paris buses are employed, it is possible with 250 buses to feed daily 750,000 men. In order to assure absolute reliability, however, 500 buses are made use of for this number of men. Each bus can carry daily about 4,000 pounds of fresh meat to the firing line. This quantity of meat is sufficient for a regiment comprising three battalions of 1,000 men. The daily ration of fresh meat is about 1 1-3 pounds per man. Twelve buses are capable of supplying an entire army corps with fresh meat, but in order to allow for unforeseen circumstances this number is doubled.



A daily ceremony at the Belgian Ministry of War in Havre, France. As the Belgian flag mounts to the top of the pole, the Belgian Guards and officers of the general staff salute it and swear to fight till death in defense of their country

Armored Cars the Allied Armies' Greatest Requisites

PARIS, Oct. 28—Automobiles fitted with machine guns and armor plating for touring cars have proved to be the two greatest requisites of the Allies in this war. It is now evident that the German military authorities had realized the immense importance of possessing guns with greater mobility than can be obtained from the use of horses. On the outbreak of war they had large numbers of cars, each one carrying a rapid firing gun, with complete protection by means of armor plating, by means of which they were able to make rapid invasions into the enemy's country and to inflict enormous damage. There is no doubt that the value of these guns was enhanced 100 per cent. by reason of their extreme mobility. Officers of the Allied forces have declared that again and again their infantry have got within striking distance of the German automobile guns, but have been unable to capture them.

Four-Wheel-Drive in Demand

Although the French had studied this problem of armored automobiles, and had produced a most efficient type, only a very small number were ready to go into active service on the outbreak of war. More attention had been paid to the haulage of heavy guns—about 6-inch bore—by means of four-wheel-drive gasoline tractors, in place of horses. These have given satisfactory service.

Chassis Haul Guns

In England little had been done in the matter of armored cars. Some satisfactory experiments were carried out early this year with hauling guns long distances by means of powerful Sheffield-Simplex chassis. The significance of these experiments is shown at the present time by the appointment of one of the most important financial backers of this company as head of the mechanical transport service of the British army on the Continent. Under the Sheffield-Simplex scheme the guns were merely towed behind ordinary chassis. The experiments proved that guns could be hauled in this way, over medium roads, at an average speed of 30 miles an hour.

With wonderful rapidity the conditions pertaining at the outbreak of the war have been changed so that the Allies doubtless have now more armored automobiles than are possessed by Germany. No figures are available, but it may be stated that hundreds of automobiles have been fitted with guns and encased in plating. One firm alone delivered 200 chassis to the arsenal to be fitted up in this way. So strong is the faith in the automobile gun that certain officers have had guns sent out to them from England, apart from the official channels, and have had them fitted to armored cars. The English and French naval brigades have a particularly strong equipment of these machines.

Design of Armored Car

There is no uniformity in the design of the new military weapon. Two-ton trucks, as well as powerful touring cars on pneumatic tires, are made use of. Various types of guns are fitted. The point is that any gun is rendered immeasurably more useful by being mounted on an automobile. The nature of the armor plating varies from a complete housing, covering the hood, wheels, driver, and forming a turret for the gun, to ordinary trucks with a steel plate along each side, over the top of which the gun is fired.

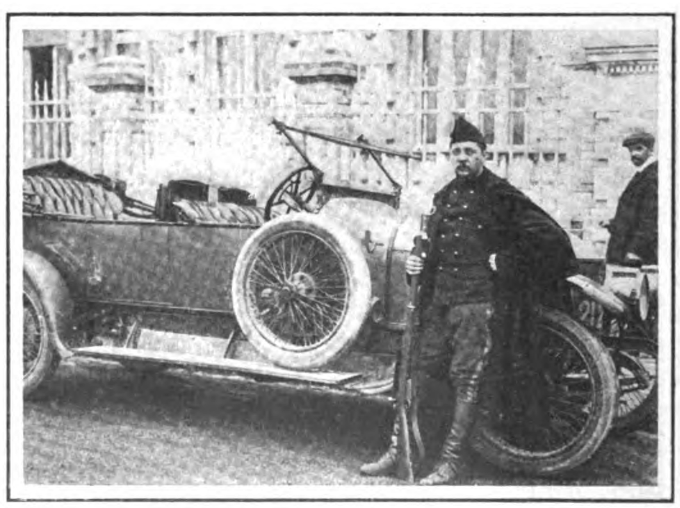
The cooling problem is overcome by hinged doors in front of the radiator, or by steel louvers capable of being operated from the driver's seat. On the lighter type of machine the tires are protected by a front and rear extension of the fenders, special steel being used, and the sides being left unguarded.

The more elaborate of these automobiles have a set of struts, or jacks, raising the entire chassis from the ground and giving it a greater amount of rigidity than it can possess when on its wheels with springs interposed. The rapid raising of the chassis, so as to transform it into a rigid platform, is one of the features and secrets of the vehicle.

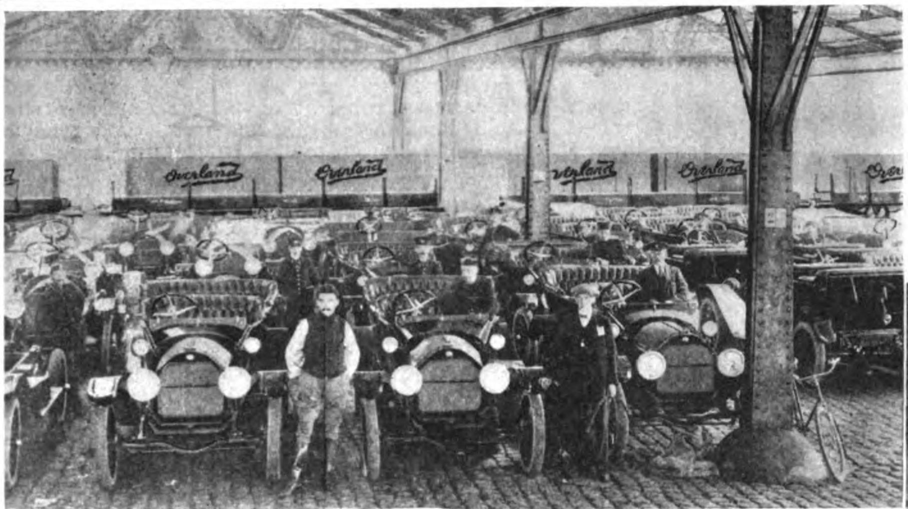
Protect Radiator and Driver

All touring cars in use at the front should have a certain amount of protection, particularly for the driver and for the radiator. Many of the cars which were sent out unprotected have since been transformed in order to give this additional security. This protection need not be of an elaborate nature, indeed it must be as simple as possible in order not to rob the car of any of its usefulness as a rapid means of conveyance. The object is to make the car proof against rifle bullets and splinters of shrapnel. It is obvious that no automobile can be made proof against shell fire and remain a fast vehicle.

The most important feature is the protection of the driver. This has been done in many cases by mounting a chrome nickel steel semi-circular shaped plate on each side of the body, level with the men in front, and slightly above their heads. This gives sufficient protection against side attacks, which are the most common, and is in many cases considered sufficient. In every case the object of an attacking party

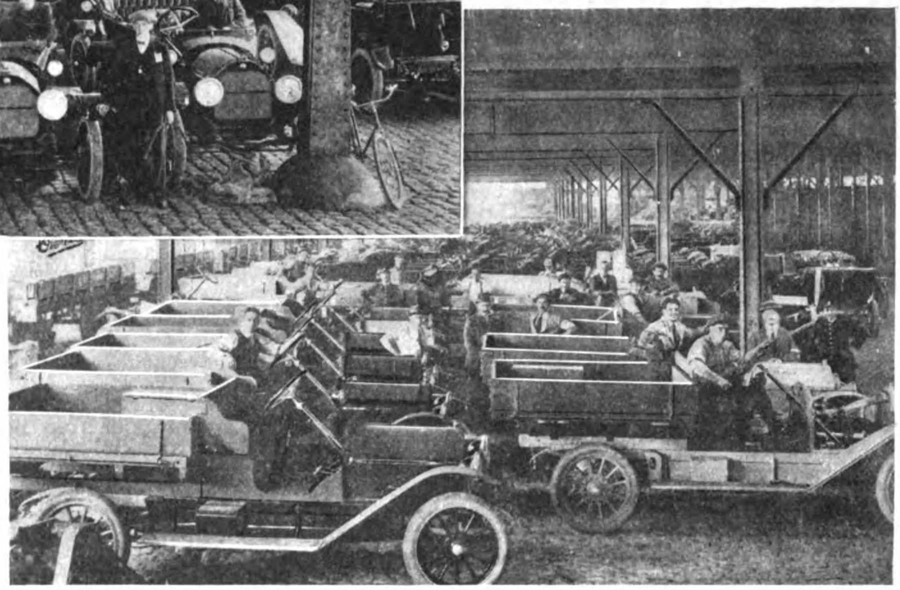


A soldier of the Belgian Guards on duty before the official car of the Belgian Government in front of the provisional headquarters at Havre



At the left are shown some of the 300 Overlands sold to the Belgian Government, before the soldiers had started the work of changing the bodies

Below is a view of the same cars with the roughly constructed bodies used for military purposes. The entire order was filled and delivered with bodies changed in 6 days



is to bring down the driver. If he can be killed or wounded it becomes a comparatively easy matter to dispose of the officers he may be driving.

On more elaborate types the armor plating is continued along the entire side of the car, flush with the heads of the occupants when they are seated low, a protective plate is put along each side of the hood, and a wind cutter of special steel is placed in front of the radiator.

There is some necessity, too, for protection of the gasoline tank, if at the rear, for cases have arisen in which this has been punctured by bits of shrapnel. A gasoline tank under the dash hardly needs any special protection. The tendency is to put as little armor plating on touring cars as possible. If the driver is tolerably safe the other occupants may take the risk.

Reverse Driving

It has been proved that on touring cars serving for reconnoitering purposes a highly geared reverse and a duplicate steering set, allowing the car to be driven stern first, are most valuable adjuncts. On this type of car there are two reverses, a low and a high, and a duplicate set of spark and throttle controls on the emergency reverse steering wheel. For raiding purposes this type of vehicle is invaluable. It can run into positions which the driver of an ordinary car would consider extremely dangerous and can get away again with ease. The amazement of the attacked troops is great on finding that the attacking car can move astern as fast as it has come ahead.

300 Overlands for Belgium

A big squadron of 300 Overland cars is one of the factors in the remarkable resistance being made by the intrepid Belgians against the overwhelming forces of the Kaiser.

The Overlands were used continuously during the retreat from the city.

The cars were purchased shortly after the actual opening of hostilities from the stock of the Willys-Overland, Ltd., London distributor, by a commission of army motor experts headed by Colonel Jammott, chief engineer of the Belgian artillery.

A number of motor cars and light trucks figured in a series of exhaustive tests held to determine the ones best fitted for rigorous service in the field. In the course of the trials an Overland car, equipped with a special military body prepared for the purpose, traversed the long Hampstead Hill in this city, on high speed, carrying a load of petrol approximating 1,900 pounds. The resultant sale was the largest individual order for cars ever placed with a single firm in the history of the automobile industry in England.

Immediately after the tests the Belgians ordered 200 Overlands. Although this was the entire number of cars they had been authorized to purchase for their Government, they found the machines so satisfactory for their purpose that a second order for 100 additional cars of the same make followed shortly after the officers had made their report to headquarters.

Bodies Made in 6 Hours

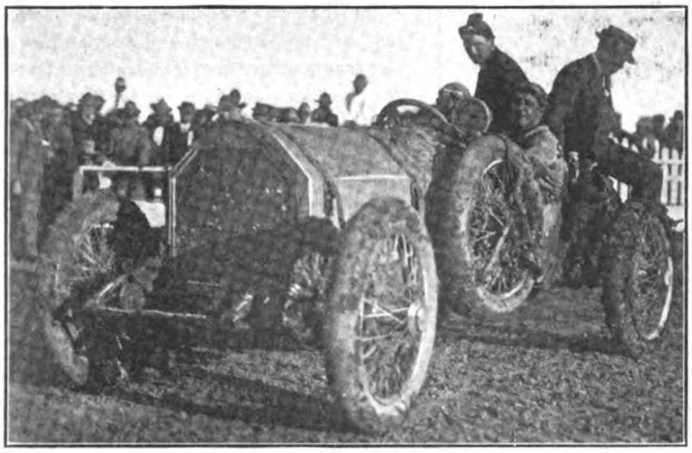
On the same day that the first order was received a prominent London body manufacturer started the construction of bodies for military use, using the specifications laid down by the Belgian engineers. As time was urgent, an extra force of men was kept in the factory night and day until the entire allotment had been finished. Under this pressure the English workmen required but 6 hours to turn out a complete body.

Together with the cars the bodies were shipped to Antwerp aboard a channel boat chartered especially for the purpose. Accompanying them were ten expert mechanicians from the London establishment and a score of men from the body shop.

The touring car bodies were discarded and the hastily constructed military bodies attached to the chassis in their place. In a remarkably short space of time the entire task was completed and the 300 cars were ready.

300 Cars Ready in 6 Days

Within 6 days after the first order was placed the 300 cars, altered and adapted to military service, had been officially turned over to the Belgian army, together with a proper assortment of duplicate parts. The mechanics remained in Belgium for several days after the cars had been placed in service to assist in training the soldiers in driving and caring for the cars.



Barney Oldfield's Stutz as it won the Los Angeles-Phoenix race

Eight Finish in Big Desert Race

Twelve Cars Eliminated by Gruelling Grind—Oldfield, in Stutz, Wins

PHOENIX, ARIZ., Nov. 11—Eclipsing all past revivals of the great desert classic, the seventh annual Los Angeles to Phoenix road race passed into history with Barney Oldfield the winner.

Twenty cars started from Los Angeles Monday morning, November 9 at daybreak. One by one they were conquered by the desert and mountain roads until there were only eight in the running and one arrived at the finish line after the control had been officially closed.

For 3 days, Oldfield in the Stutz racer which was the first American car to finish in the International Sweepstakes at Indianapolis last May, led the field. At Needles, the first night control, Barney had the lead by a scant 5 minutes and 55 seconds. At Prescott, the second night out, the Stutz was 48 minutes ahead and at the finish of the 696-mile battle with the elements, the veteran took first honors over Louis Nikrent in a Paige, by just 35 minutes.

With the first money, Bullock's, Gondolfa's and the Arizona Republican trophies, Oldfield wins the diamond trophy bearing the inscription, "The Master Driver of the World."

By winning the "Cactus Derby" in a tuned racer, Oldfield has wrecked sacred Western racing traditions. Never before has a racing car made good in the Phoenix road race.

The Paige cars which won second and third places in the great race also created a sensation.

The little Chevrolet also made a great showing and the 1911 Cadillac, piloted to fifth place by the veteran Bill Bramlett, was a wonder of the race.

The battery of racers that lined up for the start November 9 included everything from the Ford and Metz to the Simplex and De Dietrich.

At midnight rain began falling. By the time that the first car was to be sent away, at 5:30, the course for the first 61 miles to San Bernardino was positively dangerous. The drivers who had them put on chains.

Ford Led to San Bernardino

The cars were sent away from the line at 2-minute intervals. As far as San Bernardino, they held very close together, several checking in at that point only seconds apart. Earl Schnack of Escondido, Cal., in the little Ford, led the race to San Bernardino by 3 minutes, and was still in the counting, 100 miles out; but the little machine met disaster before the first day's run was over.

The first car out in the race was the Alco driven by Bill Taylor. This car took third honors in the American Grand Prix at Santa Monica last spring and was looked upon as a dangerous contender until Taylor skidded into a telegraph pole, a few miles from the start, and was hopelessly out of the running.

Many cars had trouble in the narrow Cajon Pass. Several skidded over the edge of the road, although with the exception of the Alco and the Metz No. 11, all cars reached Victorville, 102 miles out on the desert.

Durant in the Chevrolet No. 2 and Barney in the Stutz, checked in and out of Barstow not a minute apart, and from that point on across the desert to Needles one of the most spectacular road races ever witnessed took place.

Oldfield in the Lead

Oldfield led. Sometimes the Chevrolet would almost overtake the Stutz. The third car, the Simplex with Olin Davis at the wheel, would come out from behind a jagged butte and all but pass the leaders, then would settle back and hold its own against the rest of the field. At Needles, the Chevrolet and Stutz were so close together that when Oldfield ran over the line he had to back back till the Chevrolet was checked in. While Oldfield had a five minute lead in time, he was second in position at the end of the first day's run by just eight seconds.

The Paige No. 1 finished third followed four and a half minutes later by Davis in the Simplex 4 minutes ahead of Louis Chevrolet in the Chevrolet No. 20 which he had pushed to the limit for the entire 303 miles.

The de Dietrich, KisselKar, Thomas and Ford all went out on the run between Barstow and Needles. This left but fourteen cars in the race and when the start was made the next morning, the Metz No. 14 went out.

Louis Nikrent in the Paige No. 8 finished the first leg of the course 1 minute behind the Chevrolet, but he had stopped outside of the control to fill up, tighten a few bolts and make ready for the start in the morning.

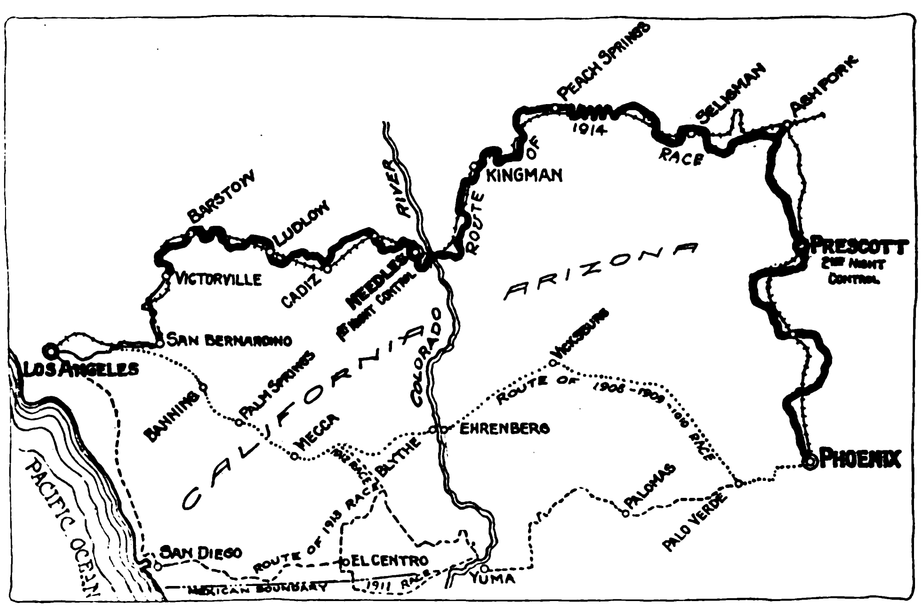
Rain was falling at the time of the start from Needles. The cars skidded from side to side over the muddy mountain roads to the Santa Fe bridge which crosses the Colorado River 17 miles below Needles.

Crossing the bridge, Durant lost 6 minutes making a tire change. Oldfield had trouble getting water in his radiator, having screwed the cap on too tight the night before and he also lost time after the start, giving both Beaudet and Davis several minutes' start.

Nikrent, Carlson and Chevrolet all crossed the bridge together and raced across the roads to Kingman.

The speed of the Simplex came in for a show on the road to Kingman after the dust had been laid and Davis led into the 374 mile control with 8 minutes on Oldfield.

At Kingman Oldfield discarded the wheel with the flat tire which he had driven 11 miles in a losing speed brush with



Map of course followed by contestants in the seventh annual Los Angeles-Phoenix race

Nikrent, and lost more time. Durant also suffered in a duel with the other Paige.

As Beaudet bowled along with Durant chasing him at about 60 miles an hour the Chevrolet struck a rock and the right rear wheel was badly damaged. However, Durant drove into the control only 10 seconds behind Beaudet.

Leaving the Kingman control in second place with several minutes over both Barney and Durant, Beaudet skidded to the side against a bank and sprung a leak in his radiator.

Back to Kingman he drove and while he was patching the hole, Barney and Durant pulled out together and Nikrent went into second place, 5 minutes behind the Simplex.

Louis Chevrolet, Bill Carlson and Du Bois in the Cole, left Kingman close together.

At Hackberry, Carlson broke a wheel on his Maxwell. Teddy Tetzlaff in the Maxwell Press Car overtook him and taking the wheel into Seligman the damage was repaired but when the driver returned to his car at Hackberry, he found it stripped of carbureter, magneto, all tires and the two extra wheels which also carried two extra tires. That ended the game for the Maxwell.

Regular Storm at Seligman

The rain increased until there was a real storm at Seligman, Davis in the Simplex cut a piece of the tread off his left rear tire and stopping to change wheels and buy rubber coats for himself and Redford his mechanic, Barney went through the town and into first place, followed by Nikrent who had also stopped at Seligman to fill up for the hard run over the mountains to Prescott.

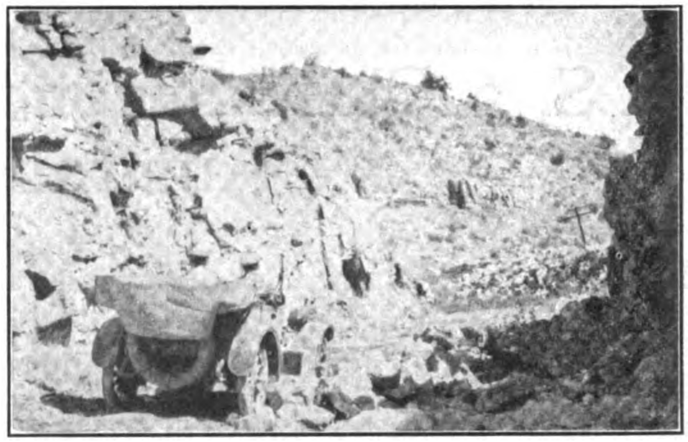
Anxious to assist Chevrolet one of the natives picked up the wrong can and poured 5 gallons of water into the gas tank of the Chevrolet No. 2. This was not discovered, however, and a few miles out, the car refused to move. Marooned in the rain on the desert, Louis was finally overtaken by the crippled Chevrolet No. 2. Taking a wheel off of the waterlogged car, No. 2 was soon in running condition.

Oldfield was first at Prescott, the second night control, with a lead of 48 minutes and 5 seconds over the Simplex. Nikrent held third place, 8 minutes behind Davis.

Eleven Cars Reach Prescott

The eleven cars which reached the 558 mile post at Prescott were all in good condition with the exception of Beaudet's Paige and it was still anybody's race. Another leaky radiator robbed Beaudet of enough time to put him in second place.

At New River, 15 miles out of Phoenix, Barney stalled his motor in the middle of the stream and had to hitch ropes on the car and have spectators and a team assist him through the wet sand. Fifteen minutes were lost at this point and



Rough going through Rocky Canyon on the Los Angeles-Phoenix race course

Barney felt that he had lost the race. Nikrent had passed him and Bramlett in the Cadillac No. 20 had pulled through the stream several minutes ahead of him.

Oldfield's Winning Spurt

Heedless of danger, Oldfield slid from side to side on the road in a mad drive to the tape, hoping that he would win at least second place, but believing that he had lost to Nikrent.

As he came down the road, the car and crew looked like an adobe house on wheels. The cigar in his face had turned to a clay clod and the mask on his face had holes where mouth and nose were hidden.

The first to finish was Nikrent and as the crowd waited for the next car seconds were counted, as each minute counted in the fight for the "Master Driver's" title.

Bramlett in the old Cadillac was the second man to finish. A short distance out of Prescott the Cadillac went over a 12-foot embankment. The rains had made the mountain road so slippery that Bramlett's brakes would not hold. A crowd of spectators assisted the driver and mechanic to get the car back on the road, but the steering arm was so bent that Bramlett could hardly turn to the left and later the arm broke off.

Without a word, Bramlett tore two rails from a fence and giving one to his mechanic, the damage was repaired. Lashing a rail to either side of the front axle, the driver and mechanic steered the last 15 miles to the finish, traveling at about 30 miles an hour, by leaning over the side and rubbing the rail on either side of the tires.

The Simplex was eliminated from the running when a few miles out of Prescott. In second place with an even break for first honors, Davis broke a torsion spring and drive chain, skidding into a bank and retiring from the lists.

Durant and Chevrolet in the Chevrolet No. 2 were making fast time between Wickenburg and Hot Springs Junction when they lost a hub. Taking a wrench, they improvised a hub by tightening and lashing it down with tape. With this makeshift they were only able to make about 20 miles an hour, but they fought to the finish and beat Bramlett out of fourth place by a margin of 34 minutes.

The Buick No. 15 ran in hard luck throughout the race. Just out of Los Angeles the Ellis brothers went into the ditch. They got back into the race and continued on to Daggett where they again went in the ditch. Never able to regain the lost time, the boys finished 2 hours out.

Not willing to give up the race, the Metz No. 9 made the run into Prescott and started out on the last lap of the course with Wing determined to reach Phoenix, which he did at midnight.

The Kincaid special followed along in the wake of Barney in good time until about 60 miles out of Phoenix. A twisted axle stopped its career.

The Cole, entered and driven by Bu Bous of Phoenix, the only Phoenix car in the race, fought to the finish.

The Stutz No. 17 did not get through as well as Barney's No. 5, but the car reached Phoenix after a hard race.

Oldfield did not make the time that Olin Davis in the winning Locomobile did last year; but the course was harder on account of the rains. Davis' time for the run over the 564 mile course by way of San Diego and the Imperial Valley was 31 miles an hour. For the first 300 miles, Oldfield averaged 38.4 miles an hour. The second day he fell back to a 31.5 average and the last lap was below 30 miles.

Time of Cars Finishing in Los Angeles-Phoenix Race

Car	Driver	Los Angeles-Needles	Needles-Prescott	Prescott-Phoenix	Los Angeles-Phoenix	M.P.H
Stutz	Oldfield	8:45	8:18	5:56	23:00	30.2
Paige	Nikrent	9:25	8:35	5:35	23:35	29.4
Paige	Beaudet	9:14	9:58	5:51	25:04	27.7
Chevrolet	Durant	8:51	10:27	6:27	25:46	27.0
Cadillac	Bramlett	10:02	10:38	5:40	26:20	26.2
Buick	Ellis	11:00	10:14	6:44	28:22	24.5
Stutz	Burns	10:17	11:15	8:16	29:48	23.4
Cole	Du Bois	9:44	14:31	7:41	31:56	21.8

Picturesque scenery and Mojave Indians on Los Angeles-Phoenix race course

U. S. a Close Second to Great Britain for Australian Trade

Leads by 1 Per Cent. in Importations of Chassis and Bodies in First 6 Months of 1914—English Imports Worth $455,100 More—European War Depresses All Business in Antipodean Continent

THE European war has made a terrible depression in Australia. From the very day that England declared war, automobile business went flat, and no one had any consideration for anything else except war news.

The country has been in a state of financial nervousness ever since the war started, but it is beginning to show signs of a slight recovery. Just how long the recovery will last it is hard to say at this present moment. What has troubled the country most, has been the disposal of wool, which has stopped, and wheat is being cornered or commandeered by the Government. It is almost impossible to buy any motor trucks, as the military authorities have taken everything. The Government is taking all kinds of steps to prevent monopolies coming in and cornering commodities. As a consequence, the capitalists and speculators are all standing aloof and doing nothing, thus affecting the automobile trade and everything else.

Export Trade Stopped

The stoppage of the export trade has created a natural depression in the factories. This condition is prevailing throughout Australia, but it is not affecting New Zealand so much. The war has come when normal conditions should have prevailed, with the usual run of prosperity, although one or two parts of the Continent have had a rather dry spell.

U. S. Leads by 1 per Cent.

This condition of affairs has affected, particularly, the automobile export business from the United States and the United Kingdom. Both these countries have had a large export trade in automobiles and parts with Australia. In fact, for a number of years it has been a close race between the two for supremacy in that particular trade, the United Kingdom always leading. But in 1914, the United States came to the fore, leading that country by 1 per cent. in the total importations of chassis and bodies and supplying 32 per cent. of the total importation. The value, however, of the English cars was $455,100 more than the American, amounting to $1,491,525; the American, $1,036,425. During the first half of 1913 the United Kingdom led the United States by 5 per cent., or 36 per cent. of the total importation.

During the first 7 months of 1914, 2,587 cars, valued at $2,233,471 were exported to Australia, as compared with 1,873, valued at $1,827,690, for 1913, a gain of 22 per cent.

July Exports Increase

Even the July exports show an increase. Cars numbering 311 and valued at $237,780, were exported, as compared with 277, valued at $240,734, for 1913. These figures would indicate that low-priced cars are gaining a strong foothold there. In speaking about these cars, it may be said that the small European car is most popular in the cities, while in rural sections, the American car is in greater demand.

$8,000,000 in 5 Years

American exports into Australia since 1909 have amounted to more than $8,000,000. This country has shown a most remarkable increase. From the figure of $50,625 in 1908, this value has risen to $1,433,320 or nearly thirty times its magnitude. None of the other countries has made nearly the same progress.

Australia, as an automobile buying territory, has made most astonishing headway in the last 6 years. Agriculture, mining and a variety of industries make that country a territory of considerable buying power. That the automobile industry is getting its share is shown in the importation of $3,996,945 worth of automobile chassis and $703,125 automobile bodies in the first 6 months of this year, a total of $4,700,070.

This country, made up of six states, New South Wales, Victoria, West Australia, South Australia, Queensland and Tasmania, has a population of 4,830,517. Though about one-third the size of South America, American automobile business there in 1914 was thirty times that of South America.

American Bodies Lead

The importation of American bodies has been far ahead of any of the countries, dating as far back as 1911. For 1914, Australia imported nearly $150,000 worth more of American bodies than English. The United Kingdom, however, has always led this country in the number of chassis imported, this year's lead being $98,535. This figure, however, shows that the United States has made a great increase over 1913, the United Kingdom then leading it by $451,110.

Tires Poorly Represented

Though the American importations were second, it may be said that these could have been considerably increased, had attention been paid to tire equipment. A number of the American manufacturers sent their cars over to that country without tires while the European cars were equipped with those guaranteed in Australia. Though some of the American cars were so equipped, no guarantee was given. The reason for this is that only one tire company is represented there. This American company is not nearly as well established as any of the European firms. A number of the European tire companies are building factories to take care of the large trade. The question of tires to the consumer in Australia is a very important one, because of the high import duty.

Greater Increase Than England

The United States showed a better increase in 1914 than England, that is, averaging both the body and chassis imports. The American increase in 1914 over 1913 was 48 1-2 per cent., while that of England was only 6 per cent. The American 1914 increase for body imports over 1913 was 44 per cent., while the chassis import increase amounted to 53 per cent. The English increase in body imports was only 7 per cent., while the chassis imports gained 5 per cent.

New South Wales Buys Most

New South Wales is the largest automobile buying state of Australia. The 1913 imports amounted to $2,581,555 in 1913. These figures include both chassis and bodies, the last named amounting to $358,013. The large demand for bodies is explained as being due to the local demand for low-priced American cars, which are sold for delivery there complete and ready for use. The United States sent chassis valued at $646,038 to that state during 1913. Over $445,000 worth of chassis and over $120,000 in bodies came there from this country during the first 6 months of 1914. England sent over $85,000 worth of bodies and over $470,000 in chassis, leading the United States in the last named. The increase in that state in American cars for the first 6 months in 1914, including both bodies and chassis, was 48 1-2 per cent., while the English increase was 17 1-2 per cent.

Queensland's Increase Best

Queensland, though second to New South Wales in the number of chassis imports, showed the best increase for 1914. This was 37 per cent. New South Wales was next with 33, Tasmania, the smallest state, next with 30; Victoria, 16; West Australia, 10, and South Australia, only .003.

U. S. First in New South Wales

In point of numbers in New South Wales, America takes first place, the Ford registrations totaling 1,043. Overland carries off second place with 434. Third place goes to Europe, the Renault having 345. In the last official report of automobile registrations for this state, the figures show that 79 per cent. of the cars sold have gone into the country districts where farming and pasturage constitute the chief occupations. With this class of population purchasing practically 80 per cent. of the cars, it is not surprising that the low-powered and medium-powered cars should lead.

Canada Leads France

The accompanying statistics show Canada and France well up in the list, the first country leading. France, for 1914, has declined, while Canada has gained almost 70 per cent. over 1913 in chassis imports. Canada also leads France in body imports. France has also declined in body imports.

Information about Australia is constantly coming in, especially through the United States Consulates, established in the various cities. It will be advisable for any manufacturer who desires to export to the Australian continent, to communicate with the Department of Commerce and Labor, Washington, D. C., for information regarding the local conditions.

Plans Trade Tour

BALTIMORE, MD., Nov. 14—The Fidelity Trust Co. has arranged for a 16,130-mile tour around South America, starting from New York City, January 27, and Baltimore, January 29, and lasting 106 days, 52 days of steaming time and 54 in the principal ports of the West Indies and South America. This tour is arranged to enable our bankers, manufacturers, exporters and importers to familiarize themselves with South America.

Automobile and Motor Truck Chassis and Bodies Imported Into Australia in 1913 and First 6 Months of 1914

Russian Imports Gain $184,000

Progress Shown in First 5 Months of 1914

THE accompanying table shows the imports of various kinds of motor vehicles into European Russia in 1912 and 1913 and during the first 5 months of 1913 and 1914 respectively.

The number of automobiles imported was 5,350 in 1913, compared with 3,428 in 1912. The increased imports of trucks and chassis in 1913 may be explained by extensive orders from the Russian War Dept., but the great increase in the total imports is largely due to the Petrograd exhibition held for the first time this year.

Kinds	1912	1913	Jan. 1-June 1, 1913		Jan. 1-June 1, 1914	
	Value	Value	Number	Value	Number	Value
Automobiles:						
With 4 or more seats	$4,863,000	$7,511,000	1,754	$3,161,000	1,816	$3,543,000
With less than 4 seats	324,000	593,000	282	321,000	121	124,000
Trucks and chassis	331,000	717,000	516	352,000	315	280,000
Motor cycles	226,000	298,000	1,145	175,000	1,429	246,000
Total	$5,744,000	$9,119,000	3,697	$4,009,000	3,681	$4,193,000

Weight, Not Volume, of Air and Fuel Determines Proper Carburetion

The Automobile Engineers' Forum

Factory Engineer Points Out That Carbureter Adjustments Are Designed to Compensate for the Effect on the Mixture of Variations in Temperature and Pressure

By Frederick Purdy
Factory Engineer, Findeisen & Kropf Mfg. Co.

CHICAGO.—Editor THE AUTOMOBILE:—Concerning the relative merits of an adjustable and non-adjustable carbureter much can be said, but before going very far in this subject I want to say a few words as to the meaning of adjustable.

It must not be assumed that because there are screws that can be turned, that it is necessary to turn them. A carbureter with any number of adjustable places may be quite as fixed a proposition, after having once been adjusted, as a carbureter with rigid unalterable openings, the size of which is determined at the factory.

The impression seems to prevail that carbureters, which have the means of adjustment, must therefore, be adjusted at frequent intervals, apparently on the ground that nothing shall be wasted.

"If you have shoes, wear them; if you have a hat, put it on; if you have an adjustment, adjust it," seems to be the logic.

Why Motors Vary

It is rarely the case that two motors of the same design and built at the same time, are absolutely alike. Cylinder cores shift slightly and vary the compression space. If the manifold is cast as a part of the cylinder block, or separately, it is not always of the same area. Some present more or less friction to the movement of the air than others, and both compression and intake manifold conditions, influence carburetion. And the influence of the exhaust valves and the manifold must not be ignored.

However much care is exercised, cams are not always alike. This influences the lift of the valves, and in order to make them quiet, road testers will give more or less clearance to the tappet, which not only varies the lift of the valve, but also its timing. All this influences carburetion, so that even if a carbureter may be made for a particular motor, it may require some little variation in the carbureter itself to compensate for the accidental variables in the motor. Hence the necessity for providing these adjustments.

After the carbureter has been adjusted to its particular motor, it may be quite as fixed as though the openings had been drilled at the factory to a definite size, so that an adjustment does not, necessarily, mean something that is to be continually tampered with, but may be a provision for obtaining the highest possible efficiency from any particular motor on which the carbureter may be mounted.

It is not contended that carbureters made without the possibility of adjustment, cannot function properly. It may happen that the carbureter and the motor may be exactly adapted to each other. I said "happen." If they don't happen to harmonize, then the adjustment on the carbureter will compensate for the error. If there is no adjustment, then an inferior performance must be expected, or another combination of motor and carbureter looked for.

A properly-designed carbureter, having been adjusted once to a motor, could have its adjustable parts soldered, and it would then be quite as simple as if it were made without an adjustment at the factory, and if to make his product fool-proof is the aim of the carbureter manufacturer, he would have attained the same end should he have made his carbureters adjustable and adapt them to the motor, and then remove the possibility of further adjustment.

WILL A CARBURETER AND A MOTOR WORK TOGETHER PROPERLY WITHOUT ADJUSTMENT IN ALL CIRCUMSTANCES IN WHICH THEY MAY BE PLACED?

It is the office of the carbureter not only to partially or completely, if possible, vaporize the fuel, but to properly proportion it to the air. The proper proportions, however, should be based on the weight of the air and the fuel and not on the volume. It is the mass, and not the space the mass occupies, that determines its relative value.

To be explicit: A certain weight of gasoline should be mixed with a certain weight of air to produce a proper firing mixture. Unfortunately we are dealing with an incompressible liquid, the volume of which is varied only by temperature, and a gas, highly elastic, the volume of which is varied by pressure as well as temperature.

The Ideal Carbureter

A theoretical carbureter should, therefore, weigh out air and fuel and mix them. Then adjustments would not be necessary to compensate for different altitudes.

With such a device, a car should run as well at Palm Beach, Fla., or Helena, Mont., because, although the air is more rare at Helena, the proportioning device would take in a greater volume of air to gasoline at Helena than it would at Palm Beach.

In either place it would take in as many pounds of air per pound of gasoline, but, unfortunately, the light of present knowledge is not bright enough to show us a way to do this thing without complications and a mechanism so intricate and delicate that its use on a motor car would be absurd.

So, we perforce, resort to mechanisms which proportion by volume rather than mass, and since the volume for a given mass varies at different altitudes for the air, but does not vary for the gasoline, the device that proportions properly in Illinois, will not give the same ratio of air to gasoline in Colorado.

HENCE THE NECESSITY FOR SOME MEANS TO ESTABLISH A DIFFERENT RATIO OF GASOLINE TO AIR BY VOLUME AT DIFFERENT ALTITUDES IN ORDER TO

MAINTAIN A CONSTANT RATIO OF AIR TO GASOLINE BY MASS AT DIFFERENT ALTITUDES.

No other factor than this need enter into the problem because it has been well established that the atmosphere has substantially the same proportion of oxygen to nitrogen at all places and elevations.

Oxygen the Re-creator

The things that make a man feel better in some localities than in others, whatever they may be, certainly do not include the proportion of oxygen to other elements in the air, and it is oxygen, and not the landscape or the service in hotels, that makes the engine run, although these other things may have a big influence on the human motor.

As stated in the outset, there may be one or two or several adjustable places on a carbureter. These may be used to establish the proper relation of the mixing device to the motor at different speeds or with different loads and to provide for acceleration and several other things that enter into the problem of properly feeding the motor. It does not follow, however, that any of them must be adjusted because one travels from Chicago at 600 feet above the sea to Leadville at 11,000 feet above the sea.

Some means must be provided, however, to diminish the proportionate volume of gasoline to air to compensate for the diminished weight of the air as the car ascends from the low prairie to the high plateau.

This is done in some carbureters, notably the Rayfield, by controlling one of the nozzles delivering fuel to the carbureter by a simple mechanism on the dash or the steering post. The other adjustments may as well be soldered tight after the carbureter is once adapted to the motor.

The pressure of air at sea level is 14.6 pounds per square inch: at Leadville, which is about 11,000 feet high, the pressure is about 10 pounds per square inch. In other words, a given volume of air at Leadville will have only two-thirds the oxygen content as the same volume of air at New York.

Therefore, only two-thirds of the volume of the gasoline required to properly impregnate a cylinder full of air at New York can be properly burned in the same cylinder full of air at Leadville, and since all carbureters, without exception, proportion altogether by volume, some adjustment, to compensate for this condition, must be provided, or the carbureter may work well in New York and badly at Leadville, or good at Leadville and badly in New York.

A recognition of this fundamental truth in carburetion would save a lot of misunderstanding, and discredit a lot of flamboyant advertising to the effect, if properly analyzed, that the carbureter advertised is not under the control of natural laws, but possessed of mystic qualities quite supernatural.

So far, I have touched merely on the proportioning of the fuel. It goes without saying that in the lighter atmosphere compression is reduced in proportion to the weight of the atmosphere, and compression is one of the factors which varies the requirements of the fuel.

The Compression Factor

I shall not attempt to say just what relation the compression does have to the proportion of the fuel, it is not necessary to even guess at it. All those who are familiar with motor construction and operation know that the statement is true, and adds another reason for some compensating device under the control of the driver.

It may be stated, with truth, that an automatic device, working on the principle of the aneroid barometer, to cut down the gasoline flow in harmony with diminished atmospheric pressure, would take care of the conditions that require a manual control for different altitudes, and thus do away with the only remaining adjustment after the carbureter had been adjusted to its motor.

To the end that no inventor runs into disappointment, after working hard on the problem, I want to say that several devices of this kind have been worked out and are in the hands of the patent attorney. None of them, however, is an unqualified success, and the present method of control is so simple, and occasion for using it so rare, that there is little reason for adding anything to the carbureter.—FREDERICK PURDY, Factory Engineer, Findeisen & Kropf Mfg. Co.

Recent Court Decisions—Train Damages Car

A RAILROAD company was not negligent for not giving warning at a crossing, as a train on a crossing is warning enough.

In New Hampshire a man hired a car for a night trip. About 11 o'clock that evening the automobile collided with the fourteenth car of a slow moving freight train at a crossing. There were no gates, lights or signals, and there was no flag man at the crossing. The night was dark and foggy and the automobile was being driven at a speed of about 14 miles per hour. The motorist brought suit against the railroad company for injuries, but it was decided that he should not be allowed to recover damages, as, in the absence of a State or Municipal provision, a railroad is not compelled to give warning at a crossing and, as the train was visible 35 feet away, the motorist should have stopped.—*Gage vs. Boston & M. R. R.*, 90 *Atlantic* (*New Hampshire*) 855.

$1,741 for an Eye

The Michigan court decides that a manufacturer must pay damages to his employees, when they are not furnished with a safe place to work.

In this case one of the manufacturer's employees was struck by a flying chip from a cast iron frame, which workmen were chiselling and his eye was put out. The accident occurred while he was walking down an adjacent passageway. The employee claimed that there was a failure to provide him with a safe place to work; that the chipping was negligently done, and that there was negligence on the part of his employer in failing to erect screens and coverings, to place barriers, or to notify him of the dangerous work.

The employer, on the other hand, contended that the accident was one which could not have been reasonably anticipated; that it was temporary work which was being done unknown to him, and that the injury was caused by the act of a fellow servant.

The manufacturer was engaged in making automobiles in a large factory in Flint, Mich., and employed over 5,000 employees. It had various departments, superintendents and assistant superintendents. The assembly plant was in charge of a superintendent, and the assembly room proper was 400 feet long and 72 feet wide, with a center aisle from end to end. On the day of the accident workmen were engaged in erecting and fitting steel frames for the chassis of automobiles to rest on while they were being tested. It was found necessary to remove a triangular piece from each corner of the frame and the superintendent told his men to take it off with a cold chisel and a hammer. The man who was hurt entered the building carrying some brass and, while passing, was struck in the eye by a chip cut from the frame by the chisel.

The court held that the superintendent was the vice-principal, that is, he was the holder of delegated powers from the corporation and was not a fellow servant; that it was negligence on his part not to warn the injured man of the flying chips, or to prevent them from flying, and that the manufacturer was not relieved because the work was temporary work, and the employee could not be held to assume the risk, unless there was negligence on his part, because of his failure to notice and avoid the chips.—*Webb vs. Buick Motor Co.*, 148 *N. W.* (*Michigan*) 793.

Claims Tendency Toward Two-Cycle in Europe

EDITOR THE AUTOMOBILE:—I notice in the current technical journals there is a general tendency toward the two-cycle type of engine in Europe. There has been cited such concerns as Krupp of Germany, Carrels Fries of Belgium, Schneider et Cie., France, and Sulzer of Switzerland and numerous shipbuilders in Britain who have adopted the two-cycle. There is now a Sulzer 6,000 horsepower land six-cylinder engine in operation, so we have a power range up to 1,000 horsepower per cylinder and a 2 1-2 horsepower motor cycle. Referring to the latter *Motorcycle Illustrated* August 20, 1914, page 24, it says, "Two-stroke motors predominate for motorcycles in England. Thirty-seven out of fifty-five makers have adopted the two-stroke."

In an attempt to improve conditions in an automobile we now see eight cylinders being used to overcome the inherent defects due to cycle and yet there are concerns cited above who prefer to avoid such complication by changing the cycle (automobile engineers take notice). That this is not due to a desire to get better torque conditions and disregard efficiency is, or should be, very evident. Schneider et Cie. have built four cycles for years and after elaborate experiments decided to abandon that type in favor of the two-cycle. It might seem that it is to simplify the engine and make it more readily reversible, that in part is one reason, but Sulzer uses that type for engines of the stationary design also.

Can it be to avoid valves exposed to high temperatures? It would seem not, as all outside of Sulzer still use inlet valves in the head while Sulzer gets along with starting valves in the head and uses inlet and exhaust ports in the cylinder bore preferring to consider the least of two evils, and get an ideal combustion chamber.

A prominent authority says, "To obtain maximum mean effective pressure per revolution the two-cycle must be adopted." He might also have added to obtain maximum horsepower for a given weight and space.

This is an essential in a boat where space and weight is a factor in gross weight receipts. In the automobile, however, there is a desire to develop engines that are heavy and reduce weight by the use of aluminum and pressed steel parts instead of the more logical method of developing engines to produce the same number of impulses with one-half of the parts regardless of any fashion which in other lines changes with the season.

What special objection is there to an engine that has an ideal combustion chamber, no valves exposed to heat, cylinder air scavenged, piston air and charge internally cooled, and will deliver the same number of impulses with 1-2 the number of parts?

Cleveland, Ohio. SUBSCRIBER.

Firing Order of Cadillac Eight

Editor THE AUTOMOBILE:—Will you please explain the firing order used on the eight-cylinder Cadillac?

St. Louis. Mo. A. L. D.

—The firing of the eight-cylinder Cadillac, considering that the motor is made up of two sets of fours each being numbered 1, 2, 3 and 4; beginning at the front and counting towards the rear, is as follows:

Number 1, right—number 4, left—number 3, right—number 2, left—number 4, right—number 1, left—number 2, right—number 3, left.

This may be simply shown by the arrangement below:

Front	Right	1	3	4	2	Rear
of —						— of
Motor	Left	4	2	1	3	Motor

Each diagonal pair adds up to five and this is why this particular firing order is selected as it gives evenly distributed firing impulses about the mass center of the motor.

Differential Locks Cannot Be Attached

Editor THE AUTOMOBILE:—Can differential locks be applied to a touring car? If so, please tell me where they can be procured?

Wasta, S. Dak. A. MATHIAS.

—No. Provision must be made for the differential lock when the axle is designed. Obviously it would be a difficult matter to install a device on an axle already built which would lock the two axle members together and cause them to rotate as one.

A typical differential lock is shown in Fig. 1, where it

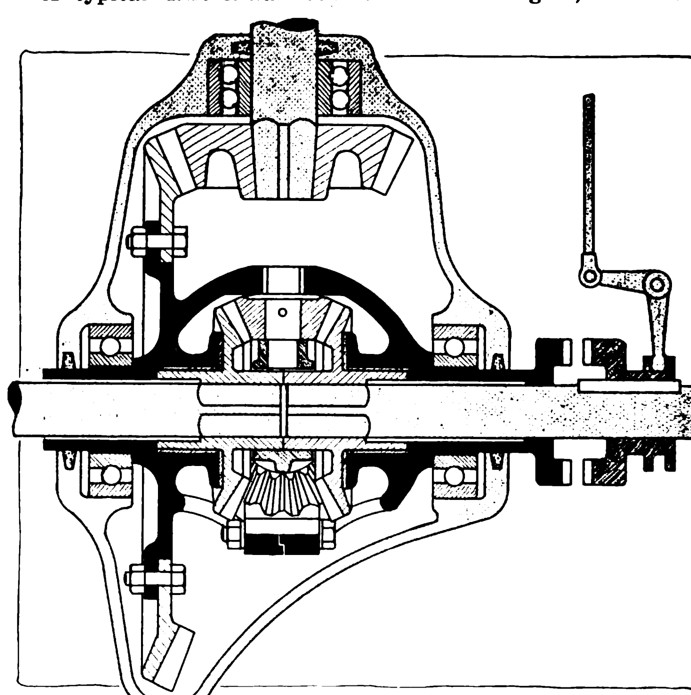

Fig. 1—Differential lock which allows the wheels to rotate together

will be noted that the dog clutch at the right locks the shaft on this side to the differential gear housing and since these two must then revolve together differential action is stopped and the other shaft must move with them.

Claims Water Will Remove Carbon

Editor THE AUTOMOBILE:—In answer to inquiry of M. Chase of Portland, Me., in your issue for November 5, as to whether water will remove carbon by dropping it into the carbureter, will say that I have been using water for removing carbon in my Hudson car for the past 2 years not by dropping but pouring it into the carbureter, a 1-8 to 1-4-inch stream being used.

My method is to open the cut-out, start the engine, allowing it to attain a fairly good speed, and pour water in the air intake, using a .5-gallon oil can with a spout so that it can be handled with one hand. Don't be afraid to pour in the water; you will be surprised to see the power that is generated through the steam that is formed together.

If you have a bad case of carbon use a 5-gallon can and set it at a convenient place near the carbureter, Fig. 2, and use a rubber tube to lead the water into the carbureter, using a stop cock to control the flow. Then start the engine as above stated and let it run for 3 or 4 hours, when you will find the carbon in little chunks back of the exhaust and there will be carbon mud in the base of the engine. After two or three treatments like this you will probably find a quart or more of carbon mud in the base of the engine. It would be a good plan to give this treatment every 1,000 miles.

Daytona, Florida. D. D. ROGERS.

Water a Good Carbon Remover

Editor THE AUTOMOBILE:—In your last issue is an inquiry from a Mr. Chase asking about the use of water through carbureter for cleaning cylinders.

I have a Marmon-32, 1910—Model F. Schebler carbureter and I have tried this with success. I let the engine run until warmed up, then drop rain water into carbureter slowly enough so as not to choke the engine. I put a pitcher full through. I formerly used kerosene, and with water a smoke is emitted similar to kerosene. The engine worked much better, stopped knocking and had improved power considerably.

This method of removing the carbon is so cheap that one is suspicious, but it has done well for me.

Warren, Ohio. T. G. DUNHAM.

Cantilever Spring Much Heavier

Editor THE AUTOMOBILE:—Several friends of mine have had discussions as to the relative strength of semi-elliptic and cantilever springs to carry the same weight. From the reactions, it seems to me that the cantilever spring must be just twice as heavy as the semi-elliptic, the other parts of the car being identical.

Oradell, N. J. A. M. WHITING.

—The cantilever spring is nearly twice as heavy as the half-elliptic. According to the simple beam theory it should need to be twice as strong, but in practice it is found that it is not necessary to make it quite as strong as this.

Here are the opinions of the engineers of some companies which are using this type of spring on the advantages of this spring and its comparative weight.

According to T. P. Chase of the King Motor Car Co., this extra weight is an advantage. He goes on to say, "Springs which we use are considerable shorter and very much wider and thicker than a semi-elliptic spring would be. Our spring is 2 1-2 inches wide and has nine leaves, whereas the semi-elliptic to carry the same load would be about 2 inches wide and have only 8 leaves.

The load carried on the rear axle is applied at the small end of the cantilever spring and when the spring is considered

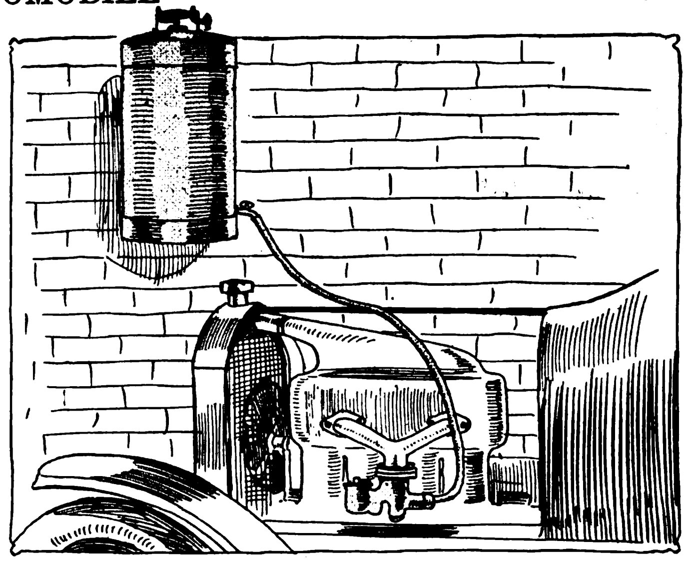

Fig. 2—Diagram showing how water is fed to carbureter by gravity

as a beam, the load at the center of the spring or at the point of attachment to the frame, is very much more than the load on the rear axle and the movement of the spring at this point is considerably less for a given amount of movement of the axle. In the semi-elliptic spring the reverse is true. The load on the axle is applied at the center of the spring and any movement of the axle caused by an obstruction is more at the end of the springs. The cantilever spring also has, what may be termed, a quicker periodicity of movement and the movement of the axle affects the lesser movement of the body for these reasons."

D. B. Webster, Assistant Mechanical Engineer of the National Motor Vehicle Co., states that, "Our experiments show that there is less rebound and side sway with cantilever springs than with the regular three-quarter elliptic. We are not able to give you any figures on this, but our impression is gained from riding in the same car equipped first with three-quarter elliptic and then with cantilevers.

"We also consider it an advantage that the cantilever spring brings the heavy strain further forward on the frame where the section is better able to carry it.

"Our experience shows that we need a stronger spring in about the proportion called for by theory."

H. J. Edwards, Engineer for the Garford Co., maker of the Willys-Knight says: "Both the fixed cantilever spring and the floating cantilever spring such as used on the Willys-Knight cars have to be of heavier section than a similar semi-elliptic spring under same load conditions.

"The fiber stress or the bending moment on the center section of the cantilever spring is without doubt double that of a similar semi-elliptic spring, as is shown by the beam theory. Cantilever springs, therefore, are of a greater section than the semi-elliptic springs. The reason why it does not have to be twice the section is that the spring does not receive the hard service and extreme flexure of the semi-elliptic. In a car with 8 inch clearance the semi-elliptic spring must be bent 8 inches while the cantilever type of spring would be deflected only 4 inches. The spring works within small limits of fibre stress and the allowable working stress in the leaves is correspondingly higher. A cantilever spring 56 inches long is equivalent in riding and springing qualities of a semi-elliptic spring 112 inches long.

"The saving in unsprung weight which is approximately the weight of the semi-elliptic spring adds also to these other advantages and is probably much underrated."

Four by Five Motor for 2,800-Pound Car

Editor THE AUTOMOBILE:—I am rebuilding an E. M. F. car. It will have a full-floating axle with 36 by 4 wheels.

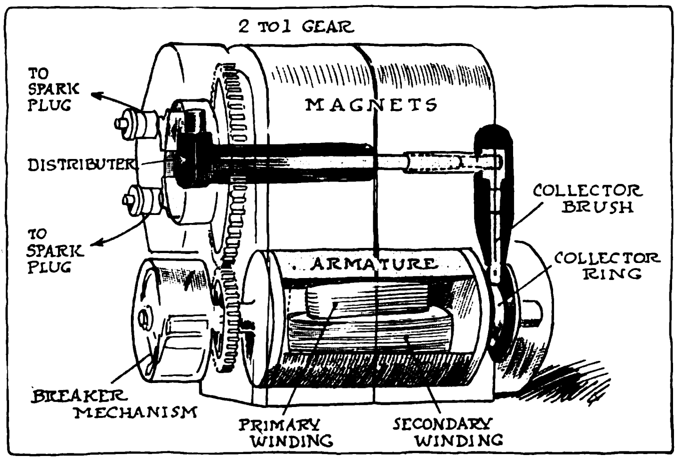

Fig. 3—Phantom side elevation of high-tension magneto

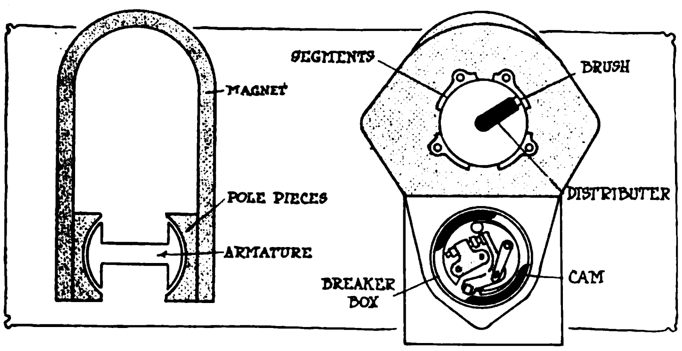

Fig. 4—Position of armature and breaker just before points separate. The armature is rotating in an anti-clockwise direction

Do you think a unit power plant with 4 by 5-inch high-speed motor will give sufficient power with these wheels geared 4 to 1? I estimate the car to weigh about 2,800 exclusive of passengers when complete.

2—If these wheels are too large what size would you suggest, 34 by 4 or 32 by 4?

Broken Arrow, Okla. DR. J. H. LAWS.

—1—This motor should develop sufficient power to make this machine speedy and an excellent hill-climber.

2—The wheels are not too large for the gear selected. Tires of this diameter also have the advantage that they will wear longer and be easier riding due to the fact that the larger the diameter the less the wheels sink into holes.

How To Wire Ford Headlights

Editor THE AUTOMOBILE:—According to your advice to J. M. Harper which appeared in the October 15 issue of THE AUTOMOBILE, on page 714, regarding the wiring of a storage battery and magneto to the headlights would you not obtain only 6 volts when the battery was switched on and 12 volts with the magneto in operation?

In this country I have never seen Ford headlights wired in parallel but always in series with 6-volt bulbs. If your correspondent has his lamps wired in parallel I can quite understand the motor stopping when he switches the lamps on.

Croyden, Surrey. F. V. MILNE.

—In our answer to J. M. Harper's letter nothing was said about voltage and therefore it was taken for granted that the battery furnished 12 volts the same as the magneto and that the lamps were also of 12 volts. Therefore the wiring diagram which we suggested and which is shown in Fig. 5 is correct. There is no reason why 12 volt lamps may not be used successfully, although the 6-volt type may be more common.

If a 6-volt battery were used in this diagram, however, the motor would not operate on the magneto, just as you suggest; because the storage battery would then act as a short circuit.

In order to use a 6-volt battery the lamps must be 6-volt and be connected in parallel on the battery and in series when on the magneto, as is indicated in Fig. 6.

Two double throw switches are used, wired as shown. The handles of the two switches must be connected together so that when one moves to the right or left the other does also. If this connection were not made there would be danger of throwing one of the switches the wrong way.

Seven-Passenger Body for a Five

Editor THE AUTOMOBILE:—1—I would like to replace my five-passenger body with a seven. Do you think the extra overhang on the rear axle would hurt the motor?

2—If a motor is equipped with a high-tension magneto, does each cylinder receive alternately one effective spark and one surplus spark?

New York City. L. J. H.

—1—The extra load will not harm the motor, if it is not allowed to labor on high gear. When it is evident that the car cannot climb a certain hill on high gear, rather than force it up, a shift to second should be made. The same applies when running on second gear and low gear is required. There is more danger of hurting the springs or wearing out the tires. Possibly it will be necessary to substitute stiffer springs. Unless the tires are amply large for the weight they are now carrying, oversizes should be put on, at least on the rear where the greater load is.

2—The ordinary four-cylinder, high-tension magneto only produces sparks when required, that is, at the beginning of the working stroke. Such a magneto produces a spark every half revolution of the armature and therefore by connecting it to the motor so that it revolves at the same speed, just the right number of sparks are generated, since a four-cylinder, four-cycle motor requires a spark every half revolution. These sparks are distributed to the proper cylinders in turn by means of a rotating brush.

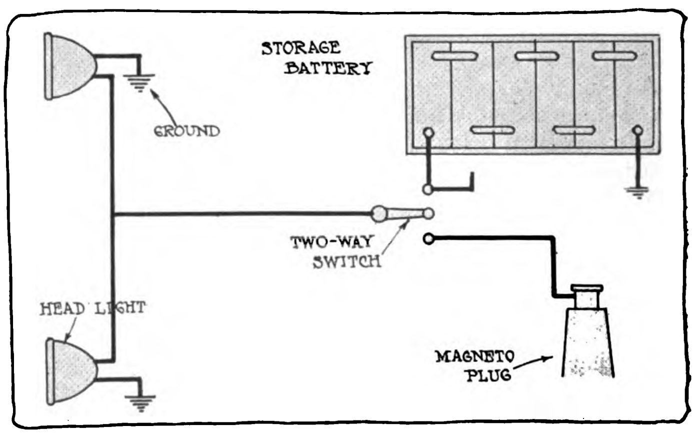

Fig. 5—Ford wiring diagram with 12-volt battery and 12-volt lamps

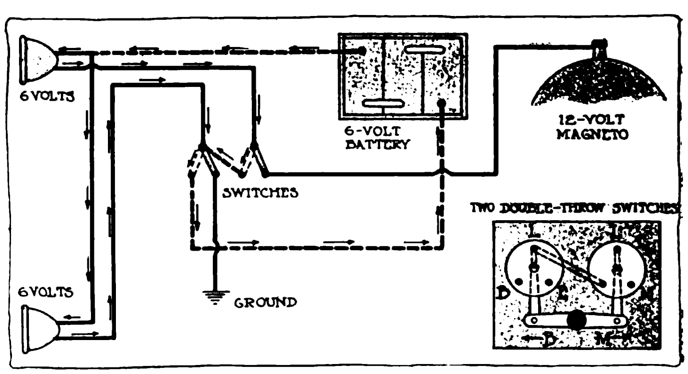

Fig. 6—Ford wiring diagram using 6-volt battery and lamps

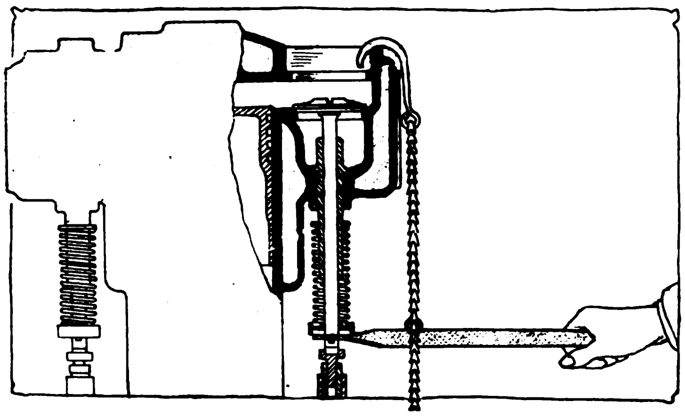

Fig. 7—Pierce motor, showing method of lifting valve spring to remove key holding spring seat

The complete mechanism is shown in Figs. 3 and 4.

The current is generated in the armature which consists of a few coils of wire in the slots of the H-shaped core. The armature core is made of iron and lies between the ends of the large magnets which give the instrument its name. Whenever the armature is in the position shown in the figure a maximum current is being generated in it due to the fact that it is moving, with greatest rapidity, through the magnetic lines of force passing between the iron pole pieces. When the armature is at right angles to this position, the wires of the coil are entirely out of this influence and no current is generated.

With the armature in about the position indicated, the spark is produced when the circuit is broken by the separation of the breaker points. When these points fly apart; impelled by the cam shown, the current dies down in this circuit. This causes a high voltage to be generated in the secondary circuit. The latter has no electrical connection with the former, but is magnetically linked. The primary coil which forms part of the primary circuit is inside the secondary coil which forms part of the secondary circuit. In the magneto shown, the primary coil and the armature winding are one, the secondary coil is directly outside of it and all rotate together.

The current is distributed to the proper cylinder by means of the rotating brush which makes consecutive contact with the four segments which are connected to the high tension wires running to each of the four cylinders. The distributer runs at half the speed of the armature and the two are positively connected by gears. The two are so set that the brush is in contact with one of the segments when the breaker points separate and the spark occurs.

How To Grind Pierce Valves

Editor THE AUTOMOBILE:—1—I have a Pierce-Arrow car and would like to know the best method of grinding the valves.

2.—How should I prime the motor.

Baltimore, Md. JOHN E. BROOKS.

—1.—First remove the valves which require grinding. The ones which probably need grinding are those which do not hold the compression. The compression of each cylinder may be tested by opening the priming cocks on all the cylinders, but this one and noting whether an increasing resistance to cranking is felt as the piston of this cylinder progresses upward on the compression stroke. If not, compression is leaking and the most likely place is past the exhaust valve although the inlet valve may be at fault or possibly there is a leak past the rings.

Having determined those exhaust valves that probably require grinding, the next step is to remove these valves. The valve caps are unscrewed, and then by the aid of a valve spring lifter as shown in Fig. 7 the key holding the spring seat of each valve in place is removed. This is done by installing the valve spring lifter as shown, then by pressing down on the handle the spring seat is raised and the key may be withdrawn with the other hand. It will be easier to do this when the valve is seated, as the spring is fully expanded then and is therefore easier to compress.

The removal of the valve is next. Start it upward by inserting a screw driver between the valve stem and the valve tappet, or else turn the motor over until the valve is fully opened. After the valve is raised off of its seat by either of these methods it may be withdrawn by slipping a piece of string around the head.

Withdraw the valve spring by grasping it firmly with both hands and working it out over the push rod.

You are now ready to begin the grinding operation. Coarse and fine emery powder mixed with enough cylinder oil to form a thin paste may be used as a grinding material or a suitable grinding paste may be procured from any supply dealer.

Apply a small amount of the coarse variety to the seat of the valve, replace it in the motor and using a screw driver rotate the valve back and forth through a small angle several times. Raise the valve from the seat, give it a quarter turn, and then repeat the operation. The valve may be raised by hand or a weak coil spring may be placed under the head so that the moment the pressure of the screw driver is removed the valve flies up.

The object of the grinding is to remove pits in the valve and its seat as shown in Fig. 8. After these have been ground out, the surfaces should be polished by using fine emery or paste. Be careful not to get any of the grinding substance on the stem of the valve for it will wear the guide.

When the grinding is finished, the surfaces must be carefully wiped clean so that every vestige of the abrasive has been removed and then the valve mechanism should be reassembled.

Then clearance between the valve stem and the push rod must be readjusted. The clearance should be sufficient to allow the insertion of a sheet of writing paper. This adjustment is made by turning the screw in the top of the push rod to the right or the left, as the case may be, after the lock nut directly below it has been loosened.

2—Unless you use a special priming device the best way to prime the motor is to inject a small amount of gasoline into each cylinder through the priming cups. A teaspoonful for each one should be enough.

Buick C-25 Sells for $950

It was stated in the October 15 issue on page 715 that the price of the Buick model C-25 for 1915 was $1,050. This should have been $950.

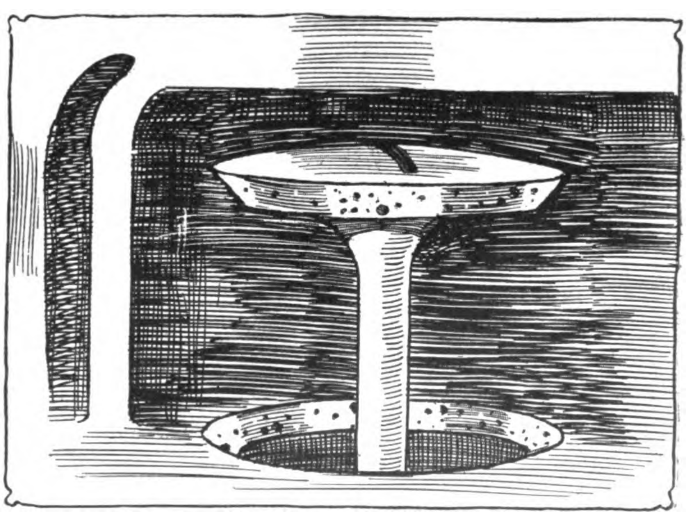

Fig. 8—Pits in valve and seat which cause loss of compression

American Motor Vehicles for the Belligerents

With Special Reference to 1915 Needs of Russia

OFFICIALLY Russia is no longer in the market for American motor trucks or automobiles, having bought all wanted for the present. It is desired to gather some experience first with these vehicles of different manufacture before formulating requirements for further needs, as their suitability for the local conditions cannot be ascertained for some time to come. It is considered very unlikely that it should prove possible to utilize motor trucks to advantage during winter and spring on the poor roads of Galicia, Poland and East Prussia. No adventurous propositions are entertained, as no emergency is recognized. Russia's Commissioner, Baron de Korff, and the military attaché, Colonel Golejevsky, warrant no information of more detailed nature.

Unofficially, the case stands differently. All are at liberty to theorize about Russia's wants and to strive at anticipating them, and it will be desirable for all concerned if any action taken, on this basis, for supplying the wants of the future happens to fall in line with the instructions which the Russian purchasing agents eventually will receive from their government. Communications on the subject will naturally be placed on file in the meantime.

The field is thus open for speculation, and as war time is notoriously liable to sudden changes of conditions, some of the elements upon which a considerable amount of business may depend command a timely and actual interest.

The inaccessibility of Russian ports during the winter almost closes the empire against immediate deliveries. Archangel, the port on the Arctic ocean which is reached by passing north of Norway and Sweden, can probably not be kept open much longer, even with icebreakers. The energetic use of ice-breaking vessels is under consideration, however. Petrograd (St. Petersburg) can receive goods only at great risk so long as Germany controls the Baltic and the precarious definition of contraband makes it difficult to ship through Norway and Sweden.

Odessa on the Black Sea is an inland city unless means are found to pry open the Dardanelles and the Bosphorus for the passage of war supplies. There remain Vladivostok and Port Arthur. The latter is ice-free and under Japanese control. Only in a great emergency could it be contemplated to ship motor vehicles, even unassembled, from American manufacturing centers to San Francisco, thence over the Pacific Ocean to Port Arthur and from Port Arthur over 7,000 miles of Manchurian and Siberian railway to Petrograd. These conditions alone would dictate a waiting policy with regard to the ordering of motor vehicles for the present, but a change in the relations of Turkey and the Balkan states to the war might open Odessa, (a chance much enhanced by Turkey's actual entry in the warfare, which took place shortly after these notes were written), while one affecting Denmark or Sweden or both these countries might open or close the northern route definitely, even after the breaking up of the ice, next year.

From the reports of the war in Belgium and France it seems clear that motor trucks are principally used for the commissary department and for the transportation of ammunition and rapid-fire guns; to some extent also for the hauling of field ordnance, but the trucks used for the latter purpose are mainly of the four-wheel-drive type, which cannot yet be made in large numbers in the United States. The lighter types of vehicles and especially ordinary automobiles in all sizes are employed on a large scale to expedite the movements of troops, not only for getting them from the rear to the front but in ever increasing measure also for effecting tactical changes along the much extended firing lines. In many instances trucks and omnibuses have served to rush troops forward and have afterwards doubled on their tracks to fetch more ammunition and food from the rear. On account of the long battle formations there has been no real rear guard in this war but only strings of detachments for protecting the lines of communication, the railways and the roads, the bridges and culverts.

While it is unlikely that Russia has contemplated the extensive use of ordinary automobiles for the purpose of gaining strategic advantages through a great rapidity in the movement of soldiers or for saving them from fatigue, there is no doubt that her generals have been at a disadvantage in this respect and that motor vehicles would be so used, if they could be had. But staff officers, aides and couriers have absorbed the supply of automobiles on hand. The winter campaign must be fought without more extensive use of them, but Russia is fortunate in being able to put two men in one place rather than one man in two places and thereby make up to some extent for her shortcomings in this feature of transportation equipment. The massing of enormous numbers will do for defense, but for offensive operations a high degree of mobility is required, and if the lessons in latter-day warfare taught so far are accepted it can therefore be taken for granted that Russia, if she can hold her own, will want just as many automobiles and trucks in the spring as she can get.

All Sizes Needed

The question of their weight and capacity is paramount and intimately connected with the road conditions. The German and French view, greatly favoring the large unit—very substantial, large and heavy, yet limited to an axle load of about 6,000 kilograms maximum—seems still to be shared in Russian official circles, and it is in accordance herewith when military representatives place great emphasis on the avoidance of skidding, which is far more serious for heavy than for light vehicles, but the lessons of the present war on Belgian and French soil do not go in the same direction except where the traction of heavy ordnance is involved. On the bad roads of the eastern country the light vehicles will necessarily prove even more indispensable for mobility than they have proved in the summer season on the western arena whenever macadamized roads had to be left behind. The saving in drivers' wages which operates so strongly in commerce to keep the capacity of vehicles up to the largest which the roads will support, is of course entirely eliminated. In the military operations drivers can be had in plenty and a sufficient number of men is always on hand to help a vehicle out of any temporary predicament to which it may become subject or to ease it over an impassable piece of territory, provided the vehicle can make up for the trouble by the speed it makes possible under average conditions.

It is apparently not quite the correct idea that the 1 1-2 ton truck is coming into demand for these reasons in preference to the 3-ton and the 5-ton trucks. The lighter type of truck is still too heavy for meadows and wet ploughfields, and for good roads the heavier truck is preferred, but in Russia the light truck will no doubt be demanded for all transportation work among the reserve forces and most when fitted with a stake platform which affords handholds for soldiers and can be readily adapted to many different purposes. Nearer to the battle formations, however, all results point now to the additional need of much smaller units; to the great superiority of five or six chassis rigged up to carry from 1-2 to 1 ton, each, of either dead or live load in any helter-skelter manner as compared with a corresponding load capacity in the form of one or two 3-ton or 5-ton vehicles—especially as the latter have plenty of work elsewhere. Such chassis, which can be turned out in great quantity in this country on short notice, have the most advantageous contact area of the wheels with the ground, to secure traction, and can be helped out of a difficult spot in a jiffy by its occupants, while the more numerous occupants of a heavier vehicle cannot find spots enough for applying a boost proportioned to its weight.

An Austrian lieutenant acting as despatch bearer in the Galician and Polish campaign relates how his little car, of the Wanderer model, proved to be the only one of all the motor vehicles of the army corps which remained in commission in the broad zone of forests and bogs at the Galician frontier. Writing on September 16 he relates: "After the first three weeks I had learned to be glad when I was only required to drive through a potato field. Morasses, quicksand, forest bottom with tree stumps, roads with an endless succession of holes in which the wheels sank to the hubs, now on the right side and now on the left, and again on both sides at the same time, made it impossible for days on end to change from the low to even only the second speed." Finally a Russian shell demolished the car after five weeks of service. (From October 10 issue of *Allgemeine Automobil-Zeitung.*)

It is plain that the theories relating to military motor vehicle service which had been formed on the basis of antebellum maneuvers have been profoundly changed and widened through the actual war tactics, in which the protection of the artillery against flank attacks plays an enormously important part, necessitating a new sort of mobility parallel with the lines of intrenchment extending for hundreds of miles, nearly at right angles with the direction of advancement or retreat.

Only automobiles, in the smallest possible units, and bicycles render this mobility practicable, while the use of the same class of light vehicles for the general transportation work of the armies is scarcely secondary to that of the larger motor vehicle units and the railways. The whole military motor vehicle field is suddenly found to have been greatly extended.

To the American automobile industry this condition, which has barely reached official notice as yet or been fully appreciated in its practical consequences, may soon result in extraordinary activity, as no other country can produce small motor vehicle units with anything approaching the rapidity of production which can here be realized. But it stands to reason, perhaps, that the runabout chassis which may be demanded in large numbers, at almost any time from now on, should be protected against the severities of the service to which they may be exposed. Probably the springs should be strengthened and lengthened (so as to retain all their flexibility) and provided with rebound checks. Probably simple platforms should be provided instead of the ordinary bodies. Perhaps the tires should be solid and anti-skidding.

The possibilities for shipping the vehicle parts unassembled, with an assembling crew to put them together at their destination, also form an interesting subject for speculation on which the foreign purchasing agents may be able to give pointers as soon as their governments are ready.

A boom in second-hand vehicles is not excluded. If the demand should come with the suddenness and insistence that is foreshadowed by the events, an organization able to place thousands of inspected and classified small motor vehicles at disposal on short order would be entitled to a hearing.

As an example of the conditions in Russia which should make the use of motor vehicles of almost any description highly desirable, it may be mentioned that nearly all of the Russian railways have tracks which are 3 1-2 inches wider than those of the Prussian and Austrian railways with which they connect, so that unloading and reloading are required at the frontiers, and that even such towns in Russian Poland as Lomsha, with 22,000 inhabitants, and Pultusk, with 16,000 inhabitants, have no railway facilities whatever. With regard to the transportation of troops and military materials, the Russian preparations have been for a defensive and not for an aggressive campaign.—M. C. K.

British Army Truck Efficiency

By J. M. C. Rowley

HAVING referred in last week's issue to the German armored cars which I saw at Ostend, I should add that their capture from the enemy may have been due to the poor protection they afford the driver against a flanking fire. They are, however, quite formidable looking and dash about through quiet villages, their three great headlights terrorizing the inhabitants. The radiators did not seem to be protected in any way, but there is a powerful buffer to protect them from impact. One or two radiators were perforated by bullets, although I could not get near enough to trace the passage of the bullet and find whether it had vitally affected the motor. One thing was plain. An armored car of the German description is very easy to make from an ordinary touring body. In British service several Ford cars are being fitted with ambulance bodies and they are doing excellent work in this connection.

I have just met some motor transport drivers and learned many interesting facts regarding the work of motor transports. Motor transportation back of the firing line is exceedingly well organized, the vehicles supplying the troops with food, clothing and ammunition. The constant supply of the latter to the artillery corps insures the incessant continuance of artillery attacks which has characterized the present war.

Formerly the connection of a long line of troops was made by railroad, but today the motor bus enables the whole army, soldiers and transport, to move together as a unit. The railroad is not by any means dispensed with, and so far as it goes, is used for the transportation of all kinds of material and supplies. In the present campaign, the railroad, however, is not the governing factor in the movement of troops. The supplies are removed from the trains to the 3-ton motor wagons, and these follow the troops wherever they go. In this way the army is kept constantly supplied with rations, the soldiers having 2 days' food supply, and the trucks carrying supplies for 2 days more. All the movements of the trucks are in strict accordance with schedule arranged by the army service corps. The motor trucks meet the trains and the motors are in turn met by the horse wagons, which convey the supplies direct to the firing zone.

In conversation with one driver who had been several times in the fighting zone with his motor truck, he said: "I carried ammunition and distributed it to the artillery corps, ranged on a slighter elevation over against the German trenches and earthworks. Practically all the time my truck was under fire, but the marksmanship was poor and although one or two stray bullets and pieces of shell hit the truck the steel plates were not damaged. I passed through safely and returned to the point from where I started by another route away behind the firing line." The truck driven was a regular war-office machine painted gray and with stout metal defenses around the whole motor and body. The ordinary motor suffers a great deal under fire if it is not protected in any way. I have seen huge masses of débris, wheels, smashed bodies, crushed motors, bent axles, etc., along the roads over which I passed. It seems that in many cases motors have been purposely destroyed. A truck perhaps forming one of a long convoy goes wrong, and the enemy is close behind. There is no time to repair the trouble and rather than allow the machine to fall into the hands of the foe it is destroyed as quickly and as thoroughly as possible.

Perhaps this will be known in history as the great motor power war.

Zenith Tests on Dynamometer Set

Complete Laboratory Equipment Devoted to Carbureter Trials

THE newly equipped testing laboratory of the Zenith Carbureter Co., Detroit, Mich., is located in one end of the new plant, and includes a complete Diehl electric dynamometer outfit. This apparatus is very similar in principle to the A. C. A. testing apparatus in New York, and could be used for just as accurate and exhaustive testing.

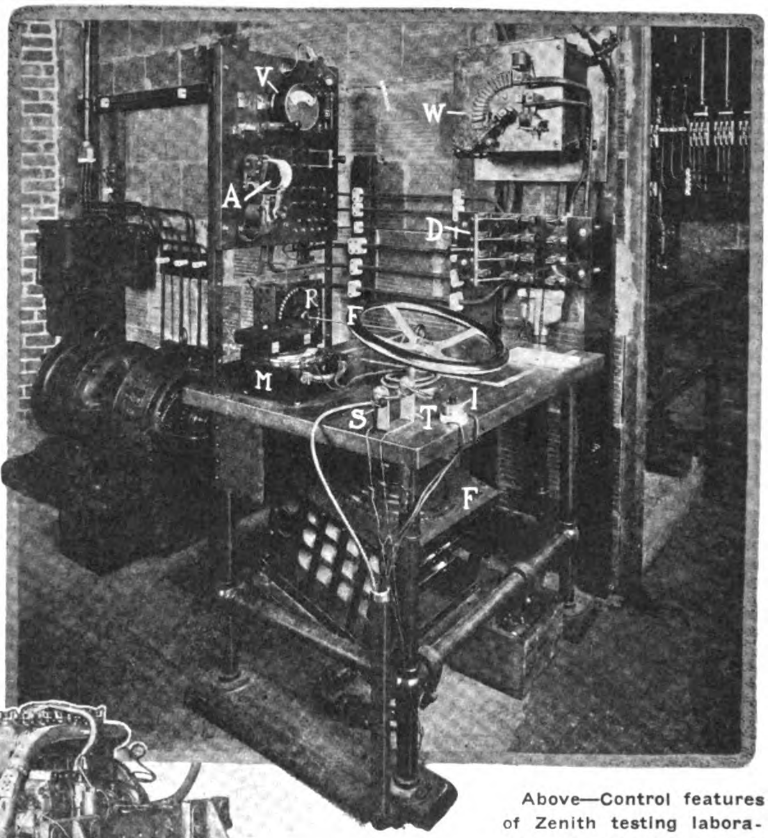
Of course, for carbureter testing, such an equipment acts only indirectly, in that the dynamometer records the power output of the gasoline engine to which it is connected, and its power output is in turn dependent to a large extent upon the carbureter furnishing it with fuel.

The gasoline engine connects directly to the armature of the electric dynamometer, and when the latter is driven by the engine, the armature tends to revolve the field, or outer part of the electric machine along with it due to the magnetic attraction between the two parts. The field portion is free to turn on its bearings at either end, and it is separately excited by the current from a transformer set which is a part of the equipment because the dynamometer requires direct current whereas the city supply is alternating. But the field of the dynamometer is attached by a link connection to scales, and the force necessary to prevent its revolving with the armature is thus measured by the scales, and is an indication of the power being put into the machine by the gasoline motor, the force, speed and so on being taken into consideration in figuring the horsepower by formula.

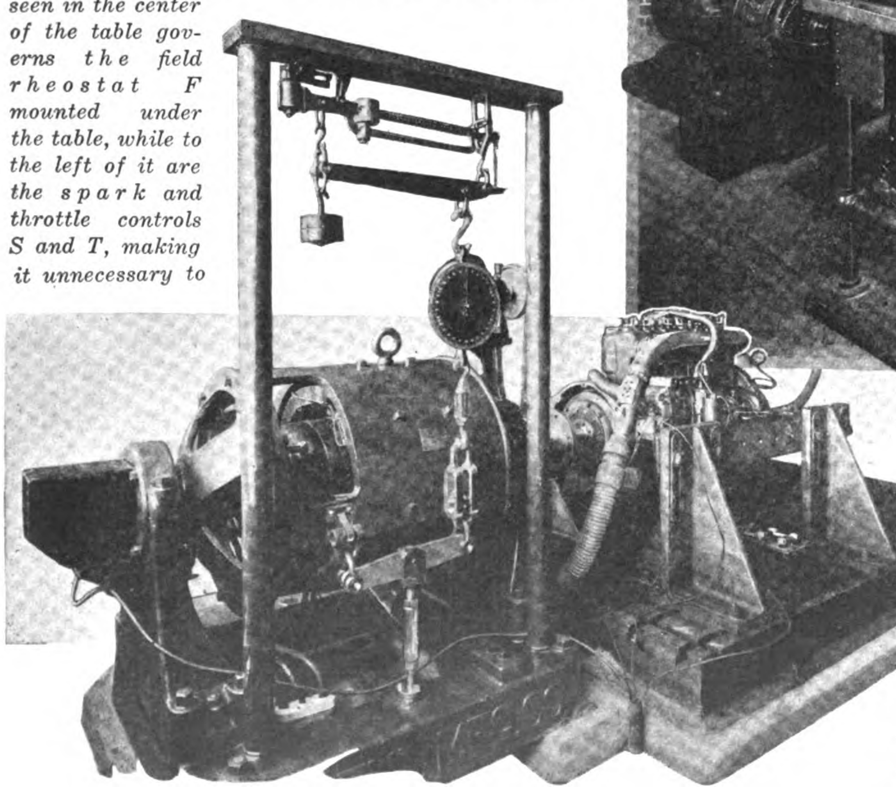
In one of the illustrations is shown the grouping of the various controlling and indicating apparatus on the table and on the wall and switchboard to the right and in front of the table. The hand wheel F seen in the center of the table governs the field rheostat F mounted under the table, while to the left of it are the spark and throttle controls S and T, making it unnecessary to step over to the motor to regulate them. Just in front of the wheel is a switch I which may be used to shut off the ignition current. An electric tachometer M records the dynamometer speed.

Without moving his position, the operator may also regulate the supply of cooling water to the engine, while at his right is the main double-throw switch D which, in one position, sends current into the armature of the electric machine so that it may be operated temporarily as a motor for starting the gasoline engine, while in the other position it loads the armature by sending the generated current into the resistance coils, the machine then acting as a dynamometer. Above this is the starting switch W for starting the dynamometer as a motor after the main switch is thrown in.

On the switchboard is a rheostat R for adjusting the transformer set voltage. The board also carries the voltmeter V, dynamometer circuit breaker A, etc.



Above—Control features of Zenith testing laboratory. A, automatic switch which cuts in when double throw switch D is swung to dynamometer position. F is the field rheostat and the wheel F is hand control for same. W is the switch starting the dynamometer as a motor. S and T are spark and throttle controls. I is the ignition switch, M the tachometer and V indicates the voltage of the transformer set, which is adjusted by rheostat R.



Right-Left—Motor mounted for testing by Diehl dynamometer in Zenith carbureter plant.

Gray & Davis Ford System

Two Units in One Case —Drive by Silent Chains —6 Volt, Single Wire

A COMPLETE starting and lighting system for Ford cars has been brought out by Gray & Davis, Inc., Boston, Mass., as was announced briefly in the Nov. 5 issue of THE AUTOMOBILE on page 872. The complete outfit, including starting motor generator, battery and wiring sells for $110. The system is a 6-volt, single wire type, and the starting motor and electric generator are distinct units, although mounted in one casing, the motor being placed above the generator. The whole device is very compact, the regulator and switch being carried on the top of the main unit. Connection to the crankshaft is made by silent chains. By pressing the starter pedal or button the switch is closed and the motor is cranked at a speed of 75 to 100 revolutions per minute depending on the condition of the motor, the viscosity of the oil, the temperature, etc.

Voltage regulation of the generator is accomplished by means of inserting resistance in the field circuit as the speed increases. This is done by means of a solenoid which operates on two resistance coils, the one being brought into circuit at medium speeds and both being switched on at high speeds.

60 Ampere Hour Battery

The storage battery is a 6-volt, 60-ampere hour of Willard make. It is charged by the generator at speeds above 12 miles per hour. Below this speed the cutout regulator automatically breaks the circuit, thus preventing the battery discharging. Below this speed the generated voltage is less than the battery voltage and therefore current would flow from the battery through the generator windings, operating it as a motor if the circuit were not broken by the cutout.

To go with this system the company has brought out a set of headlights which sells for $11 per pair and a tail light which retails at $2. The headlights give 15 candlepower while the tail light is equipped with a 2-candlepower bulb.

The attachment of the system requires little or no fitting, and the removal of very few parts. The radiator, the fan and bracket, the starting crank and the fan driving pulley are the main members that must be removed.

Then the driving sprocket is mounted on the crankshaft and the starting crank attached. The first and third cylinder head bolts are taken off and the raised part of the casting is chipped to the level of the machined surface of the hole to provide a seat for the upper bracket support. The third and fifth crankcase bolts are taken out and a place is similarly made of for the lower bracket support. The starting and lighting units are then put in place.

The horizontal chain may be adjusted by turning an eccentric bushing at the left side of the sprocket holder, while the vertical chain may be taken up by turning the adjusting screw on the under side of the bracket.

In the diagram herewith the wiring of the starting circuit is indicated by the heavy black lines. This part of the circuit is of the double-wire type, but the remainder of the system which comprises all the lighting circuits is wired singly, the return connection being through the frame. When the dynamo is in operation current flows from it to lighting switch and from thence to the lamps but when it is not, the cutout regulator breaks the circuit, and current is furnished by the battery.

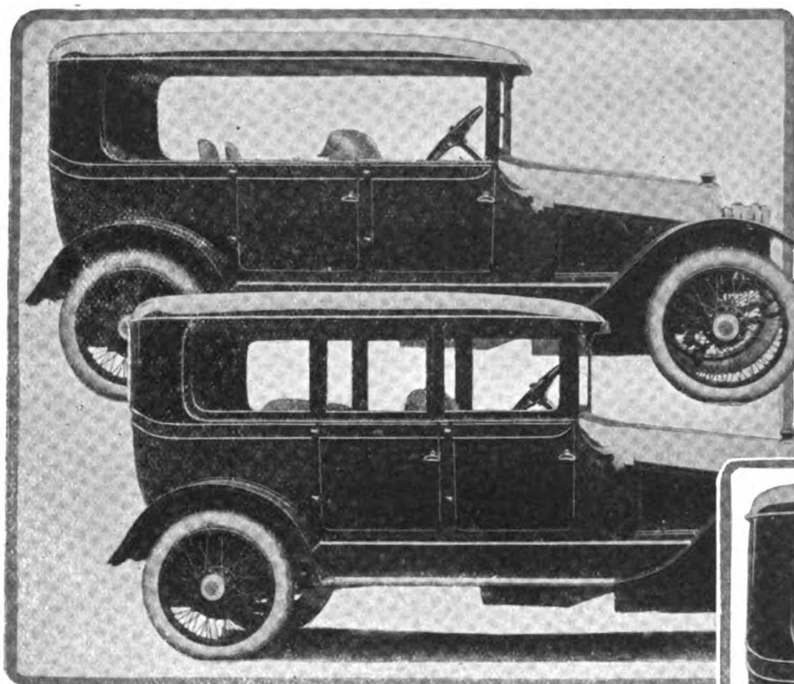
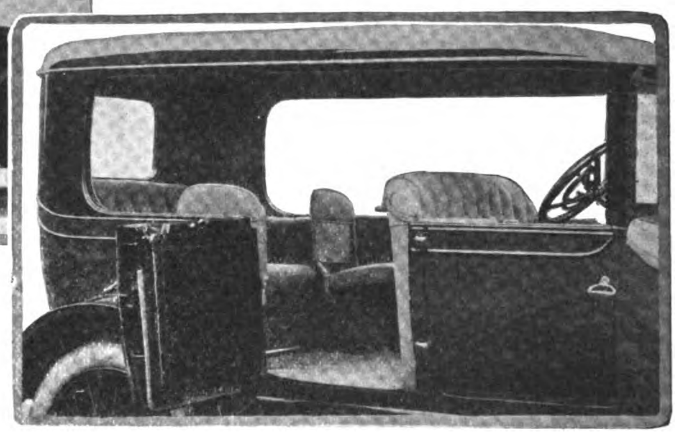
Convertible Body with Permanent Top

New Springfield Design Built in All Styles—Resembles Previous Models Otherwise





Upper—Springfield convertible body with sides down. Lower—Body with sides up giving full protection against the weather. Right—Detail showing seating arrangement and upholstery

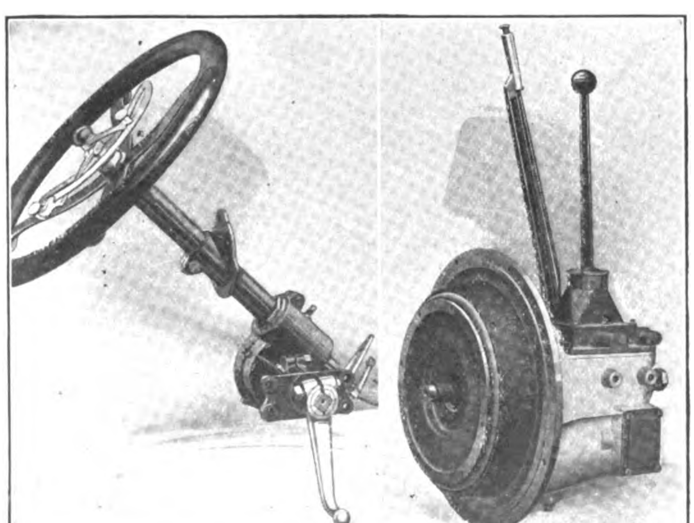
A CONVERTIBLE body with permanent top is the latest product of the Springfield Metal Body Co., Springfield, Mass. This departure in design was due to the fact that there are a great many people owning convertible bodies and open touring cars who never lower their tops. To these people this new design will appeal as it obviates the trouble of raising or lowering the top. The top, since it is permanent, provides a strong support for the sides, and it is a simple matter to change the car from an open to a closed type or vice versa, without leaving the car. All the advantages of the open touring car are obtained because with the sides down the view is unobstructed and the flow of air is unrestricted, yet when the sides are put in place protection against the coldest weather is afforded.

The permanent top may be had on any Springfield convertible body; the two-door sedan type; four-door; five-passenger, and the four-door six or seven-passenger. The list prices of these bodies, mounted, are: $975 for the two-door sedan type; $1,400 for the four-door five-passenger, and $1,500 for the four-door seven-passenger machine with this type of body.

Warner Gearset and Steering Gear for 2,400-Pound Cars

TWO new parts have recently been brought out by the Warner Gear Co., Muncie, Ind., for cars weighing around 2,400 pounds. One is a selective gearset known as model T 39 and the other is a steering gear model S 10.

The gearset is a three-speed and reverse type with cone clutch and center control and designed for a unit power plant construction. The control levers may be mounted directly above the case or at the rear as desired. The shifting mechanism is carried in a separate casting which forms the cover of the case. This is readily removed and gives easy access to the gears and bearings. An interlocking arrangement positively locks the gears in and out of mesh.



Warner steering gear and gearset for cars of about 2,400 pounds

The gear case is of aluminum. The gears are three and one half per cent. nickel, forged steel, 6-8 pitch and .625-inch face, mounted on alloy steel shafts. The main shaft is of the four spline type, thus holding the gears rigidly in position when in mesh. Annular bearings are used in mounting the mainshaft while the countershaft is keyed to the gears and rotates on plain bearings.

The control lever is a one piece forging, of the ball and socket type, with the lower end acting directly on the shifting forks with no connecting parts between.

The clutch is a leather faced pressed steel cone, spring cushioned to give gradual engagement and avoid grabbing.

Clutch Spinning Prevented

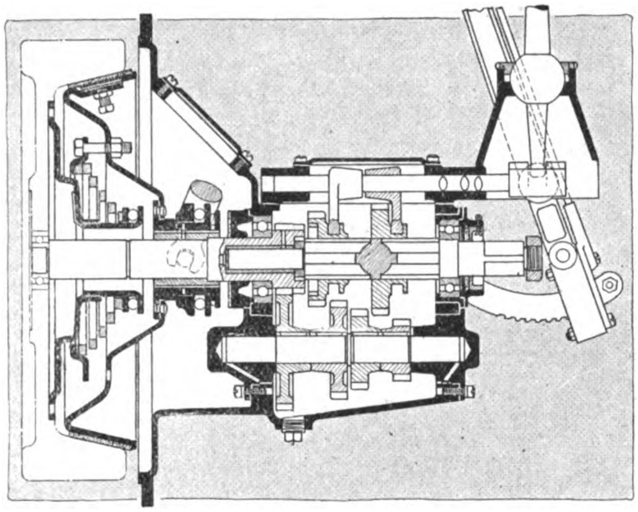
The light construction used insures against clutch spinning and this is further prevented by use of a brake mounted on the clutch shaft. Thrusts are taken on ball thrust bearings, and all wearing parts are hardened to insure durability.

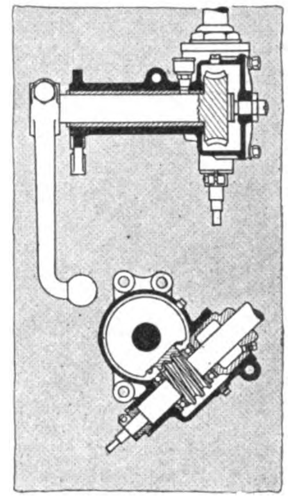
The clutch is run dry and allowance for oiling the bearings from the gear chamber is provided by a hole drilled through the center of the clutch shaft.

The Steering Gear

The steering gear is of the fore and aft steering type. It is a worm and full gear design, with allowance made for outside adjustment to take up the wear between the worm and gear.

Both worm and gear are of heat-treated steel, accurately ground to size.





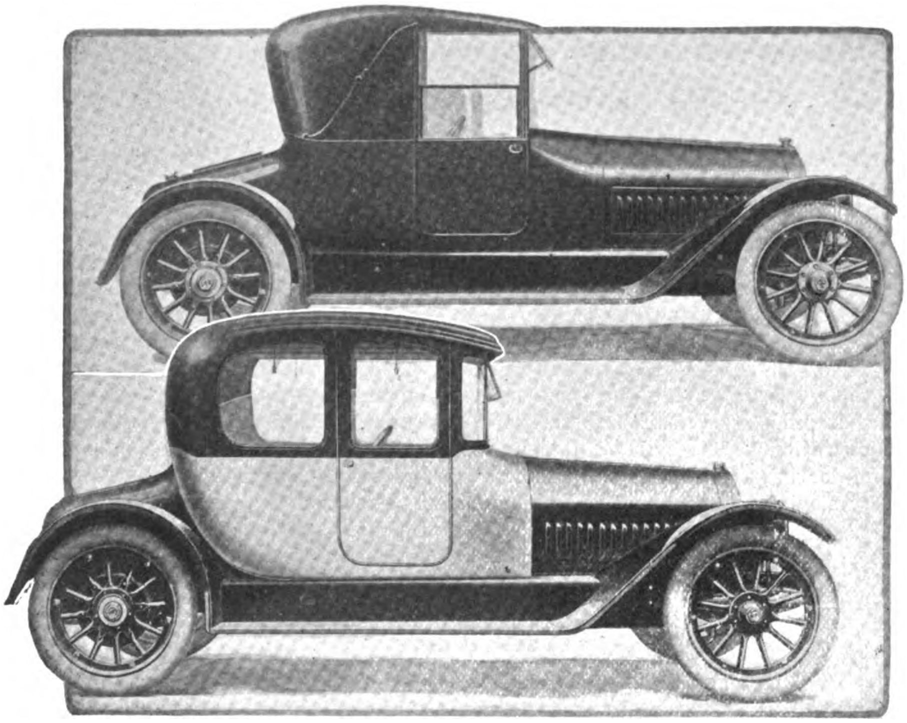
Left—Section through new Warner gearset. Right—Plan and elevation of Warner steering gear

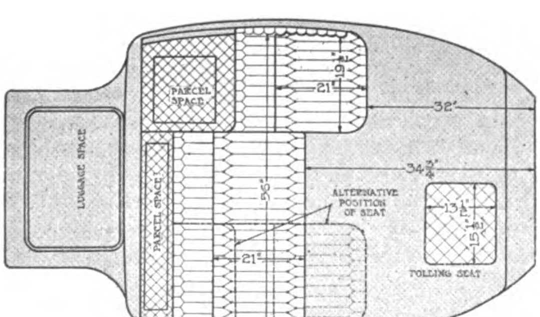
The thrust of the worm is taken at both ends upon ball thrust bearings, thus insuring ease of action.

The finish is black enamel, with the controls mounted on the wheel in nickel.

A large hard rubber electric horn button is mounted centrally above the control levers. A 17 inch stained rim is used on a black enameled malleable spider. Sections and exteriors of both the parts described are shown in the illustrations.

National Has New Coupé and Cabriolet Bodies





Top—1915 National cabriolet on Series AA chassis. Below — Four-passenger coupé. Bottom —Diagram of optional seating arrangement in the latter

INDIANAPOLIS, IND.—Two 1915 closed car models, both of which are constructed on the standard six-cylinder chassis, have been announced by the National Motor Vehicle Co. of this city.

The coupé is a real four-passenger car being considerably larger than the usual coupé body. It lists for $2,850 complete. An option of seating arrangements is offered, as illustrated by the accompanying diagram. Three passengers are carried on the main seat which, if desired is arranged in a staggered fashion, the center seat set back of the others, similar to the style adopted by some of the electric makers.

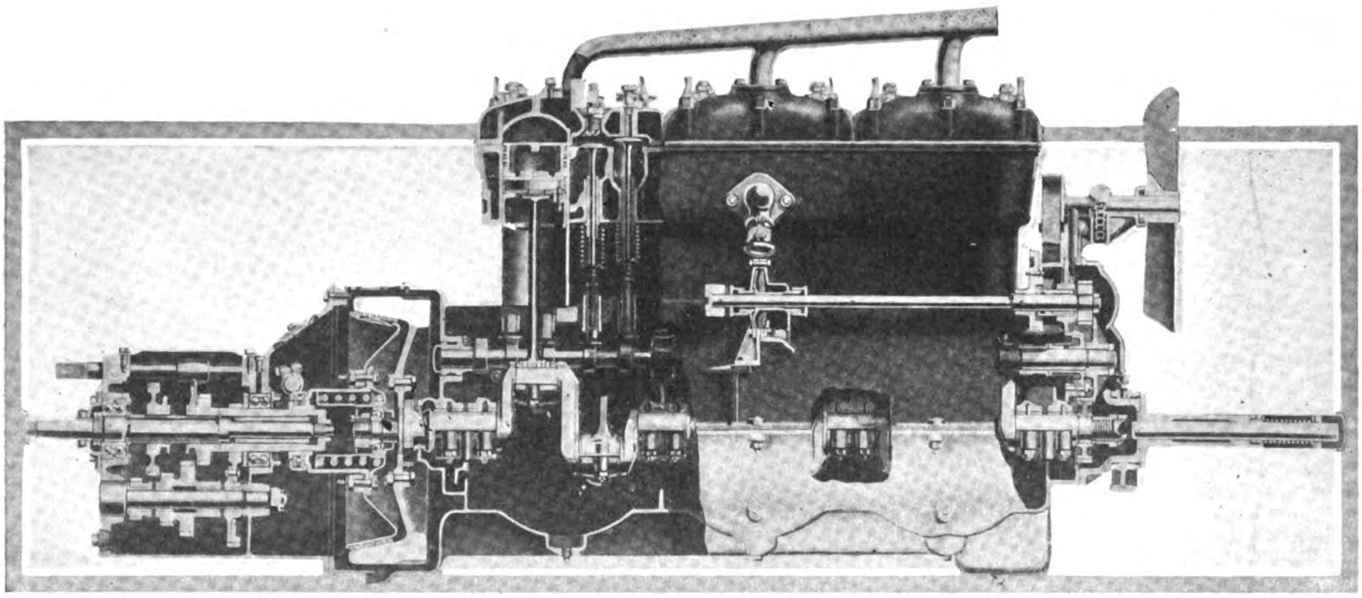
An idea of the seating arrangements possible with the coupé may be gained from an inspection of the diagram at the bottom of the illustration. The dotted lines show the alternative position of the seat at the right. The diagram is placed immediately below the coupé in such a way that one may see just how the body fits on the chassis.

Two package compartments are provided inside and a large luggage space is accessible from the outside. Choice of color, finish and upholstering is offered without any extra charge.

The National cabriolet is constructed on the series AA roadster chassis and lists for $2,700. It accommodates three passengers.

The upper part of the body is of genuine leather, especially finished to withstand the weather. According to the company, it is absolutely waterproof and does not crack.

The top folds back easily, and the glass of the doors lower into the lower half. The top part is inclosed with a neat covering, giving the car the appearance of the regular six roadster.



Part sectional view of Northway unit power plant used in the new Paterson six. The bore and stroke of the motor are, respectively, 3 1-2 and 5 inches. Note detachable cylinder head

Paterson Adds $1,495 Six—Reduces Four

Smaller Model Cut to $1,095—New Block Motors 3½ x 5—Detachable Cylinder Heads—Floating Rear Axle—Only Chassis Change in Four—Electric Starting and Lighting

THE W. A. Paterson Co., Flint, Mich., has added a six-cylinder touring model at $1,495 and is continuing its low-priced four-cylinder car at a reduction from $1,197 to $1,095. Last season only the four-cylinder chassis was supplied, on which either a touring or a roadster body could be had, but manufacturing policy of specialization has led to the abolishing of roadster models, only the two touring bodies being listed.

The Improved Four

In the continued four, the motor has been somewhat redesigned to give more power due to higher speed of operation, and a floating rear axle replaces the former semi-floating construction. The body lines have been improved by sloping the bonnet into the cowl.

The four has a wheelbase of 112 inches and is equipped with 33 by 4 straight-side tires, and the six wheelbase measures 124 inches and its tires, also straight sided, 34 by 4.

Northway Motor Used

Motors are of the latest type and conform to the same features of construction, the six being larger and stronger wherever necessary to accommodate the two additional cylinders. Cylinder heads are detachable and the cylinders cast in blocks of L-head form with valves on the left.

Much the same outward appearance on a larger scale is given the new six, which like the four has a Northway motor. The cylinder dimensions of both are 3 1-2 by 5 inches and practically the same general lines of design are adhered to throughout in both machines. They use the combination Delco cranking, lighting and ignition unit, unit power plants, left drive and center control, floating axles, three-speed gearsets and drive through torsion tubes.

PATERSON FEATURES

Four-Cylinder Model $1,095		Six-Cylinder Model $1,495	
Redesigned Motor	3½ by 5	Motor Size	3½ by 5

Rear Axle	Floating	Rear Axle	Floating
Starting and Lighting,	Electric	Starting and Lighting,	Electric
Gearbox	Three-Speed	Gearbox	Three-Speed
Fuel Feed	Gravity	Fuel Feed	Vacuum

Four-Cylinder Car Features

TAKING up first the design of the four-cylinder motor in detail, the detachable cylinder head is in one piece and is held in place by a number of specially heat-treated steel bolts with a copper gasket interposed between head plate and cylinder block to make a tight joint. The cylinders and the upper part of the crankcase are cast together, whereas the lower part of the crankcase, with which the oil reservoir is cast as a unit, is made of aluminum. The standard method of supporting a unit power plant in the frame is adhered to in that the two rear supports are integral with that part of the crankcase housing the flywheel and extend to the side rails, whereas the front center of the case rests upon a frame cross member.

Although this motor is the same in dimensions as that used last year, having a displacement of 192.4 cubic inches, it is so designed as to give more power due to a greater maximum speed, to lightening the reciprocating parts and to increasing the clear opening of the valve from 1 9-16 to 1 5-8 inch. The S. A. E. horsepower rating is 19.6. On the block it delivers as 37 horsepower when operating at 2500 r.p.m. This is quite high speed as compared with average domestic practice.

Modern practice prevails throughout this Northway design. There is no alteration in the three-bearing crankshaft over last year, but the pistons have been crowned which gives them maximum strength along with light weight. The pistons are fitted with nine thin carbon steel rings each, three to each ring slot. This is a growing tendency and has the advantage of making the leakage of gases past the pistons more difficult than with the older method of using three large rings. The gases must go past nine ring joints to escape instead of three, and further, the rings soon lap themselves into the cylinders due to the small wearing surfaces.

Drop-forged connecting rods have strap ends bolted in place. The camshaft is a drop forging with integral cams and is carried on three bearings. Spiral timing gears drive the camshaft as well as the pump shaft on the right side.

Tungsten Alloy Valves

The valves are constructed of the latest alloy which is said to be proof against pitting. It is a tungsten steel composition which has the property of remaining hard at high temperatures. The valves and springs are well covered by two plates, and breathing from the crankcase is by the vents in these covers so that there is communication through the tappets from within the engine to the outside air.

The motor is fitted with a Stromberg carbureter attaching to a two-branch manifold coupling to the cylinder openings below the exhaust header. The feed is by gravity.

Constant-level splash lubrication has the oil pumped from the reservoir into the crankcase by a small plunger pump operated by the camshaft. The amount of oil pumped is regulated by an adjustment which controls the stroke of the pump. After reaching the crankcase, the lubricant is distributed equally from basin to basin by small troughs cast on the inner side of the oil pan, which troughs run down from one basin to another. The troughs receive a part of the oil splashed up by the dipping of the rod ends into the basin, so that the system is of a distributing type which keeps the oil level constant in all the basins regardless of the angle of the engine.

Cooling is by centrifugal pump driven by a shaft on the right. It delivers the water into the center of the jacket, and the design of the water connections is such that free flow is allowed to go on unhampered.

Delco Unit Employed

Back of the water pump and driven by the same shaft is the Delco combination electrical unit which takes care of all electrical functions of lighting, cranking and ignition. The ignition distributor is vertical and in unit with the motor-generator proper. This Delco apparatus is the latest model and is much improved over its predecessors. The principal change is the current control which is connected with an automatic spark advance arrangement—another new feature. This current controlling device is purely a mechanical affair and consists of an arm wiping a brush over a coil wound so as to cause maximum current output at low car speeds. The main advantage gained is that when the car is running at average low speeds of from 10 to 15 miles an hour, the battery is being properly charged. As to the automatic spark advance, this consists of a centrifugal form of governor which automatically advances the spark when the speed of the engine increases within a certain range of the position of the hand spark lever on the steering wheel.

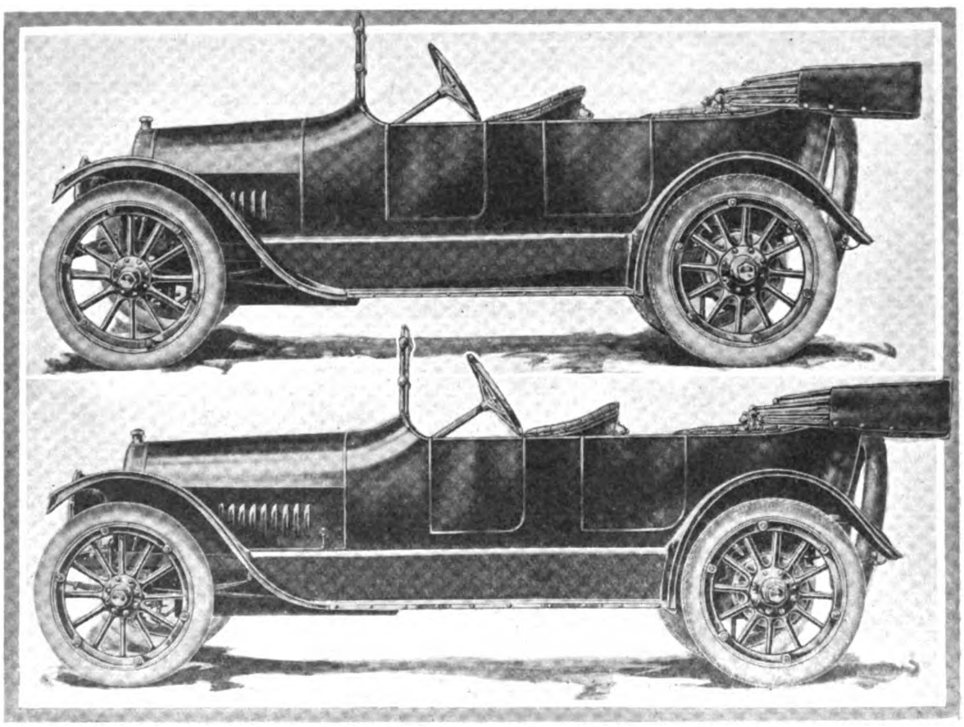
The familiar gear connection to the teeth in the flywheel face is used for cranking, the motor-generator then being temporarily and automatically transformed into an electric motor. The gear train which shifts into mesh with the flywheel teeth is completely and compactly housed within a case which is integral with the flywheel housing at the right rear supporting arm. For performing starting duty, the operator presses a pedal, which meshes the gears and sends current from the storage battery to the unit. When not used for starting, none of these gears is in mesh which saves wear as well as eliminates noise. The reduction in these gears is about 25 to 1, that is, the electric motor works about 25 times as fast as the crankshaft.

The system is of the 6-volt, single-wire type and the battery is mounted on the right side of the gearbox, between it and the frame.

Inclosed Cone Clutch

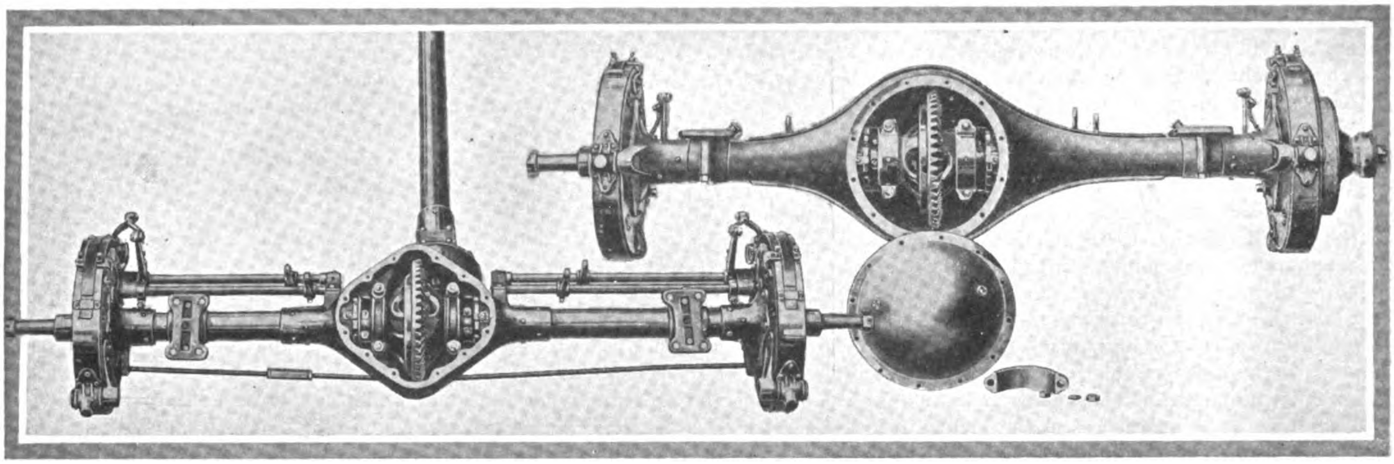
The bell housing at the front of the gearbox bolts to the flywheel housing, so that the cone clutch is completely inclosed. This clutch is faced with leather and easy engagement is provided for by the placing of springs under the leather. There are six of these springs.

The gearset a standard three-speed type has shafts and



Above—Four-cylinder Paterson for 1915, which sells for $1,095 fully equipped and fitted with Delco electric starting, lighting and ignition system. Tires are straight-sided, 33 by 4. Fuel feed is by gravity. The car has a new Northway motor, 3 1-2 by 5, and the only chassis change is the introduction of a floating rear axle

Below—Six-cylinder Paterson, listed at $1,495 with complete equipment. This car uses a motor similar in design to that in the four and with the same bore and stroke. Three-speed selective gearsets are used in both models. Tires on the six are 34 by 4. Fuel feed is by the Stewart vacuum system



Left—New floating rear axle used in Paterson four-cylinder model with cover plate removed. Note inclosed propeller shaft and arrangement of brake rods. Right—Floating axle used in the six-cylinder

gears made of nickel alloy steel, heat-treated and tempered. The gear ratios are: Intermediate, 1.76 to 1; low, 3.36 to 1; reverse, 4.32 to 1. Center control is not changed, the gear-shifting lever and the emergency brake lever bolting as an assembly to the rear of the gearcase.

The drive back of the gearset is not changed. The peculiar torsion tube construction surrounding the propeller shaft is very efficient. The front end of the tube houses a thrust bearing on the drive shaft. Thus the drive is taken by this bearing.

Practically the only chassis change is the substitution of a floating axle of demountable type in place of semi-floating construction. This axle is fitted with a cast housing of compact design. Wheels and differential run on Hyatt roller bearings, and New Departure ball bearings are used to support the pinion shaft. The axle shafts and gears are of nickel steel, and due to the floating construction, axle main shafts, differential gears and bevels may be removed without disassembling the housing.

Internal and external brakes acting on the rear wheel drums are fitted. Springs are three-quarter elliptic in the rear with scroll ends. The frame is pressed from 3-16 inch stock, of bottle-neck design and there is a rear kick-up to take care of axle movement. Standard 56 inch tread is used.

The Six-Cylinder Model

THE Northway six-cylinder motor used is practically the same in design as that already described. The cylinders are in a block, but instead of using a single detachable cylinder head plate, there are three of these, each covering two cylinders. Of unit power plant form, the engine is very compactly arranged, and in it practically the same improvements are found as in the four.

The S. A. E. rating is 29.5 horsepower. With the same dimensions as the four, it has a displacement of 288.6 cubic inches.

The casting of upper half of crankcase with cylinder block, the use of nine thin steel rings per piston, and the fitting of the same Delco unit as the four carries are proofs of the standardization which the Paterson company has adhered to. The Stromberg carbureter is used.

Like the four the six has cone clutch, three-speed selective gearset and inclosure of the propeller shaft within a torsion tube with the same distinctive thrust bearing design. The rear axle is somewhat different from the new axle of the four. The six axle uses a pressed-steel housing and Hyatt and New Departure bearings as in the other. The reinforcements of the housing make it extremely rigid.

Stewart Vacuum Feed

The Stewart vacuum system of fuel feed is fitted to the six only. The tank is mounted on the end of the exhaust manifold and high enough to give gravity feed to the carbureter. This vacuum tank is of standard Stewart make, drawing the fuel by suction from the supply tank into its upper portion and then allowing it to flow into the lower part as needed, the latter part being open to the atmosphere. From this lower part it flows to the carbureter.

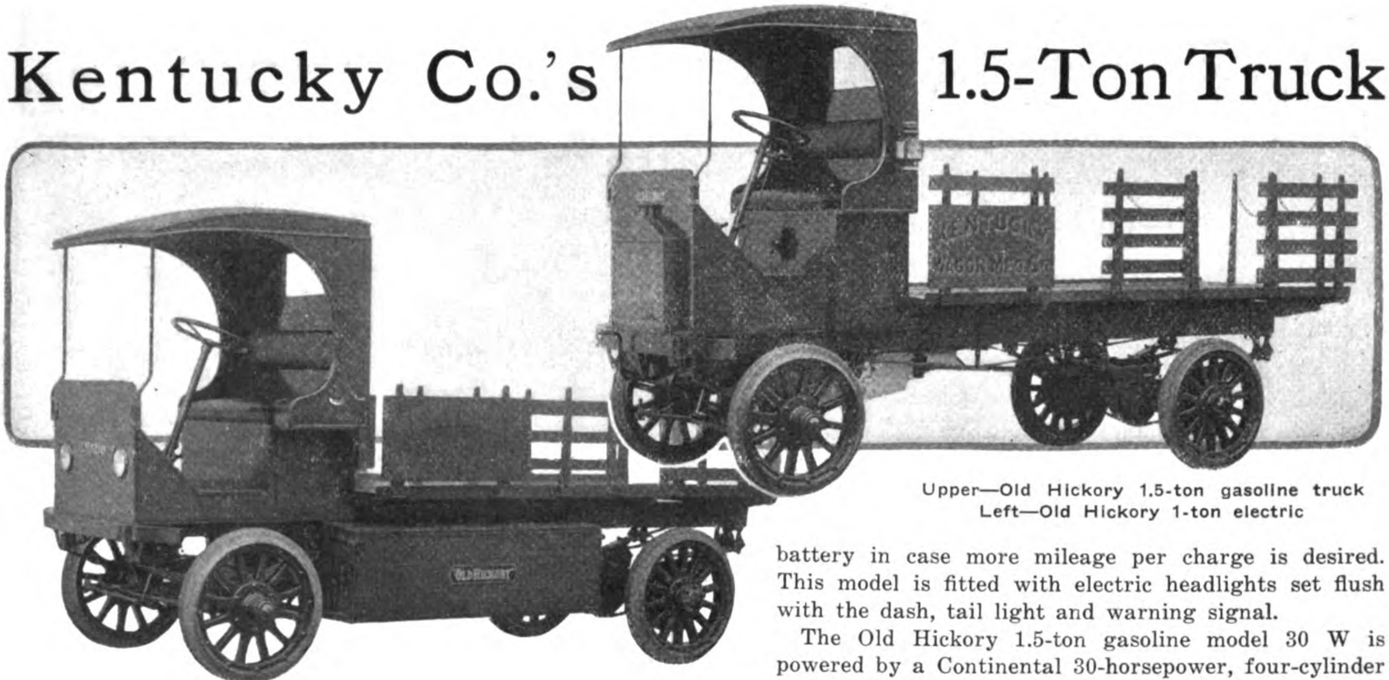
Kentucky Co.'s 1.5-Ton Truck



Upper—Old Hickory 1.5-ton gasoline truck
Left—Old Hickory 1-ton electric

Also Announces 1-Ton Electric—Known as Old Hickory Models—This Marks Entrance Into Gasoline Field

TWO new models have been announced for 1915 by the Kentucky Wagon Works, Louisville, Ky. One of these is a 1.5-ton gasoline model, a departure for this company which heretofore has made electric trucks only; the other is a 1-ton electric. These two models use the one running gear. With the four carried over from last year, this makes a total of six models for the coming season. The two new models are to be known as Old Hickory, and they are to sell for $2,000 complete with stake body and cab for the driver.

The models carried over and their prices are as follows: 1,500-pound, $1,500; 1.5-ton, $1,900; 2.5-ton, $2,500, and 4-ton, $3,000.

A departure from previous practice is noted in the use of worm drive which is employed on both the new models.

The Timken, David Brown gear drive is used and Timken roller bearings support the worm and worm gear while the rear wheels revolve on the same type of bearings on a floating rear axle.

The steering wheel is on the left side on both models with control lever on the electric car and gear shift lever on the gas car at the left hand.

Battery Capacity for 45 Miles

The Old Hickory electric 1-ton model 20W is fitted with a battery of ample capacity to drive the machine 40 to 45 miles to a charge. The battery is carried on a steel sub-frame on each side and by removing the side covers all battery cells are accessible so that the gravity of the electrolyte can be taken without disconnecting the wires or removing the cells. The electric motor is suspended well forward between the battery compartments and is connected to the worm shaft, a propeller shaft equipped with two universals. This shaft is in a direct line with the motor and worm shaft when the truck is loaded.

The controller giving the various speeds forward and reverse is under the seat connected directly to the control lever and is readily accessible by removing the seat panel. The balance of the space under the seat may be used for extra battery in case more mileage per charge is desired. This model is fitted with electric headlights set flush with the dash, tail light and warning signal.

The Old Hickory 1.5-ton gasoline model 30 W is powered by a Continental 30-horsepower, four-cylinder motor with sliding gearset in one unit. It is equipped with an integral circulating oiling system and with both battery and magneto ignition, the Heinze dual system being used.

An enclosed cone clutch transmits the power to the gearset which is mounted on roller bearings and gives three speeds ahead. The gear shift lever is at the driver's left.

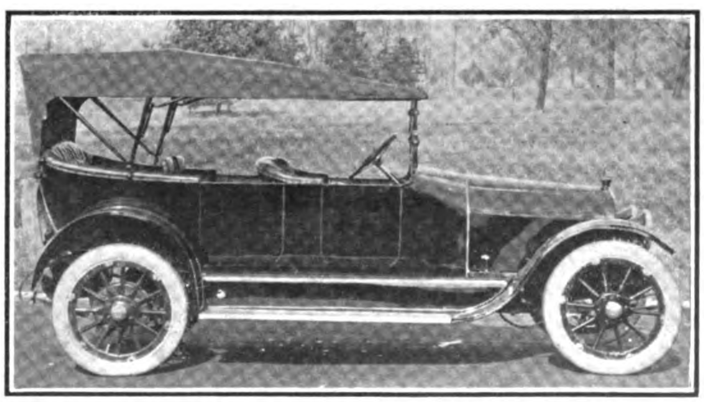
Clutch Operates Emergency Brake

The clutch pedal operates the emergency brake if operated with the service brake or while the service brake is applied. The gasoline tank is under the seat and feeds by gravity through a short copper pipe to the Holley one adjustment carbureter.

The Old Hickory Model 30W gasoline truck is fitted with oil side lamps, tail lamp and horn.

The double set of brakes are both directly on the wheel drums. Both the service and emergency brakes are operated by pedals and are fitted with equalizers.

To give added strength without detracting from its flexibility all frames are trussed on each side in exactly the same way as a railroad car. The springs are long, broad and flat, no troublesome shackles being used. The bronze wearing plates at the rear end of the springs, allow the necessary movement and also act as shock absorbers, deadening the rebound on rough roads.



The Moon model 6-40 at $1,575 is now being built in six-passenger type, as illustrated. To accomplish this, the wheelbase has been lengthened to 122 inches, and the frame increased in size, and notwithstanding this, the weight of the six-passenger is identically the same as the five-passenger, namely, 2,950 pounds. Model 6-40 is equipped with a 3½ by 5 six-cylinder Continental motor, unit power plant, Delco starting and lighting system, etc.

Vacuum Air Valve in Browne Carbureter

Position of Air Valve Determined by Vacuum at Nozzle —One Size for All Motors

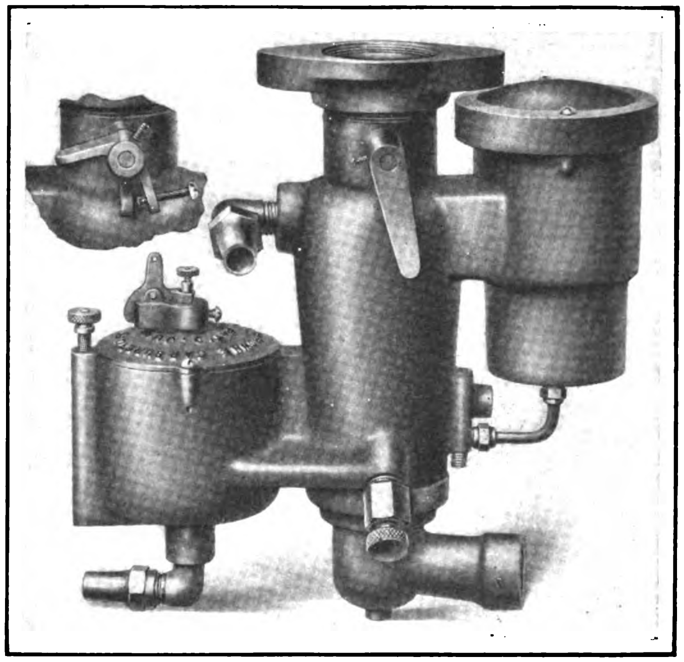
THE feature of the new Browne carbureter, for which the Holt-Welles Co., 1790 Broadway, is the selling agent, is the vacuum-controlled, auxiliary air valve by which, it is stated that a constant ratio between the fuel and the air is maintained at all speeds and throttle openings.

One Size for All Motors

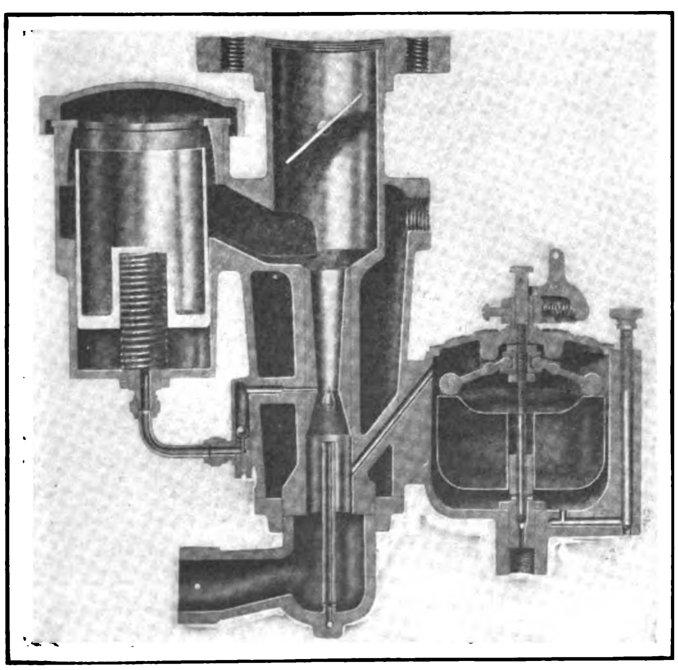
Only one size of carbureter is manufactured for all motors, and the only change for different motors is to put in a new bushing which surrounds the auxiliary air valve, and controls the area of the auxiliary air opening. Large motors use bushings with more sharply outcurving surfaces than small motors.

The same venturi construction is used regardless of the motor size. The throat area is small, insuring sufficient velocities to atomize the fuel at even the lowest speeds, it is stated. Friction at this point is reduced by giving the venturi a 30-degree approach and a 7-degree discharge.

The main air inlet is at the bottom whence the air passes up through the venturi where it mixes with the gasoline. Additional air is supplied by the auxiliary air valve at the left. This valve is an aluminum piston whose position is determined by the amount of vacuum in the chamber under it. This chamber is connected with the venturi, the opening of the passage being at the same point as the spray nozzle. The result is that the vacuum acting on the fuel and on the piston valve is exactly the same, and for a definite amount of vacuum, the valve must assume a definite position, therefore, for a certain rate of fuel flow, which is determined by the vacuum, the valve must take a certain position. There is a bushing, as previously noted, with a curved surface which surrounds the upper edge of this valve so that as the opening of the valve increases the area through which the auxiliary air may flow becomes greater. The curve of this surface is so calculated that for a given position of the valve, as determined by the vacuum at the spray nozzle, the amount of air to give a correctly proportioned mixture is obtained. For a wider throttle opening the vacuum increases, the rate of fuel flow becomes greater, and the valve takes a new position. Due to the curved surface of the bushing the new area of the auxiliary valve allows enough added air to give a perfect mixture, for this throttle opening, it is stated.



Exterior of Browne carbureter showing arrangement of parts



Section through Browne carbureter. The auxiliary valve is at the left. Note the dashpot control

Fluttering Prevented

Fluttering is prevented by means of a small ball which is held slightly off of its seat in the passage leading from the throat of the venturi to the air valve. When the air valve is depressed the ball offers no resistance but when the valve attempts to close a certain resistance is interposed to prevent fluttering. This arrangement also serves another purpose. When the throttle is suddenly closed there is a tendency for the fuel to keep on flowing at the same rate due to inertia. Were the air valve to close as suddenly the mixture would become too rich. The air valve is, however, retarded by the ball in the same proportion as the fuel flow is continued, thus maintaining constancy of mixture during this period.

A hot waterjacket is fitted and the main air inlet is finished so that a hot air pipe may be attached.

Easy to Get At

Accessibility is a feature. The carbureter may be taken entirely apart without removing it from the motor. The auxiliary valve may be lifted out after the dust cap is removed. The float mechanism may be inspected or removed after taking off the cover to the float chamber. Dirt from the seat of the float valve may be dislodged by means of the milled head on the upper end. The fuel nozzle may be cleaned by unscrewing and withdrawing the needle valve and inserting a piece of fine wire or a hat pin. The float chamber may be drained by loosening the needle valve at the extreme right of the sectional view.

Priming of the carbureter for starting is accomplished by pulling the priming lever on the top of the float chamber. This raises the needle valve and allows gasoline to flow into the float chamber until the level has raised sufficiently so that fuel runs down the diagonal passage into the main air passage.

New Stromberg Has Dashpot Type Control

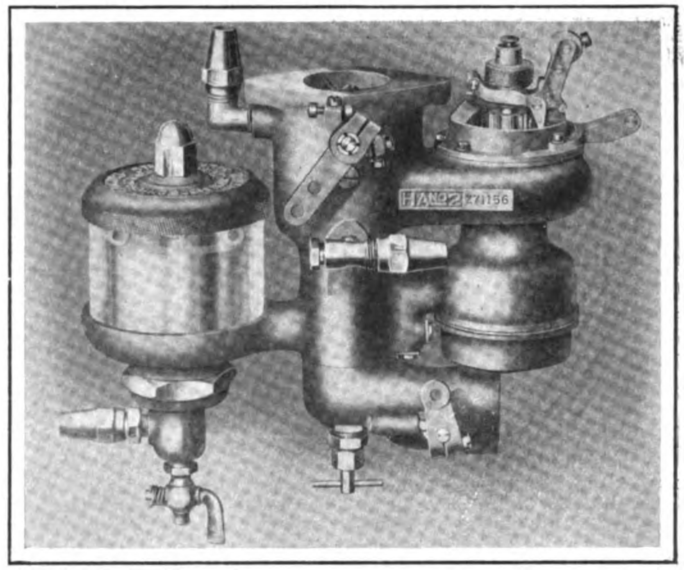
Secondary Jet and Air Valve Regulated by Dashpot— Horizontal and Vertical Flow Types

THE Stromberg Motor Devices Co., Chicago, Ill., has brought out a new type of carbureter embodying the dashpot principle in the control of the secondary fuel jet and air valve. This carbureter appears in three forms all of which adhere to former Stromberg practice of using separate low and high-speed functions, the former being by a set nozzle and the latter by the expanding carbureter portion of new construction. The three models are the H, a vertical type unwaterjacketed, the HA the same carbureter with waterjackets and the HB the horizontal type unwaterjacketed. The latter is exactly like the H with the exception that the mixing chamber is horizontal instead of vertical.

In the new Strombergs the motor is fed the proper mixture below 25 miles per hour from the low-speed jet with air from the primary intake and above that speed the auxiliary air valves come into action and with it the secondary nozzle, which is interconnected with the air valve.

When the car is running less than 25 miles per hour the low-speed nozzle only feeds the fuel and above that speed the dashpot comes into play. The piston shown is .01 inch smaller than its chamber and the fuel entering must work its way around the piston. Integral with the piston is a sleeve to which is attached the air valve. Within the sleeve is the secondary needle, which rests upon a seat shown and has at its upper end a button. The spring within the sleeve holds the needle in position. Should the air valve open, it carries with it the needle and at the same time forces the piston downward against gasoline pressure. However, the needle travels only through the distance AB. This is true because movement downward of the air valve carries the needle but, as soon as the button strikes the nut B, it will stop. While the needle is held stationary the valve may continue to move and so move the seat away from the valve.

In action the piston compensates for lag in the fuel. That is when the throttle is opened the air valve is not allowed to open quickly and thus cause poor carbureter action but instead acts against the fuel in the chamber and opens slowly.

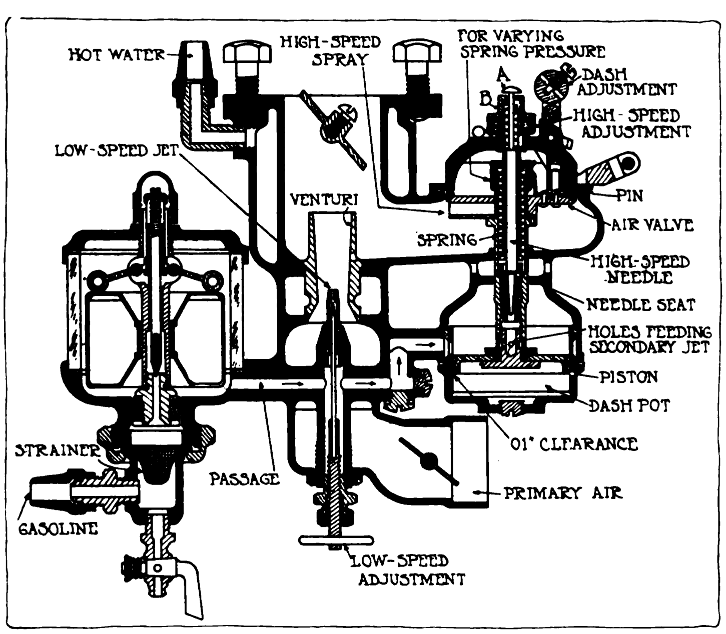


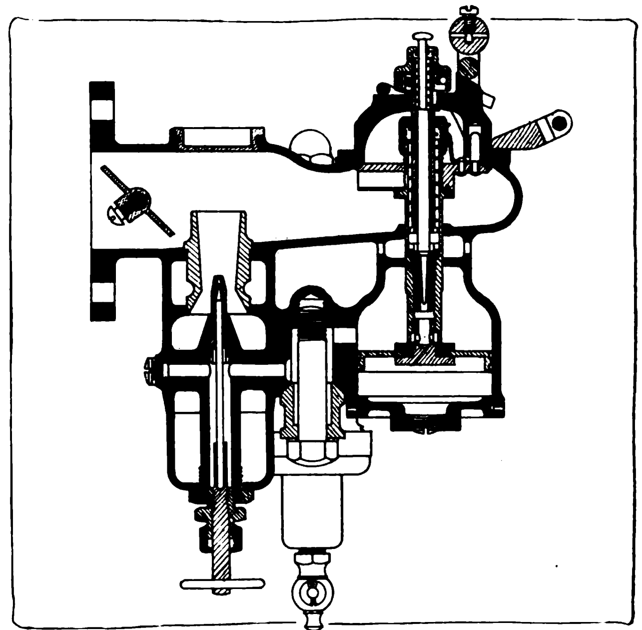
Exterior of Stromberg model HA, with dashpot control

When the fuel is in the chamber and the secondary air valve is opened by increased suction, fuel makes its way up through the holes at the top of the piston and thence through the sleeve to the tube integral with the air valve. The fuel leaving this tube is carried away with inrushing auxiliary air and forms the high-speed mixture. One important feature of this carbureter is right in this construction which prevents the secondary fuel spray from touching any metal as it leaves the tube and also getting better mixing by having the fuel meet the air which is at high velocity.

The primary nozzle adjustment is in the form of the handle shown and the secondary by means of the knurled nut at the top of the air valve. The dash adjustment, a series of levers, not only lifts the secondary needle from its seat but also locks the auxiliary air valve, so that on starting the engine gets a good mixture with the air supply shut off entirely, provided the primary air intake is closed by the butterfly valve.

In these new Strombergs the glass chamber and float construction are practically unaltered.





Left—Stromberg vertical type with the different parts designated. Right—Horizontal type, similar except for position of flange

From Report to Reality

SIXTY miles per hour in a stock touring car, with top and windshield up and with a load of five passengers, is no longer confined to the realm of conjecture or salesman's arguments but has become an official reality, by the Marmon speedway test in which a registered stock car traveled over 62 miles in the hour on the brick speedway. This performance is the best attribute to progress in automobile engineering in America and is one of the most applicable answers to those critics who ask, "How permanent has been the progress of the last 5 years?"

It is scarcely that long ago that a prize was offered for stock touring cars with load and windshield up that could travel a mile in 60 seconds going one direction on the speedway or road and then travel in the opposite direction and make 60-mile-an-hour pace for a distance of 1 mile. The makes of cars then foremost in the racing world tried but made signal failures. Today, while but one make has officially performed the feat of not only going 1 mile but 60 at a sustained speed, there are doubtless several other makes that could show a sustained speed of over 60 miles per hour.

Sustained speeds of this rate show that improvements have been at work in many parts of the car in lightening, balancing, tires, etc.

The Reward of Genius

FORD'S annual statement for the last fiscal year showing an increase in the surplus during the 12 months of more than $20,000,000, and a total surplus of over $48,000,000, is epochal. Never before in the motor industry has such a balance sheet been revealed, and very rarely in industrial lines is it exceeded, save by a few of the large corporations.

This annual statement coming from an industry not more than 15 years old partakes of the nature of a prodigy, a condition considered impossible 5 years ago in the automobile industry by the most sanguine.

Most phenomenal in connection with this statement is that such enormous profits are the outcome of production facilitated to the final syllable of perfection. Ford proved, as his year's progress shows, that perfected production methods do not necessarily mean greater physical and mental strain on the workmen, but rather the elimination of the un-essential, the un-necessary. His factory assembly method has been renovated, and by his new system of locomotive assembly, the endless-chain system, the workman is relieved of every possible burden, and is left free to confine his efforts to useful productive work.

That such profits and such a continued growth can come from the manufacture of so cheap a car but once more indicates the lines along which genius so often travels. It again demonstrates the strength of the masses as opposed to that of the classes. When Henry Ford first presented his four-cylinder car at the show in New York, in response to the object he had in designing a cheap car the answer came, "I have set out to build a car good enough for an American to ride in."

Here is the reward of genius and consistent endeavor. Genius mapped out a field undreamed of by others; and annual balance sheets disclose the reward.

The Maelstrom

IT is to be hoped that the floating axle patent litigation which has at last been started will not permeate the entire industry and while it will not have any deterrent effect on the purchasing powers of the country. It is bound to create more or less division in the industry as well as unrest among the many companies that own patents, that they believe to be valid and which they could bring out of their strong boxes and use to the discomfiture of other makers, if they so desired.

The unfortunnate aspect of patent litigation is that so much money and energy are expended in this work that could be expended in improving production methods. Ford estimates his patent assets at a few thousand dollars and yet his annual statement shows a profit of over $20,000,000. Production with him has been more valuable than patents.

There are more than 1,000 different patents referring to the automobile that are owned or controlled by the car and accessory makers. What if suits were brought on all these?

Road Congress Ends Big Session

Over 3,000 Delegates, Representing Every State in Union, Demand Federal Aid in Trunk Line Building

By J. C. Burton
Staff Correspondent

ATLANTA, GA., November 14—"Uncle Sam, Road Maker" reads the sign that soon will be dusted off and nailed to one of the white pillars of the national capitol at Washington.

This is the prediction emanating from the fourth American road congress which closed the most successful session in its history here today. More than 3,000 proponents of highway improvement, representing every state in the union, are the authors of such a prophecy. They also will be prominent agents in its fulfillment. They have called upon the federal government to act and to act immediately. They have demanded the passage of a bill in congress that will provide for federal aid in the construction of main trunk lines throughout the United States.

Within the past 6 days, the American road congress has developed a backbone. For the first time in the history of the organization, it has made demands, definite demands, and back of these demands is a determination to push them until they are complied with. The polite verbiage in which the demands are clothed is but a kid glove over a mailed fist. Legislators, who pay no heed to the recommendations of the road congress, probably will find that out very soon.

Federal Aid for Main Routes

Federal aid in highway construction was the keynote of the 1914 congress. Monday's session, in charge of the American Automobile Assn., was devoted entirely to the subject of national legislation and the two principal speakers of the day, Senator Hoke Smith of Georgia and Representative W. P. Borland of Kansas, each promised to work for the passage of a bill that would make federal appropriations for highway construction possible. The resolutions committee, the official mouthpiece of the congress, gave the subject of federal aid the place of prominence on its list of recommendations, the resolution reading as follows:

"Resolved: That the American road congress emphatically endorse the principle of federal co-operation toward the construction of main highways and thus assist the several states to build the main market roads on the one-half of country devoted to agriculture and to build through main roads in the one-half of country which is not predominately agricultural but whose prosperity depends upon mining, the raising of live stock and the presence of the healthseeker and tourist."

"Federal aid for roads and not for the pork barrel" was the slogan of the congress. One delegate, President Kenyon of the Indiana Good Roads Assn. expressed the sentiment of the 3,000 and more proponents of highway improvement in attendance when he declared, "Shake your fist under the nose of your congressman and tell him that if he is not in favor of federal aid, you are not in favor of him."

Commission to Spend Money

The plan which the federal government should pursue in aiding road construction, as generally outlined by the dozen or more speakers who addressed Monday's session of the congress, is to have whatever funds congress might appropriate placed in the hands of a competent commission, which shall select the locations for the expenditure of the money. It was argued that to appropriate good roads money in "pork barrel" fashion, as much as it would boost the stock of individual congressmen back home, would result in little practical or lasting improvement of the highways. Such a procedure would merely smear an insufficient fund thinly over a large territory.

It is the belief, however, that the commission empowered to dispense the fund should place the money only after a most careful study of conditions in each and every state. Thus trunk roads would be built where they are most badly needed and most used. The plan of the road congress is that the states and not the national government shall bear the expense of the general upkeep of the highways and it is further contemplated that the states through which federal aid roads are to be built shall appropriate proportionate amounts for the construction of feeder roads.

Money for Main Routes

Representative Borland of Missouri, who led the successful fight on the Shackleford post roads bill in congress last year, was the champion of the American road congress' plan for federal aid.

"I will not vote for a bill which spreads money over a large territory," he declared. "I want the money centered on some special mileage where it can do some real good whether a cent of it is spent in my county or not. We want a system of roads that will open our country up, but in their construction, we've got to follow a system. First, build the main trunk roads; then the provincial or county roads; after that the little by-roads will come.

"Building wagon roads is like building railroads. The railroads build their main trunk lines first, not their switches and small feeders. But there are congressmen and senators in Washington who in our highway construction would have us reverse the system of railroad building.

"The big highways cannot be consistently built and maintained by local districts. We must have a general and special fund for this with proper supervision of its distribution. The smaller roads are legitimate objects for local operations. We can't have a blanket law to build 250,000 miles of road. We have got to start somewhere on some specific road. We have got to realize that. It is folly to think that we can accomplish anything any other way.

"There is no division of interest between city and country on the point of good roads. The business of the country is the foundation for the business of the city. The national government should build highways through Georgia and Kansas for the same reason as it appropriates millions for the improvement of harbors of the ocean shipping points. It is just as important to get the cotton or wheat to the port as from the port."

The American road congress will fight any measure introduced in congress that does not provide for the appropriation of money for main trunk lines, roads that will rival the national routes of France, the imperial highways of Germany and the inter-county roads of England. In the past 3 years, 140 bills, providing for the use of federal funds for highway construction, have been introduced in House and Senate. Not one passed. They were too limited in scope or impractical, the majority of the measures carrying appropriations for the construction of special or insignificant roads. Of such a type was the Shackleford post road bill of the last session of congress, a measure that if passed would have spread $25,000,000 over a vast amount of territory and resulted, it is claimed, in the temporary building of highways largely in isolated districts.

New National Organization

The delegates to the congress are confident that such a federal aid bill will be passed. In order that all the forty-eight states will be in a position to enjoy the benefits accruing from such a bill when it finally is passed, the state highway officials in attendance formed a national association on Thursday. One of the chief aims of this organization will be to bring the building of roads under the supervision of state officials in the eight states that have no state highway departments—Georgia, Indiana, North Carolina, South Carolina, Tennessee, Arkansas, Florida and Texas. It is the belief that the federal aid bill will provide for the disbursement of the fund and the construction of the roads by the several state highway departments and unless these eight states obtain state highway departments, they will be ineligible to share in the national benevolence.

The national association of state highway officials will hold a meeting in Washington, D. C., December 12, when the organization will be perfected, officers elected and a bill, embodying a plan for federal co-operation in road construction and to be presented to congress, will be drafted. The new association also will attempt to make all state highways uniform.

Besides stating definitely the stand of the American road congress on the question of federal aid, the resolutions committee, in its report, made several other important recommendations. It urged the formation of state highway departments in all states as essential to secure efficiency and economy in the construction and maintenance of roads, commended the Lincoln Highway Association for its voluntary efforts in building a transcontinental route from the Atlantic to the Pacific, deplored the frequent number of accidents on the highways and asked the authorities to enact necessary rules and regulations to insure the public safety, and called upon the government to build highways across all Indian and forest reservations and all other federalized areas.

For the past 6 days, Atlanta has been a great clearing house for the exchange of sound, sane, practical ideas on highway construction, improvement and maintenance. Since Monday, the city from which Sherman marched to the sea 50 years ago, has been a vortex of good roads enthusiasm. The attendance at the 1914 congress broke all records. More than 3000 delegates registered. Morover, it was a most representative meeting. Men from the North and South, men from the East and West, came here to teach and learn. Each of the forty-eight states in the American sisterhood sent state, county, township, commissioners and engineers and good roads proponents to the congress. On the eve of the general exodus from Atlanta, the feeling prevails that an epochal chapter in the history of American highway development was written at Atlanta.

Dixie's Great Chance

Fortunate indeed was the selection of Atlanta as the 1914 meeting place. The south is a most fertile field for the sowing of the good roads seed and during the past week, the army of delegates to the convention have scattered it far and wide with the result that Dixie eventually should harvest a crop of highways as valuable as its more famous cotton crop. Moreover, Atlanta and Fulton county are excellent laboratories in which can be seen the results of good roads experiments. Atlanta can boast of municipal street improvements that are the equal of any in the other metropolises and the county roads in the vicinity of the city are model types, rivaling the noted highways of Wayne county, Michigan and Milwaukee county, Wisconsin.

The delegates also had an opportunity to study the results of the convict road system at first hand and at its original source, for Georgia took the initiative in the movement to employ its prisoners on the highways, a movement that has spread rapidly within the last decade until now it has no geographical bounds.

Varied Program

The program for the fourth American road congress was all-embracing in scope. Monday's session was devoted entirely to the all important subject of national legislation and federal aid. State legislation was the topic for Tuesday morning and the merit system in road administration was discussed by speakers at the afternoon session. Problems in construction and maintenance were considered Wednesday and Thursday's session was a sort of pot pourri in which several topics, including system in road management, street construction and maintenance, convict labor, road making by the army and contract work, were discussed.

Valuable as the addresses in the large Taft hall were, it was evident that the impromptu discussions of highway commissioners and engineers in the hotel lobbies and around the machinery and material exhibits were even of greater value. Here the man from Georgia learned of a system from the man from Michigan that would solve his road problems. The engineer from Indiana discovered that the engineer from California had used a particular grader or scarifier and found that it was both efficient and economical and that it would give as good service on Hoosier roads as it had on the highways of the Pacific coast.

Road Machinery Exhibit

There were a larger number of exhibitors of road machinery and materials at the Atlanta convention than at any of the previous meetings of the American road congress and the United States government and the state of New York had two notable exhibits that attracted a great deal of attention. Uncle Sam sent to Atlanta a series of road models—to be shown at the Panama-Pacific exposition—which showed the evolution of road building for 2,000 years and included the Appian Way of 300 B. C., the early French roads of Napoleon, the English macadam highways built during the reign of George IV and the several types of modern roads. Father Knickerbocker sent a replica in papier-mache of Old Storm King, the mountain along the Hudson where engineers of the Empire state are constructing a new trail, 2½ miles in length and with an average grade of 7 per cent., at a cost of more than $500,000.

The American Highway Association, which, with the American Automobile Association, forms the American road congress, held its annual meeting Thursday evening when the following officers for 1915 were nominated: President, Fairfax Harrison of Virginia, president of the Southern railroad; vice-president, Logan Waller Page of Washington, D. C.; treasurer, Lee McClung of Washington, D. C., former treasurer of the United States. The following directors were nominated for a term of 3 years: A. G. Batchelder, New Jersey; Bryan Lathrop, Illinois; Leonard Tufts, South Carolina; W. Tom Winn, Georgia; C. E. Blaney, California; W. D. Sohier, Massachusetts, and S. E. Bradt, Illinois. These officers and directors will be formally elected at a meeting of the executive committee to be held soon.

At the annual meeting of the congress several cities put in a bid for the 1915 meeting, but it is probable that the invitation of San Francisco will be accepted since such a selection will give the delegates an opportunity of visiting the Panama-Pacific exposition.

Shaw Motor Incorporates for $1,000,000

PRAIRIE DU SAC, WIS., Nov. 14—The Shaw Motor Co., Chicago, Ill., which recently selected Prairie du Sac, on the Wisconsin River, as the site for its permanent factory, has filed articles of incorporation and a statement to do business in Wisconsin as a foreign corporation. The capital stock is $1,000,000 and the Wisconsin interest is given at $30,000. Contracts were awarded late last week for the machine shop, office and assembling building, to be 60 x 108 feet in size, 19 feet high, with saw-tooth roof. In addition, the company has the use of the former Kahn foundry for producing its light castings. It is hoped to start operations by Feb. 1, 1915.

$1,000,000 Company to Make Tire Machine

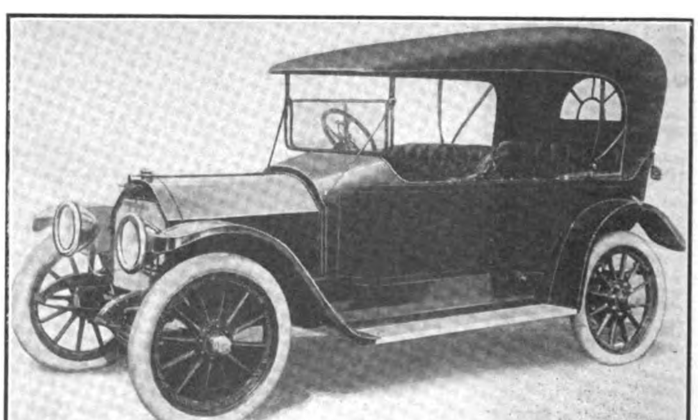
INDIANAPOLIS, IND., Nov. 14—The Dickinson Tire and Machine Co. has been organized and incorporated with an authorized capitalization of $1,000,000 at Indianapolis to manufacture a tire weaving machine invented by Fred S. Dickinson, of Bedford, Ind., and New York. The new machine will weave a tire in a solid piece, of the proper dimensions. The fabric will be woven bias to give maximum strength.

McIntyre Brings Out Six for $1,275

AUBURN, IND., Nov. 16—A six-cylinder car for $1,275 has been announced by the W. H. McIntyre Co., Auburn, Ind., for 1915. The car is fully equipped even to a one-man top. Power is produced by a six-cylinder 3.5 by 4.5 motor with cylinders cast in a block. The clutch and gearset are a unit with the motor. The clutch has twenty-one 10-inch disks and the gearset affords three speeds forward. The wheelbase is 120 inches and 35 by 4-inch tires with demountable rims are used.

LIMA, O., Nov. 16—The Willys-Overland Co. will manufacture at the Gramm plant in Lima only 1,350-pound delivery wagons. The force will be increased to an extent where five of the delivery wagons will be turned out daily.

John N. Willys, head of the company, recently deposited $100,000 in the Lima banks to take care of obligations against the Gramm plant, assumed when purchased from the former company several years ago. This was done in order to ease the money market of Lima.



New McIntyre six selling for $1,275 with full equipment, top, etc.

To Eliminate Non-Resident Registration?

Supreme Court Hears Arguments on Test Case—Washington Motorist vs. State of Maryland

WASHINGTON, D. C., Nov. 14—Is it legal for any state in the Union to require a motorist living in another state to take out a non-resident license for his car before driving in states in which he does not reside?

This question was brought up in July, 1910 by a Washington, D. C., motorist who was required to carry a Maryland license before he was allowed to drive his car in the state. The owner decided to make a test case of the matter and this case finally came before the Supreme Court of the country where it was argued last week. It is expected that a decision will be handed down in a couple of months. Should a favorable decision be received, motorists believe that the non-registration clause in all our states would be void and illegal.

Question Is Important

The test case is that of J. Tilghman Hendrick vs. the State of Maryland involving the question of whether or not Maryland has the constitutional right to impose a tax upon motor car owners in the District of Columbia who use the Maryland highways. In the argument for the Supreme Court this week, the validity of the tax was upheld by Attorney General Poe and Attorney Enos S. Stockbridge, while Hendrick's contention was presented by Osborne I. Yellott, counsel of the Automobile Club of Maryland and Jackson H. Ralston, of this city. The question is one of great interest to motorists throughout the country and the court's decision, which will be rendered within the next 2 months' will be anxiously awaited. Hendrick is a Washington man and refused to pay the tax in order to test the law. The main argument of his attorneys was that the Maryland act was a discrimination against the District of Columbia in favor of other states in that residents of other states in the union were not assessed for the license fee when they used the Maryland highways; whereas motor car owners of the District of Columbia are. They also contended that the act imposing a charge upon District motorists is a regulation of commerce beyond the jurisdiction of Maryland to impose. The Maryland law is a revenue act and not within that class of laws under which States are allowed to demand compensation for the use of works of public improvement. This follows, it was contended, since the tax on the District motor cars is imposed without regard to the extent of the use of the improvements. It was pointed out that there are 10,000 motor cars in Washington, 6,000 of which are barred from going into Maryland by the license tax.

Charge Big Salaries Are Purpose

Attorney Ralston also charged that the chief purpose of the tax on District motorists was to help pay big salaries to the members of the Maryland motor car commission. "The only reasonable purpose for which a District motorist using the roads of Maryland could be compelled to pay a tax," he declared, "would be that of affording proper police identification and should not in that case be more than $1. But instead of a logical fee of that sort, the charges on District motor cars run from $5 to $25. District motorists are obliged to pay not only an identification fee, but also for the enforcement of all the laws of Maryland roads affecting motor cars and the large salaries of the motor car commission, as well."

Not a Violation of Interstate Act

Attorney General Poe contended that the license tax was not a violation of the interstate commerce act on the grounds that "a state is justified in requiring those who elect to use on its highways a mode of travel that is abnormally destructive to that road to compensate it for such use. Let us direct attention to the results aimed at by this law," he continued, "bearing in mind that we are dealing with regulations of high-powered machines capable of causing great injury and destruction of life and property and a consequent difficulty of detection unless plainly and at all times distinctly marked. It is, of course, apparent that this law seeks to protect person and property by requiring the automobile to be registered, so that in case of damage and injury the owner may be located. All of these purposes are clearly within the police powers of the state and are among the primary objects of that power.

"What bearing does this, then, have on residents of the District? The court will take judicial notice of the geographical location of the District to the borders of Maryland; that the District contains a large and populous city; that it is limited in area and that therefore users of motor vehicles necessarily are forced to go frequently into the adjoining states. The court will also take judicial notice of the fact that there is no large city in any other state so situated with respect to the borders of Maryland."

Denies Right to Discriminate

Ralston denied the right of the state to discriminate against District motorists in favor of motorists who are residents of other states. He assured the court that there is nothing in the law to sustain the claim of Attorney General Poe that the state has the right to make a special discrimination against the District because of its proximity. He argued that such a premise is without valid foundation, as it includes all federal districts and territories.

Several questions relative to certain phases of the case were asked from the bench. The court particularly inquired about the charge that the law is a gross discrimination and why the District is put in the same class as Alaska.

Attorney General Poe's answer to these inquiries in general was made in an explanation that the District is of small area and having thousands of automobile owners who constantly make use of Maryland roads, the state is entitled to exact payment for the use of its highways and in the manner prescribed by the law now being attacked. He contended that the law is in keeping with former supreme court rulings bearing on similar cases.

The opening argument for Maryland was made by E. S. Stockbridge, who was followed by Attorney Yellott, for the District, who contended that it is the right of all citizens to go where they please by any proper means of transportation without being subjected to any tax. The argument extended over 2 days and was closely followed by the court.

Fight Anti-Glare Ordinances

PHILADELPHIA, PA., Nov. 7—Automobile headlights are prohibited in Fairmount Park after November 15, the Park Commissioners having issued an announcement to that effect. The question of the responsibility of car drivers in cases of accident caused by the use of only dim side lights has been raised by frequent users of the park drives, who, in opposing enforcement of the new regulation, claim that the dangers of collision will be more numerous than ever before. At a meeting of the Quaker City Motor Club in the Hotel Walton President Huyette appointed a committee to make observations at night in the various driveways in the park as to conditions existing along poorly lighted roadways, and have the data presented to the Park Commissioners with a view to having the order modified to permit searchlights on certain driveways as being necessary to the safety of the public.

SEATTLE, WASH., Nov. 14—Motor car owners of Seattle, backed by the Automobile Club of Seattle, have started a fight on the anti-dazzling headlight law recently put into effect in this city. The ordinance prohibits glaring headlights of any kind within the city limits, the district not being confined to the business section. As a result of the law a number of accidents have occurred in the residence districts.

DENVER, COL., Nov. 13—About 200 motorists have been summoned into police court during the last week to explain their failure to meet the requirements of the new law prohibiting glaring headlights. Many others have been stopped and warned by the police.

ST. LOUIS, MO., Nov. 14—Joseph L. Norris, a chauffeur, was convicted of "felonious wounding" and sentenced to a year in the St. Louis Workhouse. This was the first conviction by a jury on the charge which became a local law about 2 years ago. Norris ran over and injured a 9-year-old boy 3 months ago, and witnesses testified he was driving his machine at about 25 miles an hour and that he did not sound an alarm. After striking the boy the car ran about 250 feet before Norris could bring it to a standstill.

Floating Axle Patents in Suit

Patent-Holding Company Alleges Car Maker Infringes—N. A. C. C. May Take Hand

CHICAGO, Nov. 11—Suit was begun here today in the United States district court before Judge Landis by the Kardo Co., Cleveland, against the Studebaker Corp., Detroit, alleging infringement by five patents which the Kardo Co. holds and which the suit alleges that the Studebaker cars infringe. The major patent in this suit is that of a floating axle construction, one of the patents which the Kardo organization controls. This patent was originally issued to Louis P. Mooers, and has been re-issued with some additional claims. It covers rear axle construction in which the drive shafts of the axle can be withdrawn and further in which the differential unit can be adjusted with reference to driving pinion on the rear of the propeller shaft.

It has been anticipated for some time that the Kardo company would sooner or later begin suit against some of the motor car manufacturers, although no information was given as to against what company the suit would be filed. Since its organization some months ago the Kardo company has made many overtures to car manufacturers with the apparent intention of having them take out licenses to build axles on a royalty basis. Up to this date none of the manufacturers have taken licenses. The license arrangements offered to some companies were on a royalty basis of $2.50 per car, this to cover the Kardo patents so far as referred to rear axle construction. This figure was reduced according to the quantities in which cars were to be manufactured.

Chamber of Commerce May Fight

It is anticipated that the National Automobile Chamber of Commerce will take up the fight of this patent against the Kardo company, although no official announcement has been made to this effect. The N. A. C. C. has, through its legal and patent departments, been conducting an exhaustive investigation on the Kardo patents, and it is expected that this report will be furnished soon. The N. A. C. C. has during its existence aimed at reducing patent litigation to the minimum, and with this object in view purchased for the protection of its members the cork insert patent governing the use of cork inserts in clutches and brakes, and more than 2 years ago purchased for the protection of its members privileges under the Dyer patents governing sliding gear transmissions in motor cars. Up to this time it appears that the Kardo company has not made any advances towards the national body with reference to the patents it controls.

The N. A. C. C. today issued the following official statement regarding the present suit against the Studebaker Corp.

Official Statement Issued

"Officials of the National Automobile Chamber of Commerce believe that makers as a unit are opposed to any effort on the part of the Kardo Co. to extract tribute from the automobile industry on the eight or nine patents which it has secured from inventors with a view solely to secure revenue and not with the thought of protecting its product.

"The N. A. C. C. has made a comprehensive search in preparation for any aggressive movement of the Kardo company and from expressions of the members and directors it would appear that the entire industry is united to support any of its members that are attacked and to defend them in every way. The ablest counsel has been retained for this purpose, including Frederick P. Fish, of Fish, Richardson, Herrick & Neave, Boston, Mass.

"There are ninety-three motor car makers in the N. A. C.C. who have looked with disfavor upon the incorporation and purposes of the Kardo company, which was formed as a patent-holding company of an offensive nature, with a view to demanding royalty from motor car builders, which counsel has declared are of doubtful validity, and the payment of any royalties on which would be of no benefit whatever to the inventors. At this stage of the industry, with manufacturers endeavoring to give as great value as possible in automobiles, they do not feel that an additional royalty charge against the public is desirable."

Readers of THE AUTOMOBILE will recall that the Kardo company was incorporated some months ago by representatives of three companies, the Peerless Motor Car Co., Cleveland, the American Ball Bearing Co., Cleveland, and the Packard Motor Car Co., Detroit.

The patents involved in the Studebaker suit are:

No. 705,304 to C. T. Brock Sangster, July, 1902.
No. 753,168 to Walter C. Baker, February, 1905.
No. 792,690 to Alanson P. Brush, June, 1905.
No. 832,991 to L. P. Mooers, October, 1906.
No. 1,013,450 to Chas. Schmidt, January, 1912.

Of these patents that of Louis P. Mooers was assigned to the Peerless company; that of Mr. Brush to the Baker Motor Vehicle Co., and that of Chas. Schmidt to the Packard company.

The present action claims that these are all infringed by the Studebaker Corp. It is supposed that the Studebaker case will be a test one, although there are no indications that the Kardo company may not begin suit against other manufacturers.

The most important patent of the group is the Mooers one, which provides for a floating axle construction, with removable axle drive shafts and adjustments between the differential driving member and the driving pinion on the propeller shaft.

The Schmidt patent refers to a rear axle type of gearset at present used by the Packard company.

The Brush patent relates to the mounting of the differential and driving pinion of the rear axle for adjustments.

The Baker patent refers to a bevel gear rear axle in which adjustments can be made in connection with the differential without opening the housing.

Hand Horn Claim Is Sustained

WASHINGTON, D. C., Nov. 14—A new factor was injected into the present patent litigation on hand-operated horn when the Board of Appeals in the Patent Office affirmed a decision made by the patent examiner that Emanuel Aufiero is entitled to his claims on the flywheel construction in hand-operated horns and that G. F. Long, who was granted a patent on this construction, is not. Mr. Aufiero is connected with the engineering department of the Automobile Supply Mfg. Co., to which company his patents belong. According to Patent Office procedure Mr. Long has until December 4 to take an appeal to the Commissioner of Patents in the case.

The flywheel construction in hand-operated horns refers to the use of a heavy flywheel which is started to rotate when the horn handle is operated. Once this flywheel is rotating it will continue for some time, due to its weight. The rotation of the flywheel accomplishes the vibration of the diaphragm.

In the present case Mr. Long was granted a patent, No. 1,090,080, last March, embodying this form of construction, but it now appears that the patent examiner has ruled that Aufiero's claims are valid and not Long's. Mr. Long's patent is assigned to the Gottfried Piel Co.

Bosch Denies Magneto Patent Infringement

NEW YORK CITY, Nov. 16—The Bosch Magneto Co. has filed its answer to the bill of complaint filed against it by the Splitdorf Electrical Co. charging infringement of patent No. 1,074,416, and denies infringement, averring that the patent in suit is invalid.

The Bosch company admits that the patent was duly issued to John M. Dinkins, Franklin B. Hays and William L. Taylor, all of Indianapolis, Ind., September 30, 1913, but denies that the patent is valid and that it was granted in accordance with the then existing statutes of the United States. It further denies that it has infringed or threatened to infringe said patent and that it has received any gains or profits by any infringement of the patent or that it has caused the plaintiff any damage. The defendant further claims that John M. Dinkins and Franklin B. Hays were not the original inventors of any material part of the thing patented, but that every part thereof was in use prior to the alleged invention or more than 2 years prior to the application for the patent. In proof of this assertion the defendant cites French patent No. 342,209 to Adolph Clement and Marcel Masson; French patent No. 357,769 to Rudolf Rickmann; German patent No. 170,055 to Josef Gawron; German patent No. 45,161 to Paul Winand, and *The Automotor Journal*, Vol. 12, No. 20, pages 667, 668 and 669.

Asserts Prior State of Art

The Bosch company also asserts that the state of the art of magneto ignition systems at or before the time of the alleged invention of the patent was such that there was nothing new or patentable in such an alleged invention and that, therefore, this invention was not patentable under the laws of the United States. The defendant declares that it is ready and willing to prove this state of the art. The Bosch company submits to the court that the plaintiff has no right to any further answer to its bill of complaint or any part thereof, and it prays for dismissal of the suit.

The patent in suit, No. 1,074,416, as stated in THE AUTOMOBILE for November 5, covers means in a magneto ignition system for changing the polarity of the armature to coincide with the polarity of an external current during the time that the primary winding on the armature is coupled with the external source of current. The object of this system is to use a battery and a coil in connection with the primary winding of the magneto to produce a sufficient current for ignition purposes for easy starting at low cranking speeds. This is commonly known as a duplex system.

The suit is brought in the United States district court for the southern district of New York.

Ford Increases Surplus by $20,702,859.39

Total Surplus Is Now $48,827,032.07—Liquid Assets Increase Over 100 Per Cent in Past Year—Cash on Hand $27,000,000

DETROIT, MICH., Nov. 13—The Ford Motor Co., during its fiscal year ending December 30, 1914, increased its surplus over $20,000,000, the actual figures being $20,702,-859.39. The company started its fiscal year with a surplus of $28,000,000, so that this added to the profits of the present year gives the company a present surplus of $48,827,-032.07.

During the year, the liquid assets of the company have increased more than 100 per cent, liquid assets being meant cash on hand and accounts receivable. A year ago the cash on hand was over $13,000,000, today it is over $27,000,000. Last year the accounts receivable were half a million, this year they are over $3,000,000, a fact no doubt explained by the great increase in the number of accounts during the past year.

Factory Values More Than Doubled

But during the year other aspects of the Ford business besides the liquid assets have shown enormous increases. Factory values have more than doubled. A year ago, the buildings and building fixtures were estimated close to $4,500,000. This year they are nearly $10,725,000. These figures are not exactly accurate, the actual ones being given on the balance sheet being reproduced herewith.

Looking at the real estate aspect of the company, it has shown a very healthy growth during the year, increasing from $1,500,000 to $2,225,000. The factory equipment has increased from a little over half a million to one and one-half million. The investment in machinery has risen from $2,000,000 to nearly $4,000,000.

The present surplus of nearly $49,000,000 is not only the biggest among all the automobile manufacturers of the world but one of the biggest among all industrial or manufacturing concerns in the United States. It is all the more conspicuous because during the past 9 months of the fiscal year the profit-sharing system of the factory has been in operation, 82.5 per cent. of the employees sharing in this plan.

When the vice-president of one of Detroit's oldest banks was asked to what he attributes the remarkable financial showing of the Ford company, he said, without allowing his name to be quoted: "Not only is the Ford company the most conspicuous automobile factory in the country, but it has one of the greatest business organizations in the world. To be able to make the showing it has just announced, when business conditions the world over have been none too good for many months and with the installation of the profit-sharing plan, which turns into the pockets of the employees a very important part of the profits, the company must have not only captains of industry but of finances, men such as there are few to be found in our days, who know how to run a big business end and not only from the manufacturing end. That is what is lacking in all industries; men with sound business judgment, men who will not risk, who will not take too big a chance and ruin a concern to fulfil their ambition. In the automobile business this has been in most cases the cause of many concerns going to the wall."

Big Success on Specialization

Although the Ford Motor Co. started in business in June, 1903, it is only since 1908, when the policy of manufacturing only one chassis was put into effect, that the success of the company started on a scale which until then was entirely unknown in the automobile world. An official of the company stated that if the old policy of building several types of cars, fours and sixes, with chassis of various sizes, had been maintained that the Ford company would not have been able to become the big concern it is to-day.

The general outlook of business is satisfactory to the Ford officials. Conditions throughout the country are reported to be greatly improved over what they were several months ago.

In three years the total assets of the company have almost tripled, totaling $20,815,783.63 in 1912, $35,033,919.86 in 1913 and amounting to $61,632,257.16 in September, 1914.

The total of the surplus for the last three years was near the hundred million mark last September, the exact figures being $91,696,301.32.

FORD BALANCE SHEET

Assets	1914	1913	1912
Cash on hand and in banks...	$27,441,468.79	$13,225,710.82	$ 6,400,100.66

Reo Ends 1914 Season—Big Gains

LANSING, MICH., Nov. 14—Four days ago the Reo Motor Car Co. shipped the last of its 1914 models.

"This has been a big and good year," said sales manager R. C. Rueschaw, "and from all indications next year will be even better. All departments except the paint and trimming departments are working with their full force, which means that 1,800 men are at work. Just as soon as the necessary raw material is on hand the two other departments will be also working and then we will have a force of 2,200 men and women on the pay roll.

"Conditions have greatly changed in the automobile business. In years not so far distant the trade gradually dropped off from August to January, when the new season started. This year August, as far as we are concerned, was a bigger month than July, while September and October were very good indeed."

National conference of salesmen of Goodyear Tire and Rubber Co., held recently at the factory in Akron, O. There are 1,000 men in the picture;

To Make Armored Truck with Gun Turret

Will Mount Bodies Made by an Armor Plate Firm on Federal Truck Chassis

NEW YORK CITY, Nov. 17—For the purpose of turning out an armored truck mounting two machine guns in a revolving turret, the Armored Motor Car Corp. has been formed by J. H. Allen, 2 Rector street, this city, eastern representative of the Elyria Iron & Steel Co. It is incorporated for $6,000. Mr. Allen has a patent covering the application of the revolving turret to a motor truck.

The steel bodies will be built on contract and will be mounted on a 2-ton Federal chassis; the body will weigh 3,000 pounds, leaving a margin of 2,700 pounds for the two guns, operators and ammunition. The first car will be completed in about 3 weeks and will be displayed in the salesrooms of the Federal Truck Co., 146 West Fifty-second street.

Twelve chassis comprise the first order. The bodies will be made by an armor-plate company and shipped to the Federal plant in Detroit where they will be mounted on the chassis. The vehicles will be manufactured for the United States government as well as for governments of foreign countries.

Counselman Retires from Active Service

DETROIT, MICH., Nov. 14—Lee Counselman, who has been vice-president and general manager of the Chalmers Motor Co. during the last few years, has retired from active service. Lee R. Olwell, who was assistant general manager, is now general manager, and Treasurer Clarence A. Pfeffer has been made assistant general manager and continues as treasurer. Mr. Counselman continues his connection with the Chalmers company as one of the vice-presidents and a member of the board of directors.

S. A. E. Standards Committee in Session

NEW YORK CITY, Nov. 18—With more than thirty-five in attendance the convention of the standards committee held in the rooms of the Society of Automobile Engineers opened yesterday. The work scheduled for the 3 days' session includes the reports of fourteen divisions as listed in THE AUTOMOBILE for November 5, page 864.

The schedule for yesterday called for the reports from the divisions on commercial car wheels, truck standards, motor testing, electrical equipment and miscellaneous fittings. Reports were submitted and the work outlined for the remaining period before the annual meeting of the society which takes place January 6 and 7 at the Engineering Societies Building in this city.

The custom of advancing mileage to the members of the standards committee from out of town was inaugurated at this meeting and the result was an augmented attendance. Those attending on the first day of the conference were the following:

Joseph Bijur, Bijur Motor Lighting Co.; Leonard Kebler, Ward Leonard Electric Co.; R. J. Nightingale, Willard Storage Battery Co.; Henry Souther, Ferro Machine and Foundry Co.; Alexander Churchward, Gray & Davis Co.; Russell Hoopes, Hoopes Bros. & Darlington; H. G. Osburn, National Metal Molding Co.; R. L. Morgan, Consulting Engr.; H. H. Buswell; Henry B. Coleman, F. S. Lee; Chester E. Clemens, Perfection Spring Co.; C. B. Williams, Mott Wheel Company; Alden McMurtry, Consulting Engr.; J. G. Perrin; R. S. Bryant, Standard Welding Co.; C. J. Welch, U. S. Tire Co.; A. H. Ehle, Baldwin Locomotive Works; W. P. Kennedy, Consulting Engr.; R. McA. Lloyd; C. T. Meyers, Mechanical Engr.; T. V. Buckwalter, Pa. R. R.; E. R. Whitney, Commercial Truck Co.; W. H. Conant, Gould Storage Battery Co.; W. S. Gould; H. W. Harper, Howard Miniature Lamp Co.; C. M. Bunnell, Edison Lamp Works; H. D. Church, Packard Motor Car Co.; V. G. Apple, Splitdorf Electrical Co.; A. D. Libby, Splitdorf Electrical Co.; B. B. Bachman, Autocar Company; and J. J. Aull, Lunkenheimer Co.

Metropolitan S. A. E. To Discuss Eights

NEW YORK CITY, Nov. 18—At the monthly meeting of the Metropolitan Section of the Society of Automobile Engineers, to be held at the Automobile Club of America, November 24 at 8 p. m., the subject of eight-cylinder motors will be discussed.

A paper on this will be presented by D. McCall White, the designer of the Cadillac eight and a number of engineers prominent in the trade have been invited to take part in the discussion following the presentation of the paper. Preceding the meeting there will be an informal dinner at the Automobile Club of America.

Miller Rubber Earns 10 Per Cent. on Common

AKRON, O., Nov. 13—Stockholders of the Miller Rubber Co. today re-elected the retiring officers. General Manager W. F. Pfeiffer's report showed sales for the past year exceeding $2,500,000. The net profits amounted to $528,000, sufficient to pay 7 per cent. on the preferred and 10 per cent. on the common stock, and allowing for depreciation on buildings, machinery and tools and crude and finished products.

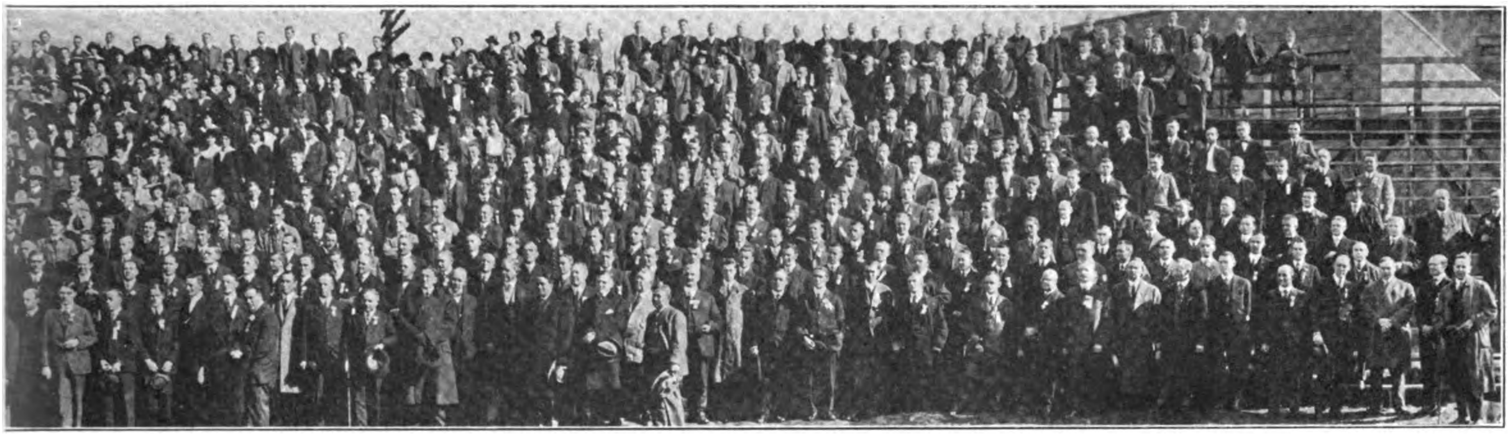
The officers are as follows: President, Jacob Pfeiffer; vice-president, C. T. Grant; treasurer, F. B. Theiss; secretary and assistant treasurer, W. F. Pfeiffer. They, with J. M. Doran, comprise the board of directors.

Fighting Financial Problems

DAYTON, O., Nov. 17—Upon the application of J. I. Baker, president and general manager, T. W. Baker was appointed receiver for the Dayton Electric Car Co., of this city. The company has been manufacturing electric automobiles for some time.

President Baker claimed that he was surety on notes aggregating $20,000, of which $19,000 was past due, and since other creditors were demanding payment it was thought best to petition for a receiver. He declared that the assets would not be sufficient to meet all of the claims against the company if an attempt were made to do business as formerly. The company has a large number of electric automobiles, buggies and carriages on hand. A request has been made to sell the property and distribute the proceeds.

MILWAUKEE, WIS., Nov. 9—The Universal Machinery Co., 1916 St. Paul avenue, Milwaukee, formerly a producer of



550 salesmen, branch managers, etc., including part of the Canadian organization; the remainder are members of the reception committee

Universal motor trucks and more recently a builder of small gasoline engines for motorcycle, cyclecar and light car purposes, has filed a voluntary petition in bankruptcy. The assets are given as $68,352 and liabilities as $59,957 at the present time.

Crescent Motor Liabilities $485,590.32

CINCINNATI, O., Nov. 14—Listing liabilities at $485,590.32 and assets at $428,968.45, the Crescent Motor Co., bankrupt of this city, yesterday, through its president, W. T. Hunter, filed its schedules in bankruptcy in the United States District Court.

The plant of the company is located at Carthage, where it occupies a 10-acre tract. This is listed as having a value of $170,445. It is the main item in the assets. The stock on hand is appraised at $159,159 and the machinery at $68,044. Other personal property belonging to the company is listed as worth $22,425, and the debts due to the company aggregate $5,865.

The secured debts amount to $211,126 and the unsecured to $189,604, while there is liability also on bills and notes of others to the amount of $82,794.

DETROIT, MICH., Nov. 17—The Detroit Electrical Appliance Co., manufacturer of Deaco starters, was adjudged bankrupt on November 16 in the Federal Court, this city. Schedules have not been filed.

PORT HURON, MICH., Nov. 16—The Havers Motor Car Co., this city, was today adjudged bankrupt in the Federal Court, Detroit, Mich. Schedules have not been filed.

DETROIT, MICH., Nov. 17—An added 4 per cent. dividend, making a total of 45 per cent., is to be paid creditors of the Grabowsky Power Wagon Co. This will total about $880,000. Also, another 3 or 4 per cent. dividend is in prospect.

Overland Adds 17 Acres of Floorspace

TOLEDO, O., Nov. 18—*Special Telegram*—Although additions to the plants of the Willys-Overland Co., embodying 25 acres of floorspace have just been completed. It is announced today that two additional buildings will immediately be erected. The first of these, which is believed will be one of the largest factory buildings ever constructed, will be 1,000 feet long and 200 feet wide and have two stories and basement. The other will be 200 feet square. The additional floorspace will approximte 17 acres, swelling the total at the Toledo plants to 79 acres. With these additions Overland will have the largest aggregate space of any motor car plant in the world, it is claimed.

The largest of the new structures will be devoted to painting and upholstering departments and repairs and body assemblies. The other addition will join on to the just completed body assembly and machine work plant which now measures 200 by 400 feet, and therefore the latter is scheduled for an enlargement of 500 per cent. Reasons given for these tremendous additions are only that the growing demand has required the expansion. October was the biggest month the concern ever experienced, the sales representing more than $5,000,000. It is interesting to note that the largest of the above additions will have an area more than twice as great as that of the entire original Toledo factory when it was purchased by John N. Willys a little over 5 years ago.

Curb Market Opens with Renewed Activity

NEW YORK CITY, Nov. 16—Renewed activity, with considerable strength here and there, characterized the official resumption of trading in the curb market today. The curb market, however, was unofficially opened on November 12. Most of the securities were fairly steady. Kelly-Springfield tire retained its firmness, selling at 52 and 53, as compared with the previous day's high of 53. A market was established for Willys-Overland common stock at 68 and 70, but no sales in this issue were reported. Transactions in Maxwell Motors common stock took place at 14 and 14¼, off, in the last case, ¼ point from the close. Trading in Standard Oil issues today was in moderate volume, with price changes erratic. Vacuum oil was steady at 180 and 185.

Market Reports for the Week

Few changes occurred in this week's market reports. Those that did occur were mostly in the metal markets and were unimportant, with the exception of lead which went up $0.20 per 100 pounds, closing at $3.70. This product was very strong at the closing. The American Smelting & Refining Co. advanced the prices 10 points for shipment from the West in 50-ton lots. There were few customers to be found on Tuesday for copper. Electrolytic has been selling at higher prices with considerable buying at the early part of the week. But on Tuesday, few buyers could be found and the tone was less strong and prices more or less nominal after the feverish excitement and large sales. Tin was dull and lower with scarcely any demand even for nearby positions. There were no changes in the oils and lubricants markets.

Marmon 41 Makes 62.89 Miles in 1 Hour

Stock Touring Car with Five Passengers and Top Up Electrically Timed

INDIANAPOLIS, IND., Nov. 12—A Marmon Model 41 registered stock touring car traveled 62.89 miles in 1 hour on the Speedway today, carrying five passengers, and having top and windshield up. The test was under sanction of the American Automobile Association, and was directly supervised by F. E. Edwards, technical representative of the Contest Board, and C. S. Ricker, Speedway representative. The timing was recorded electrically.

This speed will constitute new stock car records in America for a car with five people and weighing with load 5,310 pounds and without load 4,570 pounds. The wind-resisting area of the car measured 40.8 square feet. The motor is a six-cylinder one, 4 1-4 by 5 1-2 and during the test it was operating at a crankshaft speed of 2,032.9 revolutions per minute. The gear ratio in the rear axle was 3.46 to 1 and 36-inch tires were used.

In addition to the test constituting a new record for 60 miles, the records are also claimed for intermediate distances and application made to the Contest Board of the A. A. A. for formal declarations of these records. The intermediate records are:

Distance	Time	M.P.H.
10 miles	9:34.99	62.7
20 miles	19:09.98	62.6
30 miles	28:43.02	62.7
40 miles	38:13.80	63.4
50 miles	47:44.77	62.85
60 miles	57:14.71	62.9

After the test was completed the engine was dismantled for the purpose of determining to what extent the parts had worn, the report simply stating that no appreciable wear of parts was disclosed.

Speedway Wants 1,000-Mile Fuel Test

INDIANAPOLIS, IND., Nov. 14—The Indianapolis Motor Speedway has applied for an A. A. A. sanction for November 18 and 19 to conduct a 1,000-mile test on a gasoline substitute known as synthetic fuel and which was recently tested in this city. The test is to be 500 miles each day and will be conducted by A. A. A. officials. The new fuel, it is claimed, can be manufactured at 2 cents a gallon, and is the invention of John Andrews, McKeesport, Pa. At the recent test in July a six-cylinder National, weighing 3,800 pounds, made 12.5 miles on a gallon of this fuel, in contrast with 15.2 miles per gallon of 64 gravity gasoline. In similar tests a Marmon six made 12.2 miles per gallon on the synthetic fuel, and was later run 100 miles on the road after which the valves did not show any special carbonization.

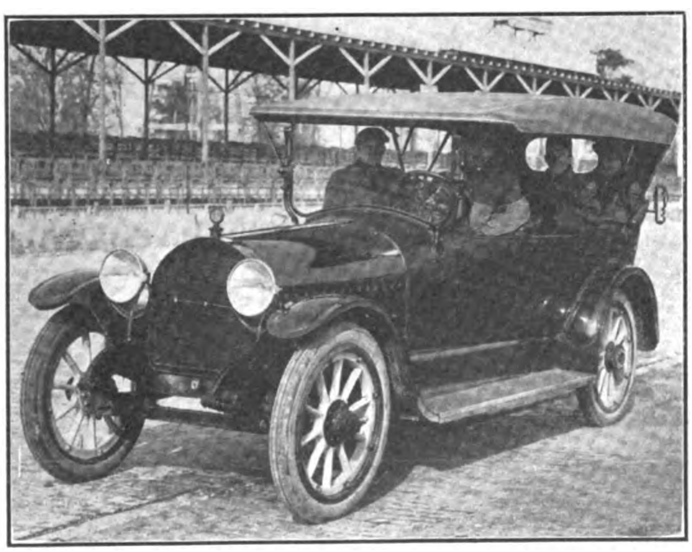
Earl Cooper Stars at Phoenix Track

PHOENIX, ARIZ., Nov. 16—Earl Cooper, winner of the Corona road race, was the star of the race meet held at the Arizona fair grounds track Thursday, November 12. Cooper and his Stutz won the principal event of the day, the 50-mile, in 47:59. The previous 50-mile record for an Arizona track was 50:53, set by Teddy Tetzlaff in his Fiat Cyclone a year before.

Barney Oldfield and the Cyclone were leading in the 27th mile, when a broken water connection put Oldfield out of the race. From that time on it was a struggle between Cooper and Art Klein, in the King. Each made one stop for tires. The little Maxwell, driven by W. W. Carlson, went to the finish without a stop but finished on one flat tire. These were the only cars to finish. Oldfield's Stutz, driven by George Hill, went out in the first 5 miles. Klein's time was 48:13 and Carlson's, 53:05.

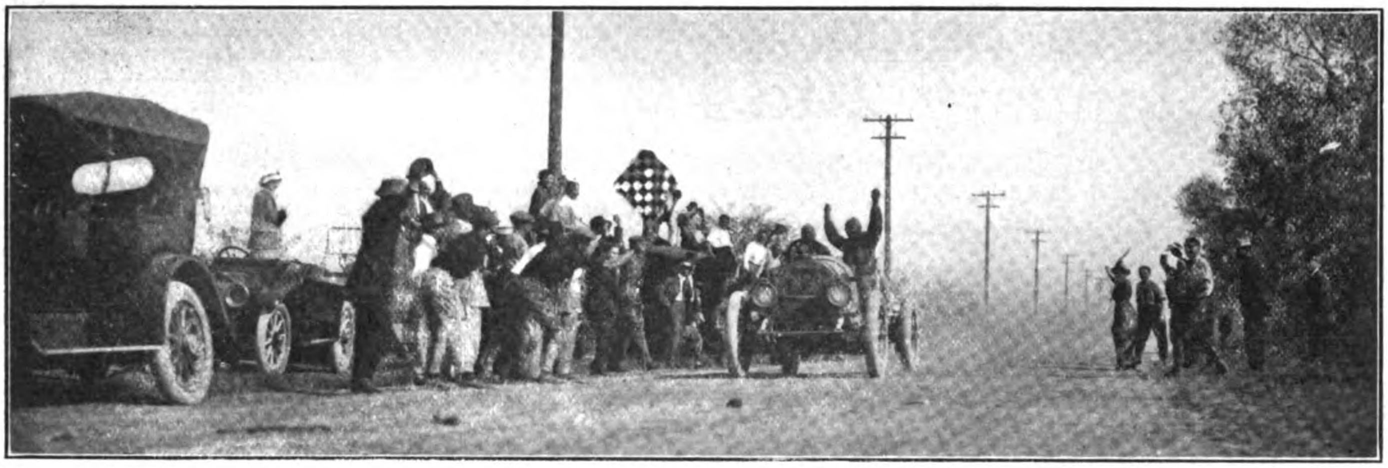
There were two events exclusively for the cars that participated in the road races from Los Angeles and El Paso, and Oldfield won both easily. His time for the 15-mile event open to all cars that participated in the desert races, was 14:54. Jack Smith, Buick, was second in 15:05; Hugh Miller, Pope, third, 15:21 2-5; Lew Gasser, Stutz, fourth in 15:22 3-5. All except Oldfield were in the race from El Paso.

The race for cars finishing first and second in the desert races was limited to 5 miles. Oldfield was first in 4:59; Hugh



Marmon 41 stock touring car which made 62.89 miles in 1 hour in official tests held at Indianapolis Speedway. Note five passengers and top and windshield raised

Electrical timing device used in Marmon 41 trial. Left to right, officials are: F. E. Edwards, A. A. A.; C. S. Ricker, Speedway; Theodore Myers, Timer; H. E. Glover, assistant



Winning the El Paso-Phoenix race. Miller's Pope-Hartford with Ed. Orr driving crossing the line

Miller, Pope, second; John Hutchins, Buick, third; Louis Nikrent, Paige, fourth. The summary:

50-MILE

Car	Driver	Time	Car	Driver	Time
Stutz	Cooper	47:59	Maxwell	Carlson	53:05
King	Klein	48:13			

15-MILE

Car	Driver	Time	Car	Driver	Time
Stutz	Oldfield	14:54	Pope-Hartford	Miller	15:21 4/5
Buick	Smith	15:05	Stutz	Gasser	15:22 4/5

5-MILE FOR CARS FINISHING 1 AND 2 IN DESERT RACE

Car	Driver	Time	Car	Driver	Time
Stutz	Oldfield	4:59	Buick	Hutchins	—
Pope-Hartford	Miller	—	Paige	Nikrent	—

Pope-Hartford Won El Paso-Phoenix at 50 M.P.H.

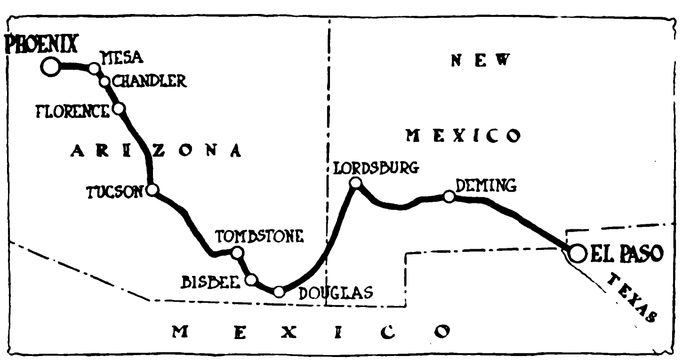
PHOENIX, ARIZ., Nov. 13—It was at over 50 miles an hour and with one rear wheel wobbling about on cracked and splintered spokes that Ed. Orr in Hugh Miller's Pope-Hartford finished winner of the El Paso-Phoenix race, as reported in THE AUTOMOBILE for November 12. He had no engine trouble and changed only two tires in the 533 miles but his car turned turtle on a sharp curve 12 miles west of Bisbee, the night control, throwing Orr and Miller out and cracking the spokes in a rear wheel. The car was righted with poles and won the race.

J. T. Hutchins, who finished second in a Buick, had little trouble but changed tires several times. Tom Brewer, who drove a Marmon to third place, changed twelve tires and those on which he finished were worn through the fabric. Fourth place went to L. E. Cornu, whose Palmer-Singer went out at Lanark, N. M., with engine trouble, and who finished in a Stutz. Of the twenty-seven starters, only ten reached Phoenix. Nine went out the first day.

Winners Divide $5,600 Purse

The four winning cars divided a purse of $5,600, the Pope-Hartford, first, taking $2,800; the Buick, second, $1,400; Marmon, third, $840; and Stutz, fourth, $560. In addition, the cities of Bisbee and Tucson gave $1,000 and $500, respectively for the cars making the best time to these points. The Pope-Hartford and the Buick took first and second places straight through. Brewer's Marmon was third at Phoenix and Bisbee. Cornu's Stutz was fourth at Phoenix, third at Bisbee and fourth at Tucson. Leonard's Buick was fourth at Bisbee.

The times of the winning cars were: Pope-Hartford, 14:35:48; Buick, 15:57:01; Marmon, 16:37:28; and Stutz, 16:41:34. The average time of the winner was 37.3 miles per hour.



Map of course followed in El Paso-Phoenix race

RUNNING TIMES IN EL PASO-PHOENIX RACE

Car	Owner	Driver	Town	Running Time to Bisbee Night-Control	Running Time El Paso to Phoenix
Pope-Hartford	H. B. Miller	H. B. Miller	Phoenix	7:31:03	14:35:48
Buick	J. T. Hutchings	J. T. Hutchings	Alamogordo	8:09:14	15:57:01
Marmon	Tom Brewer	Mrs. W. G. Shanley	Globe, Ariz.	8:48:00	16:37:28

Krit	S. W. Auto Sales Co.	R. Peak	El Paso	....	Scratched.
Buick	G. M. Dubois	L. J. Freeman	Phoenix	....	Out at start.

Importers' Salon January 2 to 9

More Exhibitors Expected Than Ever Before—More Accessories at N. Y. Show

NEW YORK CITY, Nov. 14—The Automobile Salon, as the exhibition of foreign built motor cars held annually in New York, is known, will be held January 2 to 9 in the Grand Ball Room of the Astor as heretofore.

The 1915 Salon will be conducted as usual by the Automobile Importers' Alliance, of which E. Lascaris is president, T. E. Adams, vice-president, and Stefan J. Kjeldsen, secretary. Mr. Kjeldsen, who managed this annual event for many years past, will again serve in the same capacity.

From present indications the 1915 Auto Salon promises to have a larger list of exhibitors and to be more of a success generally, than any of its predecessors. Many of the foreign automobile factories are continuing in operation, on government work, and they have been able to complete the special chassis and finished cars, which they began to build before the war started. These special jobs are comparatively few in number, and not adapted to army use, so that there will be no difficulty in getting them over in time for the show.

Providence Shows 44 Cars and 15 Trucks

PROVIDENCE, R. I., Nov. 14—Rhode Island's annual automobile show opened this evening at the State Armory, at Providence, and it was thronged by an eager crowd. There was much interest centered in such cars as the new eight-cylinder Cadillac, the Dodge car, the Briscoe, the small Peerless, the four-cylinder Stearns-Knight, the new Overland Six and the new five-passenger Hupmobile, all of which made their debut for show purposes in the East. The show will continue all next week. On Wednesday there will be a double attraction when the price is increased, for it will be combined Society day and Governor's night. Many of the Boston dealers are here to spend the week, and a large number of dealers who are located in Southern Massachusetts will be prominent at the various spaces.

The show is not wholly a passenger car exhibition, for in the basement there are fifteen different makes of trucks. Scattered about are thirteen different accessory dealers, making a total display of some seventy-two exhibits in the building.

Multibestos Men Hold Convention

FRAMINGHAM, MASS., Nov. 13—At the recent sales convention of the Standard Woven Fabric Co., of this city, manufacturers of brake lining, technical questions which came up in connection with brake-lining sales were covered by E. E. Waite, factory manager of the company, in his talk on "Multibestos Compared with Other Brake Linings." Mr. Waite took the representatives through the factory and explained each manufacturing process. He then gave the engineering data on a number of brake lining tests which he himself had made, and also of tests which had been made by several automobile manufacturers.

General Manager Burdick gave a talk in which he traced the history of this company's success. According to his report business has been doubled in the past year.

Although the convention was decidedly of a business nature there was also a social side. One evening was spent at the Framingham Country Club with Mr. Burdick as host.

Another convention is planned for January, when representatives from the Chicago and San Francisco offices will be present.

Dealers Organize Association in Boston

BOSTON, MASS., Nov. 14—The Massachusetts Automobile and Accessory Dealers' Assn. was formed in Boston today as a result of several meetings at which more than 100 dealers have aired their views on the trade in motor accessories. The new organization starts off with about seventy-five members and it is expected that this number will be doubled within a short time when the dealers in other cities can be brought in. George P. Brophy has been chosen president and Joseph Everett, secertary. At the next meeting a board of directors will be elected, and also other officers.

G. M. C. Directors and Officers Re-elected

DETROIT, MICH., Nov. 18—At the annual meeting of the General Motors Co., the retiring directors were re-elected. The directors re-elected the officers. The board of directors consists of Thomas Neal, chairman, Joseph Boyer, E. W. Clark, W. C. Durant, R. F. Herrick, J. H. McClement, E. D. Metcalf, C. S. Mott, M. J. Murphy, C. W. Nash, J. J. Storrow, Albert Strauss, N. L. Tilney and Jacob Wertheim. The officers are as follows: President, C. W. Nash; vice-presidents: E. W. Clark, W. C. Durant; secretary, Standish Backus; J. T. Shaw, treasurer; and comptroller, W. H. Alford.

Packard Paris Manager Sees Business Opportunity

DETROIT, MICH., Nov. 17—*Special Telegram*—Manager R. N. Goode, of the Paris branch of the Packard Motor Car Co., is here for a short business stay. He says business conditions are improving in France and England, and Paris business men who had left the city when the Germans were so near it, are now returning and reopening their stores. American manufacturers could do big business now in countries at war and they should receive assistance from the American government which should show them how to get that business. There is a very big waste of automobiles among the French because so many cars are driven by incompetent men.

Maxwell Representatives Meet in Detroit

DETROIT, MICH., Nov. 17—A convention at which sixty district representatives and salesmen of the Maxwell Motor Co., was held at the main offices of the Maxwell company yesterday and today. The men came from the Middle Western, Eastern and Southern states for the purpose of becoming more familiarized with the general Maxwell business methods and policy and get first hand knowledge about the construction of the Maxwell cars. Yesterday the visitors were given talks by Walter M. Anthony, comptroller of the Maxwell company, who spoke on financial matters; C. E. Stebbins, sales manager, who spoke on salesmanship; J. A. Vail, chairman of the board of directors, on business conditions, C. R. Newby, zone supervisor, on starting and lighting systems. Informally many other subjects were discussed. Today the zone or district supervisors conducted the men from their respective zones or districts through the factory acting as their guide and instructor.

NEW YORK CITY, Nov. 14—Applications for show space still continue to pour in on the National Automobile Chamber of Commerce for both New York and Chicago shows. Following is a list of those companies who secured space during the past week:

Additional Accessory Exhibitors for New York and Chicago Shows

AT BOTH SHOWS

Atlas Automatic Jack Corp........New York City
Brown Trafilog Co................Cleveland, Ohio
Curtis Pneumatic Mach. Co........St. Louis, Mo.
Hydraulic Pressed Steel Co.......Cleveland, Ohio
Massnick-Phipps Mfg. Co...........Detroit, Mich.
A. J. Picard & Co................New York City

NEW YORK

American Die & Tool Co.............Reading, Pa.
Ashley Steel Bldg. Co.............New York City
Atlas Automatic Jack Corp........New York City
Auto Air Appliance Co............Baltimore, Md.
Eugene Bournonville Welding Co..Cleveland, Ohio
Brown Trafilog Co..............Cleveland, Ohio
Curtis Pneumatic Mach. Co........St. Louis, Mo.
General Rim Co.................Cleveland, Ohio
Gerhart Motorcycle Co...........Harrisburg, Pa.
Hydraulic Pressed Steel Co......Cleveland, Ohio
Hydraulic Oil Storage Co.........New York City
Lane Bros. Co..............Poughkeepsie, N. Y.
Massnick-Phipps Mfg. Co..........Detroit, Mich.
Metal Specialties Co................Chicago, Ill.
Micro Piston Ring Co............New York City
A. J. Picard & Co...............New York City
W. S. Sheppard..................Newark, N. J.
Universal Car Equipment Co........Detroit, Mich.

CHICAGO

Atlas Automatic Jack Corp........New York City
Brown Trafilog Co..............Cleveland, Ohio
Currier-Koeth Mfg. Co..........Coudersport, Pa.
Curtis Pneumatic Mach. Co........St. Louis, Mo.
Gould Storage Battery Co.........New York City
Hydraulic Pressed Steel Co......Cleveland, Ohio
Massnick-Phipps Mfg. Co...........Detroit, Mich.
A. J. Picard & Co...............New York City
Positive Supply Co..............Davenport, Iowa

Factory Miscellany

FORD Plant for Buffalo — The Ford Motor Co., Detroit, Mich., has bought four large parcels of property in Buffalo, N. Y., extending northeasterly from Main street and the New York Central Belt Line, along Main street to Rodney street, to Halbert street, to within 150 feet of Jewett avenue. The property has a street frontage of over 900 feet and nearly 470 feet of frontage on the Belt Line. It is the intention of the company to build in the spring a four-story building on practically the entire site. The structure will be of reinforced concrete. It is estimated that the land, building and development of the site will represent an investment of fully $500,000.

Ward Co. Erecting—The Ward Motor Vehicle Co., Mt. Vernon, N. Y., will erect a factory 162 by 301 feet.

Blair Truck Adds—The Blair Motor Truck Co., Newark, O., will erect a factory building on Sixteenth street, Newark.

Davis Co.'s Plant—The A. R. Davis Motor Co., 2034 Euclid avenue, Cleveland, O., will erect a two-story plant, 50 by 170 feet.

Hess-Bright's Addition—The Hess-Bright Mfg. Co., Philadelphia, Pa., has just broken ground for a three-story addition to its plant, 38 by 200 feet.

Vulcanizing Products Co. Builds—The Haslop Vulcanizing Products Co., Johnstown, Pa., has purchased a site in Coopersdale, a suburb, and plans to erect a new plant.

Milwaukee Company Piston Maker—The Central Foundry Co., 705-723 Park street, Milwaukee, Wis., has established a department for the production of pistons, piston rings and cylinder castings.

Philadelphia Company Adds—The Auto Sales & Service Co., Philadelphia, Pa., will erect a two-story addition to its plant at Third and Chestnut streets.

Maher to Manufacture Accessories—The Maher Mfg. Co., Libertyville, Ill., will establish a plant for the manufacture of lighting fixtures and automobile accessories. N. L. Maher is interested.

Manhasset Co. Building—The Manhasset Mfg. Co., manufacturer of tire fabrics, Putnam, Conn., has begun the construction of a two-story addition to its plant having 10,000 square feet of floor space.

Will Manufacture Carbureters—Williams & Co., 58 Parks street, Niagara Falls, Ont., will install machinery for the manufacture of carbureters and complete equipment for general garage and automobile repairs.

Service Station in Burlington—The Lane Mfg. Co., Montpelier, Vt., the general distributor for the Cole car and the Kissel truck, will on December 1 open a branch salesroom and service station at Burlington, Vt. C. A. Ni[illegible] will be in charge as sales manager.

Federal Employees' Club—A "Federal Rubber Goodfellowship Club" has been organized by the employees of the Federal Rubber Mfg. Co., Milwaukee, Wis., the purpose being to accumulate a fund which, about Christmas, will be used to bring good cheer into the homes of the needy.

Burnox Co. Carbon Remover Manufacture—The Burnox Co., West Allis, Wis., has been organized by Theodore Mueller, Paul Hunt and Charles E. Kubicek to manufacture and market a chemical compound for removing carbon deposits in internal combustion engine cylinders. Headquarters are in West Allis, Milwaukee county.

Overland Buys More Land—For the purpose of squaring a tract of land owned by the Willys-Overland Co., Toledo, O., back of Central Grove Park, that company has purchased a small strip, approximating about 1 acre. No immediate use is to be made of the purchase, but, like the tract to which it is to be attached, it is to be held for future development.

To Manufacture Valve Grinder—Forrest E. Devine, of Madison, Wis., inventor and patentee of a gang grinder for reseating valves in poppet-valve engines, by means of which all of the valves of a multiple-cylinder engine may be ground at one time, is preparing for a large production of the appliance, having secured the co-operation of one of the largest motor supply houses in Chicago in the direction of marketing the goods.

Auto Body Plant Nearly Completed—The Auto Body Co., Lansing, Mich., has nearly completed a new addition to its plant, the addition being for the purpose of housing the woodworking machinery and making it more convenient to caring for the rough timber stuff that is used in the manufacture of its bodies. The addition will give the company a plant a block long and with an L half a block long. The company has shown a remarkable growth in the decade elapsing since its organization on a capital of a few thousand dollars for the manufacture of automobile and buggy bodies.

May 29............Indianapolis, Ind., 500-Mile Race, Indianapolis Motor Speedway.
Sept. 20-25.......San Francisco, Cal., International Engineering Congress.

The Week in  the Industry

Motor Men in New Roles

REID Anderson Sales Manager—The Anderson Electric Car Co., Detroit, Mich., has appointed T. C. Reid to the position of manager of sales for Detroit and Wayne county. Mr. Reid has been with the Anderson company for the last 6 months, and during the previous 18 months was connected with other electric vehicle interests in this city.

Oley Now Manager—W. S. Oley has been appointed manager of the Maxwell-Metz Motor Co., Portland, Me., to succeed B. H. Gettis, who has returned to Detroit.

Sessions Sales Manager—The Porto Metal Garage & House Co., Thirty-seventh and Burnham streets, Milwaukee, Wis., has appointed R. N. Sessions as sales manager.

Rose in England—C. B. Rose, chief engineer of the Velie Motor Vehicle Co., Moline, Ill., is now at the Hotel Cecil, London, England, investigating the truck industry in army circles.

Pelletier Writing Reo Advertisements—E. LeRoy Pelletier will write the advertisements for the Reo Motor Car Co., Lansing, Mich. He will write no other gasoline automobile copy.

Benjamin Residing in Detroit—C. Arthur Benjamin, sales manager of the George W. Houck Co., Buffalo, N. Y., has become a resident of Detroit, Mich., where he will take care of the sales.

Jardine Returns from England—Robert Jardine, who has been in England and on the Continent for the past 6 months in the interests of the Rich Tool Co., London, S. W., has returned to the States.

Potter Leaves Oxford—M. H. Potter has resigned as chief engineer and factory manager of the Oxford Motor Cars & Foundries, Ltd., Montreal, Que. His plans for the future are undetermined, but he will no doubt remain in Canada.

Cartwright Heads Body Co.—The Commercial Automobile Body Co. has opened offices and sales rooms in St. Louis, Mo. Hugh Cartwright is president and general manager. He was for 17 years vice-president of the Banner Buggy Co. there.

Little Gets New Appointment—W. C. Little has been appointed representative for Michigan and Ohio by Brandenburg & Co., manufacturers' representatives of New York, Chicago and Detroit. Mr. Little's local headquarters are at 1311 Dime Savings Bank Building, Detroit, Mich.

Wittstein Knox Efficiency Engineer—H. L. Wittstein, who for the past year has held the position of supervisor of records for the Knox Motors Co., Springfield, Mass., has been appointed efficiency engineer of that company. Mr. Wittstein is a graduate of Sheffield Scientific School.

Bradfield Resigns—H. C. Bradfield, who has been connected with the Cole Motor Car Co., Indianapolis, Ind., for 4 years, in publicity work, has resigned. During the past 2 years he has been special traveling representative of the company in the West. A. S. Blakely succeeds Mr. Bradfield.

Garage and Dealers' Field

Howard Makes a Move—The F. S. Howard Motor Car Co. agent in Worcester, Mass., for the Mitchell and Chevrolet lines, has moved into new quarters at 746 Main street.

Milwaukee Company a Klaxon Dealer—The Western Motor Supply Co., 408-410 Jefferson street, Milwaukee, Wis., has been appointed Wisconsin distributor of Klaxon horns.

Ford's $100,000 Cotton Purchase—The Ford Motor Co., Detroit, Mich., has joined the bankers' pool recently organized in the South to help the cotton growers and has subscribed $100,000. This represents the purchase price of more than 3,300 bales of cotton.

Philadelphia Stevens-Duryea Moves—The F. Winsor Eveland Co., distributors of the Stevens-Duryea car, formerly located at Nos. 202-204 North Broad street, Philadelphia, Pa., has removed to Ridge avenue above Broad street. The company has taken over the business from the former agents, A. G. Spalding & Bros.

Twombly Taxi Service in Philadelphia—The Stoever-Hannold Co., Motor Mart, No. 605 North Broad street, Philadelphia, Pa., local representatives of the Twombly car, announce the early inauguration of a new Philadelphia taxi service, which is to use the company's underslung taxi. The maximum charge for use of the new taxi is to be 25 cents a mile, a considerable reduction in present rates.

New Marathon Tire Distributors—The appointment of additional territorial distributors has been made by the Marathon Tire & Rubber Co., Cuyahoga Falls, O. Within the past 2 or 3 weeks the following appointments have been made: Turner Electric Supply Co., Birmingham, Ala.; E. L. Taylor Co., Inc., Richmond, Va.; Frank Bros., Baltimore, Md.; Peerless Rubber Tire Co., Seattle, Wash., and the Denmead Auto Supply Co., Akron, O.

New Wilmington Bus Line—The Postles Auto Brokerage Co., of Wilmington, Del., has decided to inaugurate a daily automobile service from Wilmington to points in Kent and Sussex counties, chiefly for the handling of passengers, with a view to including freight if the demand is sufficient. A sixteen-passenger steamer will be first used, but later there may be five five-passenger cars instead, which would divide the territory.

Peerless Agency in Providence—Following the change in Boston whereby the business of the Peerless Motor Car Co., Providence, R. I., was turned from a factory branch to an agency, the business in Rhode Island has also been transformed. At Providence there was a sub-branch identified with the Boston one, and now this has become an agency. J. W. Breese, who was manager, having bought out the business on his own account. He has moved the ouarters from 37 Chestnut street to 27 Snow street, where he shares salesrooms with the J. C. Tucker Co., with service station in the rear.

Recent Incorporations in the Automobile Field

New York

NEW YORK—P. J. Durham Co.; capital, $10,000; motor cars. Incorporators: Percy J. Durham, 255 W. 55th street; Henry A. Maslin, 1122 Finlay avenue; Frederick C. Wulf, 707 Gates avenue, Brooklyn.

NEW YORK—Elite Taxicab Co.; capital, $10,000; Incorporators: Anna M. Dwyer and John F. Dwyer, both of 1080 Bryant avenue; Frank J. Dwyer, 418 West 14th street.

NEW YORK—Famous Packard Auto Renting Sorporation; capital, $5,000. Incorporators: Charles J. Clavin, 317 West 44th street; Theresa V. Moore and Joseph Clavin, both of 668 8th avenue.

NEW YORK—Goodyear Tire & Rubber Co.; capital, $1,000; to represent the Ohio corporation in Eastern United States and deal in its products. Incorporators: James W. Hobbs, 1972 Broadway; George Morris and Francis K. Raynor, both of 115 Broadway.

NEW YORK—Holt-Welles Co.; capital, $50,000; motor car supplies, etc. Incorporators: Calvert Holt and Edward H. Stickels, both of 1790 Broadway; Paul Welles, 463 West street.

NEW YORK—Monmouth Garage; capital, $10,000. Incorporators: Henry R. Wohlers, Franklin J. Griesbeck and John S. Johnston, all of 140 Broadway.

NEW YORK—Overland Service Station; capital, $1,000; general motor vehicle business. Incorporators: John Q. Bachman, 293 Webster avenue; George V. Harriman, 355 West 56th street; Edward F. Stoeckle, 354 West 56th street.

NEW YORK—Reliable Tire & Supply Co.; capital, $5,000. Incorporators: Bluma Sekoson and Estelle Sekosen, both of 934 East 179th street. Louis H. Lax, 429 West 30th street.

NEW YORK—Shears Selling Organization; capital, $20,000; motor cars. Incorporators: James E. Taylor, Theodore C. LeFevre and M. H. Briggs, all of 30 Church street.

NEW YORK—Spar East Co.; capital, $60,000; motor car supplies, etc. Incorporators: Alec H. Seymour, Roy E. Hallock and William H. Natter, all of 27 Pine street.

Ohio

AKRON—Akron Tire & Tube Co.; capital, $10,000; to manufacture tires, tubes, etc. Incorporators: L. L. Hunsicker, L. E. Hunsicker, W. C. Diemer, C. E. Smith and J. Diemer.

CELINA—National Mutual Automobile Insurance Association. Incorporators: L. M. Murlin and others.

CLEVELAND—Cleveland Electric Motor & Mfg. Co.; capital, $10,000; to manufacture electric motors, etc. Incorporators: W. K. Stanley, Samuel Horowitz, G. R. Brown, P. A. Prentice and J. R. Jewitt.

JEFFERSONVILLE—Jeffersonville Auto Co.; capital, $8,000; to deal in motor cars. Incorporators: W. W. Williams, F. E. Wilson, J. C. Creamer, G. E. Straley and M. F. Hudson.

SPENCER—Spencer Mfg. Co.; capital, $50,000; motor cars. Incorporators: C. R. Aldrich, J. J. Christy, J. H. Firestone, P. J. White and G. W. Hartman.

Oklahoma

OKLAHOMA CITY—Oklahoma Overland Motor Co.; capital, $20,000; to deal in motor cars. Incorporators: Sam Johnson, Edgar C. Johnson and J. Rooney, all of Oklahoma City.

Accessories for the Automobilist

OAKES Beartone Horn—A new horn has been brought out by the Oakes Co., Indianapolis, Ind., called the Beartone combination fan and horn. The horn, Fig. 1, is of the regulation diaphragm type and is mechanically operated. The diaphragm is fastened to the central portion of the cooling fan assembly and rotates with it. Inside of the fan support is placed a stationary piece which causes the diaphragm to vibrate when it is brought in contact with the latter. This stationary part is operated by a small lever shown at the back of the fan bracket. A button or small lever on the steering column is sufficient to operate the horn. The horn has several unique features. It cannot be operated by mischievous children when the car is standing if the motor is dead. The tone may be varied by the pressure of the button—strong on the country roads and low in the city.

Sly Tire Holder for Ford Cars—A tire holder, Fig. 2, combined with a lamp and license pad holder, and which is equipped with a lock has been announced by the New Era Spring & Specialty Co., Detroit, Mich., for Ford cars exclusively. The material is pressed steel. The license pad support is a cross piece at the top and the tail light support takes the form of an extension at one side. The attachment is simple and can be accomplished in a short time. No drilling is required as the device is held in place by clamps. The illustration shows rods running to the top holder, but this construction is not entirely necessary, as the concern supplies another means of attachment which fastens under the rear spring center bolt. For wire wheel carriers an offset cross piece is necessary to clear the wheel hub.

The price of the double holder for 30 by 3½ tires is $5, and for 31 by 4, $6, both being for rear attachment.

Beers Lantern—A lantern, Fig. 3, for use about the car has been brought out by the Beers Sales Co., Bridgeport, Conn. It uses a dry battery as its source of current and it is stated that it will give 50 hours of light on one cell, which costs approximately 25 cents. It sells for $2 with black rubber finish, $2.50 with polished brass and $3 with solid brass, nickel plated.

Van Sicklen Speed-Meter—Two speedometer models will be offered for 1915 by the Van Sicklen Co., Aurora, Ill. One of these is for cars in the Ford class and the other, Fig. 4, for larger cars. The former sells for $12 and the latter for $20. The Ford model is a bracket type and is adaptable to any machine with a 30-inch wheel. The larger model may be had in either flush or bracket designs and may be driven from the rear of the gearset or the front wheel, as desired.

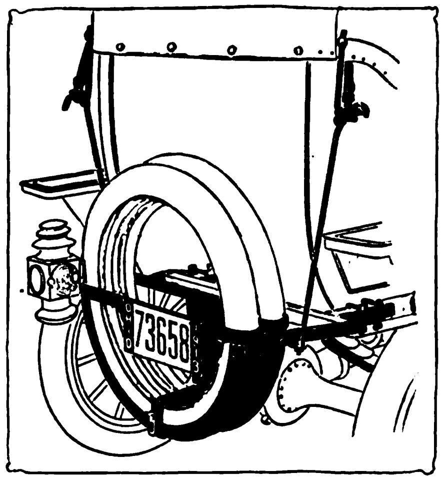

Fig. 2—Sly tire holder for Ford cars

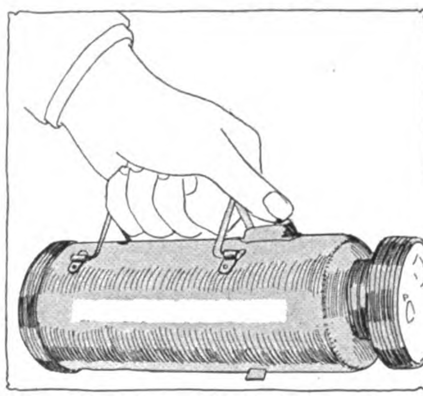

Fig. 3—Beers lantern which uses a dry cell

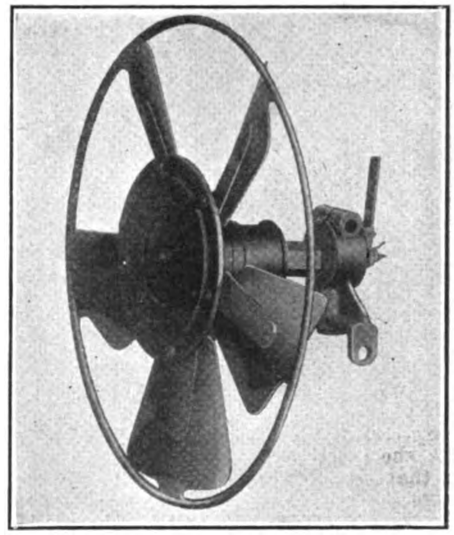

Fig. 1—Oakes Beartone fan horn

No mechanical changes have been made in the Van Sicklen, which operates by air, but several changes have been made in the exterior. The size of the figures on the dials has been increased and a broad collar has been added to the larger instrument which allows it to be mounted flush. The season odometer registers 100,000 miles and the trip 100 miles.

The feature of the new Ford design is the driving gears. Crown type gears are used and these allow perfect meshing even when the wheel is out of true. It is said that they will not clog with mud and will not rattle or grind.

Where the front universal is exposed, drive is taken from this point, a specially designed and deeply grooved hobbed pulley locking positively to the member to which it is applied. The hobbing in the drive and driven pulleys is of the same pitch as the coil of the endless wire belt used and allows no slippage, it is said.

Hoover Shock Absorbers—To meet the demand for a shock absorber for cars up to 1,500 pounds, the W. H. Hoover Co., New Berlin, Ohio, has put on the market the device shown in Fig. 5. It is similar to the ordinary Hoover shock absorber except that it is smaller and instead of a buckle the straps are held by a small bolt. The price per pair is $5. The leather straps are guaranteed not to be affected by heat, cold or moisture and are said to be very durable.

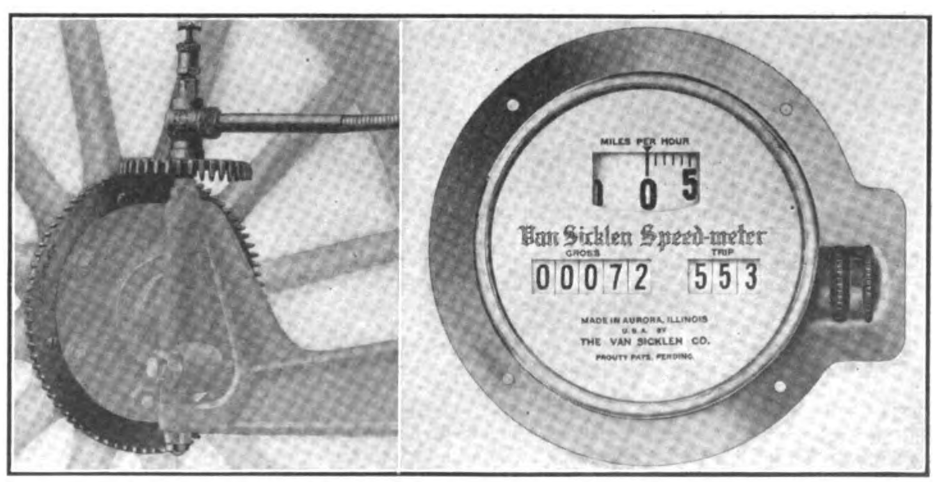

Fig. 4—Left—New Van Sicklen speedometer gear drive. Right—Flush type Van Sicklen speedometer

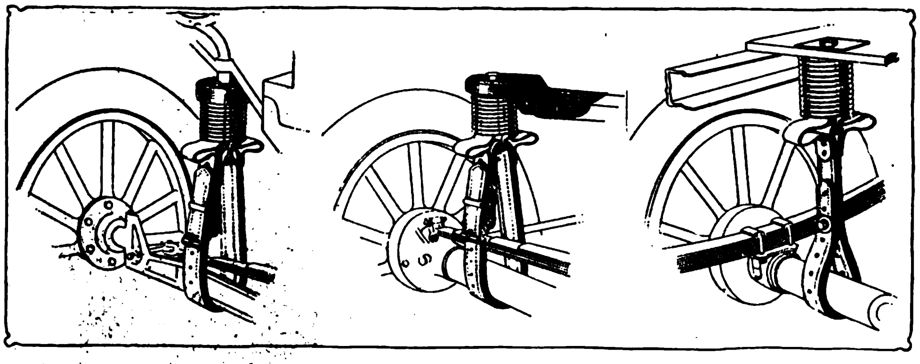

Fig. 5—Left—Hoover shock absorber for Ford cars showing special fittings to make attachment easy. Right—Shock absorber for cars up to 1,500 pounds

Special fittings are now furnished with the shock absorber made for Ford cars so that attachment is simplified. At the front the shock absorbers are attached to the lamp brackets and at the rear to the frame. These cost $7.

Sword Piston Ring Remover—A simple piston-ring remover which prevents breakage of the rings is being manufactured by the McKay-Lees Co., New Haven, Conn., and sold for $1. This tool, shown in Fig. 6, has two jaws at its end, these coming into engagement with the ends of the ring. Then by bringing the handles together the ring is spread so that it may be slipped over the piston.

Gray & Davis Ford Lamps Are Extra—In the description of the Gray & Davis starting and lighting system for Ford cars, appearing in THE AUTOMOBILE, November 5, pages 872 and 874, some readers gained the impression from the last paragraph that the electric head and tail lights were sold as a part of the complete equipment, which was not intended. The complete equipment, as stated, includes a dynamo, motor, 6-volt battery, wiring and the necessary connections. The lamps are extra.

Popp Co. to Market Welding Outfit—The M. L. Popp Auto Repair & Mfg. Co., 316 Thirteenth avenue, Milwaukee, Wis., has perfected a portable welding and cutting outfit of the oxy-acetylene type and is now arranging to market it. The outfit consists of a 40-gallon oxygen tank, a 3-gallon oxy-filter tank; an oxygen generator, gasoline furnace for heating the generator, and a Prest-O-Lite tank, the whole being mounted on a roller platform. The apparatus lists at from $45 to $125, depending upon size and capacity.

Vitalite Tires—Rubber tires which are guaranteed for 5,000 miles are made by the Vitalite Rubber Co., Woolworth Bldg., New York City. The particular feature which gives long life in this tire, it is claimed, is the vitalized rubber used in the tread. The tread stock is a compound from which nearly all the sulphur has been eliminated. This compound will vulcanize before the duck and friction are injured by the high heat.

Cutler-Hammer Dimming Switch—Fig. 7 shows a new headlight dimming switch with flush plate, developed by the Cutler-Hammer Mfg. Co., Milwaukee, Wis., and which supersedes this company's former combination of three gang switch used for series-parallel dimming control.

This new series-parallel switch is smaller and gives the two combinations as follows: Headlights bright and tail, and headlights dim and tail. Pulling out one button gives the dimmer combination, connecting the two headlights in series

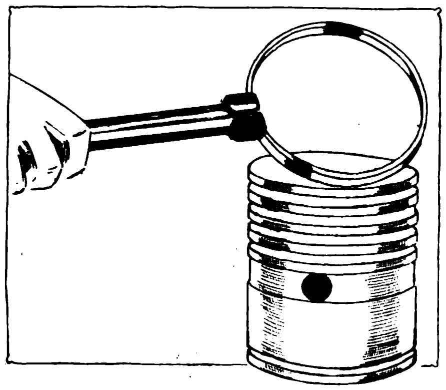

Fig. 5—Sword piston ring remover

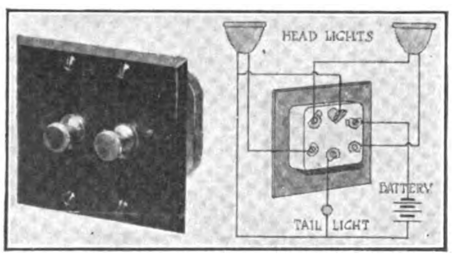

Fig. 7—Cutler-Hammer dimming switch

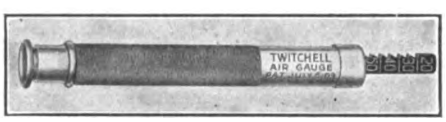

Fig. 8—Twitchell positive tire pressure gauge

and tail light individually across the battery or generator terminals. Pulling out the second button connects the two headlights in parallel, the tail light remaining connected as before.

This switch can be used on 6-volt circuits or on 12-volt, three-wire circuits using 6-volt lamps.

A quick-make and quick-break type mechanism is used and easily wired cupped washers are provided for making the terminal connections on the rear. The cupped washers prevent vibration from loosening the connections and where stranded wire is used all strands are held permanently in place. The switch mechanism is enclosed in a dustproof metal case and terminal connectors are mounted on a quarter-inch block of Pyroplax—a fireproof insulator.

Flush plates can be furnished in a number of finishes. The plate in the illustration is dull black which has proven a very popular finish. When the push-and-pull buttons are in the normal position, as shown, the switch is open. To close the circuits the buttons are pulled out. There is no danger of running down the battery by accidentally closing the circuit in the daytime when the lighted lamps would not be noticed. The position of the button, whether in or out, can be readily detected by the fingers alone when the switch is installed out of sight. Where desired this new series-parallel switch can be connected with other switches controlling side lights, speedometer and license lights.

Twitchell Tire Gauge—The new gauge, Fig. 8, made by the Twitchell Gauge Co., 1200 Michigan avenue, Chicago, Ill., has an indicator bar which automatically locks at any point of pressure, making inaccurate reading impossible. The gauge is very simple, consisting merely of a leather packed plunger attached to the indicator bar and moving in a small metal cylinder. The outward movement of the plunger is resisted by a coil spring. When this gauge is placed over the valve stem of the tire the piston is forced out and the rod indicates the correct pressure, the rod being held in this position by saw-tooth notches which catch in the edge of the casing. After the pressure has been read, the tooth of the indicating rod which is holding it in place is pushed out of engagement and the rod flies back. The gauge is guaranteed for 1 year and sells for $1. It is easily read because the figures are large and white on a black background. On account of its peculiar base the new valve may be held at any angle. In the dark it may be read by counting the notches.

Hoyt Pocket Multimeter—A new instrument, Fig. 9, comprising a voltmeter and ammeter in a single case, the face of the ammeter being on one side and that of the voltmeter on the other, has been announced by the Hoyt Electrical Instrument Works, Penacook, N. H. The whole device is only 2¼ inches in diameter and 1¼ inches thick, and it permits of both voltage and current measurements being made simultaneously but without the trouble of two instruments.

The instrument is of the moving coil type, jewel bearings being used. The prices vary from $10 for the 10-volt, 15-ampere type to $24 for the 40-volt, 40-ampere type. Practically all ranges and combinations may be had.

VOL. XXXI NEW YORK—THURSDAY, NOVEMBER 26, 1914—CHICAGO No. 22

The AUTOMOBILE

Army automobiles and Belgian refugees on the main road into France not far from the scene of actual fighting

On the Belgian Frontier

Military Cars and Trucks in Endless Lines—Private Traffic Abolished—Rigid Regulations—Ruined Roads

By W. F. Bradley
Special Representative of THE AUTOMOBILE
with the Allied Armies in France

ON THE BELGIAN FRONTIER, Nov. 5—Over deserted highways we sped through Normandy, charmingly beautiful in its autumnal cloak. Automobiles are too useful to be allowed to expend their engeries haphazard; they are too dangerous to be given full liberty.

The military authorities have sought to abolish all private automobile traffic, and as ours was a civilian mission we had first of all to be put through the double sieve of a military and civil interrogation. When the police inspector ushered us out of his private office the little he did not know about us was hardly worth knowing. But this was not sufficient to give us the freedom of the road. Two hours later we had to appear, hat in hand, before a military board of five officers who questioned and cross questioned us as if anxious to worm out some of the hidden secrets of our lives. Then were we free to travel over some of the deserted highways of France.

The author, W. F. Bradley, driving a Belgian officer near the firing line

Train Service Off

Motors are not the only restricted means of locomotion. When the train service is needed by the army the public has to wait—or walk. Thus, in a certain quiet township a farmer begged a lift to his home 20 miles away. When we had been assured that there were no military posts on this portion of the road, he was taken aboard. He got out on the outskirts of the town, so as to avoid passing before the guards, for however honorable he might be, it was forbidden for him to ride in a car without a special military permit. In half an hour he had covered a dis-

At the left are shown some of the French and Belgian soldiers on the road near Furnes, Belgium, near the firing line

At the right is a German automobile wrecked by Belgians on the canal side near Dixmude

Below is shown one of the Red Cross motor ambulances after it was struck by a shell

tance which would have necessitated 6 or 7 hours steady tramping. At a railroad grade crossing we came upon the cause of the suppression of his ordinary means of travel: a troop train, drawn by two powerful American engines, and carrying English horses and men to be flung into the great battle line on the northeast frontier.

At nightfall shelter was sought in a second-rate hotel of a small French town. The law forbade us as civilians to travel after sundown. The occupants of three military cars dined, lit their lamps and went forth into the darkness while we climbed a narrow staircase to an old-fashioned bedroom.

War's Miseries

Poets sing of the glory of war; travelers along the highroads see little but its misery. Climbing a hill into a big village square we came upon hundreds of refugees and scores of long, lumbering farm wagons filled with household goods, old men and women and children. They were Belgian peasants who had fled from their quiet farms and peaceful villages as the German hordes swept in.

There were few valid men among them, for the army had claimed them. They told pitiful tales of their houses razed before their eyes, their cattle driven away, members of their community driven off as hostages, of long marching, of nights spent in barns, or sleeping in their wagons by the roadside. French gendarmes had taken in hand these human derelicts and were passing them on from town to town to districts where they could find employment and the necessaries of life.

Devious Routes Followed

By devious routes, so as to avoid the main roads which might have been congested with army convoys, we worked our way towards that northeast corner of France where British, French and Belgians were endeavoring to drive back the innumerable forces of Germany. A village street was filled with women wending their way to church; they were all in deep mourning and not a man among them. There were more villages, deserted by all but women and children; valleys and hillsides were as quiet as the grave. Of military preparations there was not a sign.

Into the War Zone

Suddenly, from a thicket by the roadside a soldier stepped forth, raising his rifle with a meaning that could not be mistaken. We had entered the area occupied by the French and Belgian armies. The pass was examined carefully, the photographs it bore being compared with our features before we were allowed to pass into the war area. At various intervals, which might be from .5 to 3 miles, the same operation was gone through. French soldiers gave way to Belgian guards, then to Frenchmen, then again to Belgians. We were in the level dyke country, cut up with canals along which clumsy barges were towed by men and sometimes by mere girls. The roads were crowded with Belgian soldiers—the remnants of a gallant army which had been sent to the rear to reform for more desperate resistance.

The Three Armies

We had plenty of opportunities of judging the temper of the three nations united in their stand against the forces of the Fatherland. The English were authoritative, their officers haughty; the French were suspicious, their officers studiously correct; the Belgians were kindly, their officers hearty.

At one of the posts Belgian soldiers barred our path. The sergeant in command frankly stated that he was not satisfied as to our right to be in the military area; but he put his objections in such a gentlemanly manner, he was so courteous, that it was a pleasure rather than otherwise to be questioned by him.

10 Days in the Trenches

A few miles further on, at a turn of the road where our direction seemed doubtful, we came upon a group of four Belgian soldiers and two gendarmes. Two of the men being sick, we offered them a seat in the car, and at the same time took over the rifles and kit of the others, promising to deposit all at the next village. After 10 days in the trenches, without being able to lie down to sleep, never a wash, with food passed on to them at night, our two passengers looked more like scarecrows than soldiers. They were both volunteers, mere youths, whose homes had been wrecked, whose parents had been scattered, and who were fighting with the desperation of men who had nothing more to lose and everything to gain.

War's Steel Bands

Travelers, whether on foot, drawn by horses or propelled by gasoline, could not get into the important frontier town of A— until they had been individually examined. To get out again was even more difficult and probably we should have been there still had it not been for the kindly intervention of the Belgian authorities who gave all necessary passes to travel through the small portion of their territory still withheld from the enemy.

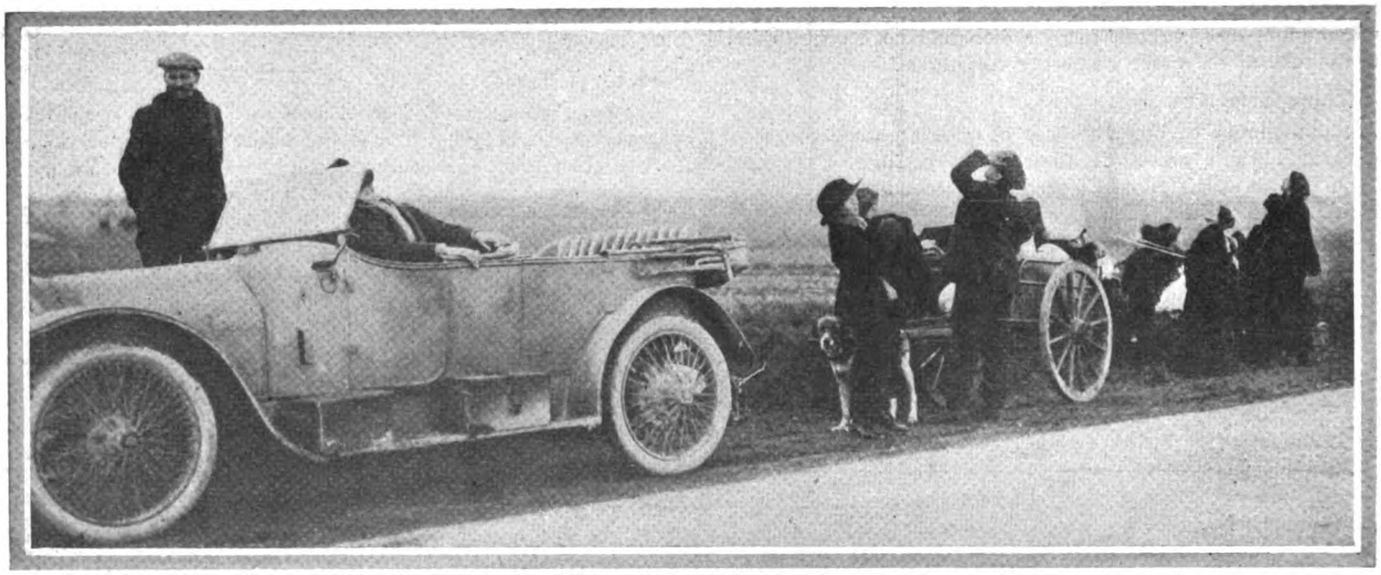
The Ruined Road

It was a Sunday afternoon. On the immediate outskirts of the fortified town well dressed burghers were making a pious pilgrimage to the cemtery and were depositing wreaths in memory of many who lay in unknown graves. To the

Above is illustrated a Belgian signalling car and German bicycles abandoned in the battle of the Yser

At the left a scene on the road outside Furnes. The Belgians have a little lamb

Left—A Belgian armored car on the battlefield near Ypres, Belgium. Right—A Belgian armored car in the battle of Yser



Belgian refugees on the road from Furnes to Dunkirk, watching a German aeroplane maneuvering above the frontier

northeast the steady boom of the cannon could be heard. On the main road running by the side of the canal there was such a variegated collection of human beings, of animals, of vehicles, of material, as only war can produce. It had once been a well-kept highway. But war material had rumbled along it, thousands of hoofs had loosened its surface, thousands of feet had trampled it into a bed of mud. Along the center the going was fairly good, but this passage was barely sufficient for two cars, and on each side were mud bands with holes from a few inches to a few feet deep.

Endless War Line

The procession of military automobiles was unending. As they passed one another they skidded and swerved in the mud baths, rocked ominously, but kept on their course. The war found Belgium without any great number of motor trucks, but with a good stock of touring cars. These machines have been taken and put to the most widely different tasks. Handsome limousines built by Van den Plas and D'Iteren carried staff officers; equally handsome cars were filled with raw meat, packed to the roof with bread loaves, carried fodder for the horses, saddles, ammunition, oil and gasoline—everything which can be useful in war.

A wayside meeting—French and Belgian soldiers chatting with the representative of THE AUTOMOBILE

Take the automobiles on Fifth avenue, New York, when traffic is most intense, leave a few of the best cars untouched, set a band of ruffians to work on the others, bespattering them with mud, breaking the lamps, smashing the mudguards, tearing the hoods, delving the panels, smearing the upholstery, and you will have some idea of the state of the cars used in the Belgian army.

Such a condition of affairs is only a natural consequence when one considers the fact that these cars and trucks are most often driven by men who are not only unfamiliar with the construction and operation of the vehicles they are called upon to handle but many of whom are volunteers absolutely without experience in work of this character. It is greatly to be regretted that such is the case as there are plenty of men shouldering rifles, digging trenches, etc., who have had ample experience which is now absolutely wasted. The British army has attacked the problem in a more systematic way with the result that its motor transportation is much more efficient and much less wastefully administered than is the case in the other armies.

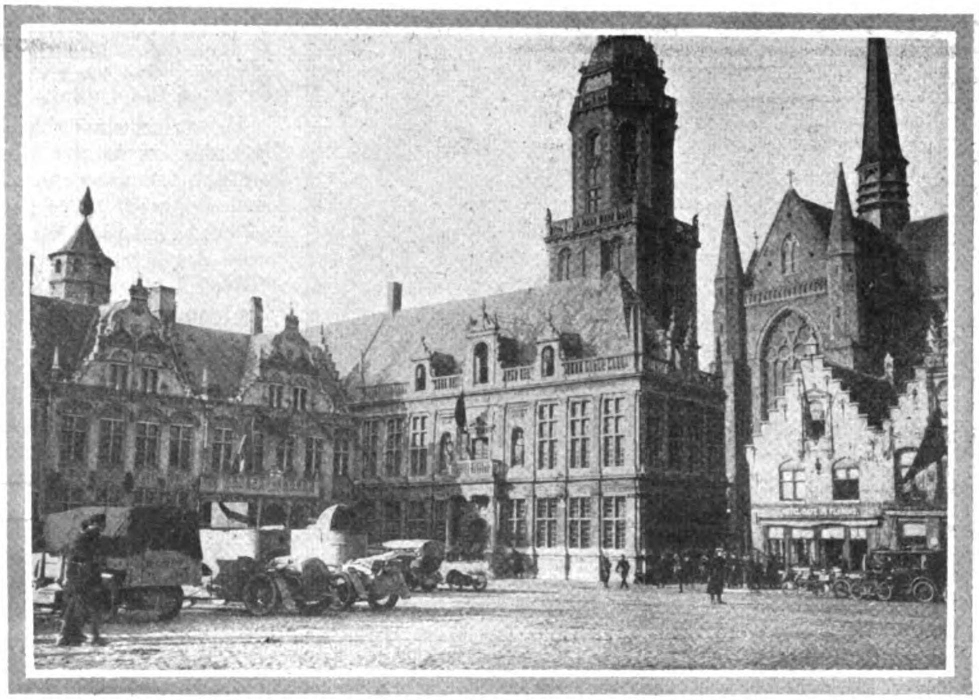
American Cars Used

Evidently the Belgian supply of cars has not been sufficient for the army's needs, for dozens of Overlands were noted in the convoys, occasionally a Maxwell was seen and staff officers occupied a Packard. It is obvious that touring cars are not the best vehicles for the various services to which they were put, but it was remarkable to note with what success the cars built for passenger carrying work were doing duties as varied as carrying King Albert and transporting barbed wire to the front.

England, France and Germany have special types of cars for special kinds of work, each machine being the result of careful thought and study. Belgium, plunged into a defensive war with no warning and little preparation, has had to rely on her touring cars —and has reason to be proud of them. King Albert's army has lost most of its cavalry, it has few transport horses, but it is feeding itself and moving itself in a wonderful manner by means of touring cars.

Belgian Armored Cars

There is another use to which the Belgians have put their more powerful touring car chassis. Minervas, Savas, Excelsiors and Pipes, in particular, have been fitted with a machine gun and armor plating, and have done excellent service in the recent operations. There is nothing at all special about the chassis, and even the armor plating is not a difficult matter. Steel plates of not less than 5 millimeters thickness are built around the chassis, forming a single compartment in the center of which the gun is pivoted. In some cases a revolving turret is fitted, while others merely have a shield in front of the gun, and of course revolving with it. The driver occupies the most central position in the machine and is practically immune from attack except on the complete destruction of the vehicle. He has a view straight ahead through a hinged shutter and in addition has a small port on the right, level with his head.



A scene on the historic market place at Furnes while the Belgians were in possession

In Bombarded Town

Germans were bombarding the town of Furnes when we ran onto the beautiful and historic marketplace. It was a curious situation; the weather was ideal; the big square was filled with armored cars, touring cars, and light trucks; French and Belgian soldiers marched through from time to time; officers came and went in cars; American and English newspapermen, driven out by the French and English, found shelter in the Belgian town and marched up and down with camera in hand; refugees with their scanty belongings on bicycles, on wheelbarrows, on frail carts drawn by a dog or a donkey, hastened westward; idlers stood at the street corners—and suddenly a shell burst over the town, coming from nobody knew where.

King Under Fire

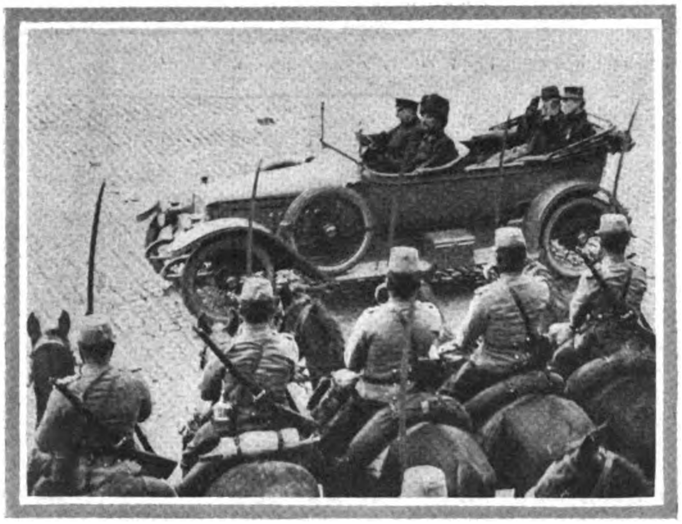
The aim was indifferent for a couple of hours; then the Germans seemed to get the range, for a shell fell on the roof of one of the houses, within 20 yards of where King Albert was standing.

At the top of the tower, built in 1628, and which was being used by the Germans as a target, observers finally got the location of the battery. A force was sent out and within a couple of hours the guns had been silenced and sixty German prisoners were being marched across the square escorted by Algerian cavalry. The guns had been hidden in a farm when the enemy was forced to retreat and a small force had moved forward to operate them until ammunition was exhausted. The soldiers were captured and the civilians who had allowed the farm to be used were shot.

The Retreat

As evening closed in we ran back to French territory over a road blocked with every kind of traffic. Belgian artillery was being sent to the rear, and hundreds of refugees were taking advantage of the gun carriages to set their various bundles on them and walk by their side. Every class of society was represented, from the peasant in rough sabots carrying some clothing tied in a dirty bed sheet, to the comfortable bourgeoise in furs and jewelry. There was no

Moving forward—Belgian automobilists and cyclists on the main road to Ypres in the forward movement of the Allied armies



President Poincairé and the King of Belgium reviewing the Franco-Belgian Army

whining or complaining. A man with a big black trunk on a wheelbarrow, his wife bending under a heavy bundle, and each of his four children carrying some domestic article, stopped to relate to a group of soldiers how he had decided to move when a shot had gone right through his house.

Injured Cars and Trucks

French long range artillery moved forward at a brisk trot, accompanied by their ammunition wagons surmounted by jet-black African soldiers who looked cleaner than most of the Europeans and certainly displayed more boyish glee. A wrecked German touring car lay directly across the bank with its radiator but a couple of feet from the canal. It had attempted the previous evening to get through to French territory. One of the new French four-wheel-drive tractors had taken fire and was being stripped by the mechanics of all the parts which might serve for companion machines. Cattle were being driven rearwards by Belgian soldiers who advised the motorists to "charge right in at them." In the country left and right of the road barbed wire obstructions had been erected, there were deep trenches behind, then further to the rear more trenches completely covered over.

Sleeping is always a delicate problem at the front. After some difficulty we discovered an attic with two beds in it, a window about a foot square and a roof so low that we could hardly stand upright. The furniture consisted of a broken chair and a dirty comb. As we examined it dubiously the landlady remarked, "Can't you be satisfied with one of the beds?"

All Cars Confiscated

During the night an order was posted in that town that all automobiles, of whatever kind, and without a single exception, must be presented to the gendarmes within 24 hours, under pain of confiscation. We decided to flee from that town. But there was no gasoline to be obtained. Without any warning the military authorities had confiscated the entire stock. After a thorough search we were able to pick up a gallon which a garage proprietor declared he had found in a touring car and to discover a gallon of benzol at a grocery store.

Just after crossing the frontier station into Belgium there was an imperative shriek from a Klaxon and a dozen handsome cars came round a bend of the road at a fast clip, driving all other users into the muddy side tracks. The cars carried King Albert of Belgium, President Poincairé, the French and Belgian ministers of war, Lord Kitchener and staff officers of the various armies. Shells had ceased falling at Furnes but were coming down 5 miles to the east. Even this was sufficient to bring many of the peasants back again to their fields and their houses.

Deserted Caterpillar

It was reported that the road was cut up by shells, so we left the car in the village apple market and moved ahead on foot, following the coast road, the possession of which was still disputed. Wreckage was plentiful. By the side of a cobble paved road lay a German motor truck which had been used for bringing infantry forward. In one of the partly flooded fields was a German caterpillar tractor used for hauling guns across country. It was of the same type as some of the machines used by the French farmers for plowing. The Belgians had opened their dykes and even the caterpillar had become embedded in the mud.

The hiss and clap of shells greeted us at frequent intervals, but such is modern war that there was nothing to indicate where they were coming from or what they were being fired at. When the branches of trees began to fall 30 yards away we thought it best to retire.

While we were doing so some of the famous French heavy artillery came up drawn by their four-wheel-drive gasoline tractors only introduced about a year ago. A couple of miles further back a score of Paris motor buses rumbled past, each one carrying forty men. Running past one of the French encampments near the Franco-Belgian frontier, we had an example of the extreme mobility made possible by the use of automobiles. A driver hailed us and proved to be a friend in the automobile business. Two days before he had been at the other end of the battle line, 200 miles away. Reinforcements were required at the North sea end and within an hour hundreds of cars and trucks had been sent out with officers, men, guns and ammunition.

The Rescue

The gasoline problem was becoming acute when luck intervened. A Belgian officer approached the group of which we formed a part and asked if any car was going back into French territory. We seized the opportunity, volunteering not only to carry him into France but to his final destination, about 50 miles away. With a military order the gasoline was forthcoming immediately, and in much less than 2 hours we had brought the captain a distance which it would have required 10 or 12 hours to cover by train.

It takes little to disorganize a railroad, while it is practically impossible to disorganize an automobile service.

That run gave us an opportunity to examine some of the London motorbuses in war paint. Daily newspapers long

Belgian cyclists resting on the roadside in their advance on the German lines ago worked up the story of a Hendon bus going into action with its "Glad Eye," "Come over Here," and other advertisement signs. Unfortunately for the newspaper men, the stories were released before the buses had got across the Channel. When they did come over they were hardly recognizable, for every word of advertising matter had been removed, they had been painted in a dull gray, the windows had been replaced by boarding, and the only decoration was a bouquet of flowers hung up by some Tommy where the service number usually appeared.

Automobile Corps for Canadian Guards

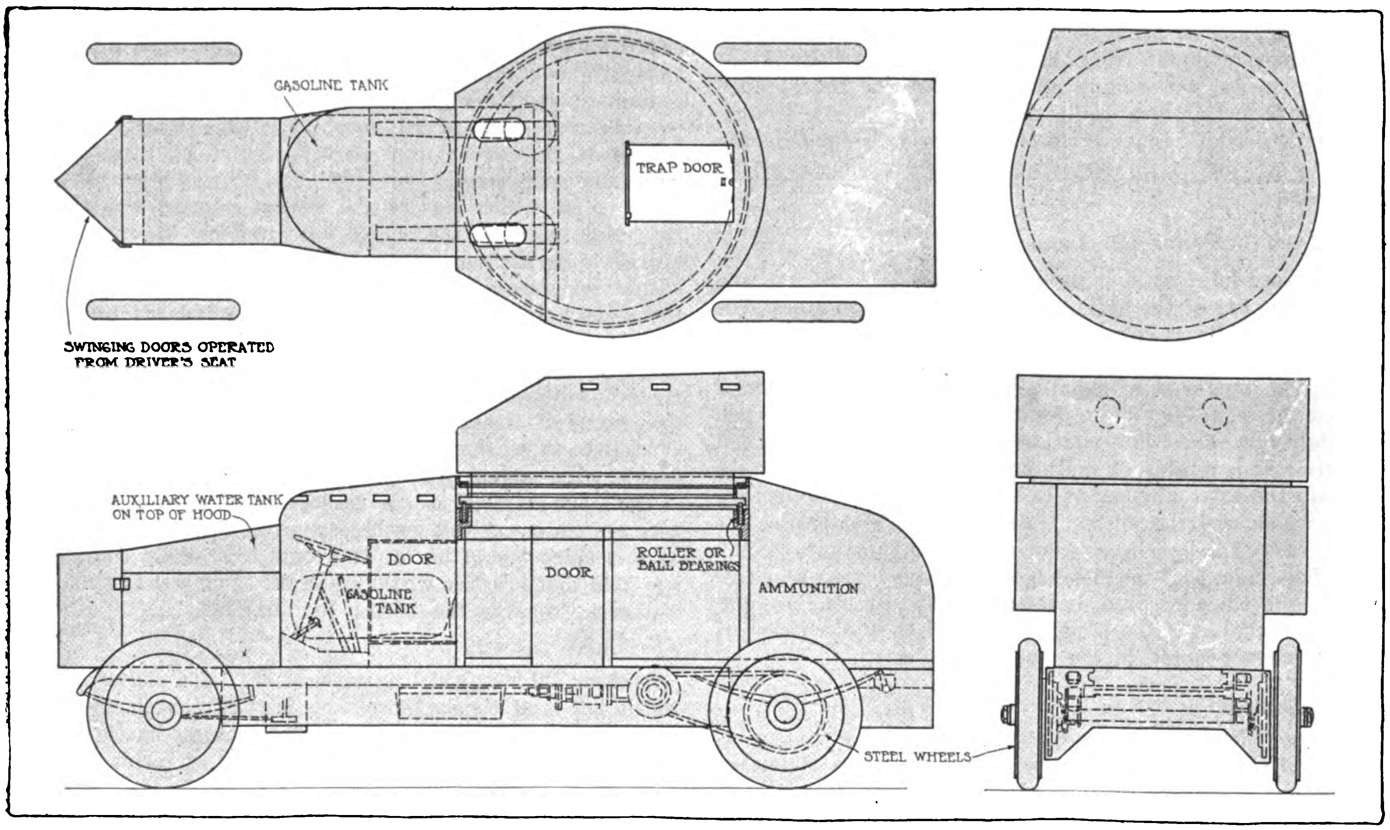
MONTREAL, QUE., Nov. 20—More than 1,000 automobiles are to be equipped by the Automobile Club of Canada to form a battalion in conjunction with the Home Guard. The club, taking into consideration the prominent part that automobiles have played in the war, yesterday proposed to J. N. Greenshields, chairman of the organization committee of the Home Guards, the formation of such a corps in the Province of Quebec. The committee, formed of H. W. Pillow, president of the club, Eugene Tarte, vice-president and A. McNamee, secretary, had an interview with Mr. Greenshields yesterday, and their proposition was enthusiastically received. A number of automobile owners of this city have already offered the use of their cars, and have also promised to equip them with machine guns, ammunition, medical apparatus or other supplies.

Ready for Border Raid

It is thought that with a thousand cars, the Home Guard could be transferred rapidly to any point at which the enemy might appear in force, especially should a raid be attempted from across the border. Plans have already been prepared for any contingency of this nature, although, naturally, they will not be made public. The directors of the club expect that their call will be met with a prompt answer from automobile owners in the city, and that by the end of the week the total number of cars registered will be over 1,000, ready for any emergency.

That aliens of enemy nationality who are to be interned as prisoners of war in Canada, should be put to work, breaking stones or doing other things necessary for building good roads was the suggestion made to General Hughes by an Ottawa delegation representing the Motor Assn. The suggestion was favorably received, but a definite answer was not given. The whole plan of what to do with such people is being reported on by General Otter.

An Armored Truck with Revolving Gun-Turret



As reported in THE AUTOMOBILE *for November* 19, *the Armored Motor Car Corp. has been organized and incorporated in New York City for the purpose of producing an armored truck mounting two machine guns in a revolving turret. The illustration gives a side elevation, plan and rear views of the truck and a plan of the turret, showing the various constructional features.*

J. H. Allen, organizer of the concern, has a patent pending covering the application of a revolving turret to a motor truck. The steel bodies will be built on contract and mounted on 2-ton Federal chassis. The two guns which are to be mounted will probably be Maxims firing 600 *shots per minute.*

Mr. Allen, in speaking of the field for such an armored truck, pointed out that under modern war conditions cavalry forces are practically useless for actual work on the battlefield or in reconnoitering under fire, as they are unable to withstand the terrible effects of high-power artillery and rifles. On the other hand, an armored car could not only pass practically unscathed through a withering rain of rifle bullets, etc., but could also do great execution with its machine guns. The revolving feature of the turret permits the fire of these guns to be directed against the enemy, irrespective of the direction in which the truck is traveling. The radiator is protected by swinging doors of armor plate.

Eight Cylinders Analyzed by S.A.E.

Nine Reasons for Success Advanced in Paper by D. McCall White—Standards Committee Hears Division Reports

NEW YORK CITY, Nov. 24—At the meeting of the Metropolitan. Section of the Society of Automobile Engineers held here tonight D. McCall White, of the Cadillac company read a paper on the high-speed, high-efficiency, eight-cylinder V-type engine. In it he divides cars into two classes, those used as a means of locomotion and those in which comfort and pleasure are as great in importance as infallibility.

Nine requirements of a successful design are advanced by the author; size, proportion, cooling, carburetion, lubrication, accessibility, simplicity, durability and manufacturing possibilities.

As regards size the eight is compared favorably with the four. The length is stated to be the same and the width but 2 inches greater. When these proportions hold true the power of the eight is 70 against 50 for the four. For the same power 50 per cent. more length is said to be needed for the six. The weight of the Cadillac eight is given as 50 pounds less than the previous four.

Better cooling efficiency is claimed because the distance of the rearmost cylinder from the radiator is less than in the six, thus giving the cooling advantages of the four. Each block of four cylinders is handled separately. As regards carburetion, one carbureter is claimed to give equal distribution when placed in the V, midway of the length of the cylinders.

Force Feed for Bearing Surfaces

Force-feed lubrication is used for all bearing surfaces and the average life of the bearings is given as 30,000 miles. The same accessibility is offered as for the four, all ordinary fittings and adjustments being reached by simply raising the hood. The argument of simplicity which has been advanced against the eight Mr. White disposes of by stating that when roadability is taken into consideration the difference is not material; and, insofar as main bearings are concerned there are only the same number as in a four. Durability depends on vibration and the author claims that in eliminating the latter, long life has been secured. As for manufacturing costs, he admits that the six is less expensive but as an offset mentions the cheaper crankshafts, camshafts, etc., on the eight.

The remainder of the paper is devoted to a discussion of the practices adopted in the Cadillac eight.

Paper Discussed

R. McA. Lloyd opened the discussion by stating that in his belief the Cadillac eight is a step in advance in American engineering practice. He pointed out that in this motor only 4 cubic inches per horsepower are used against 7 or 8 heretofore. But Mr. Lloyd doubted the necessity of such an amount of power.

Regarding gasoline economy, Mr. White stated that he had secured as high as 22 miles to the gallon with the eight and that it seemed to be better in this respect than the four.

A. F. Masury of the International Motor Co., who has had some experience in the manufacture of eights said that he believed difficulties might be found in the want of intelligent handling of the eight in the repair shop by men who were unfamiliar with the timing, etc. Henry M. Crane of the Crane Motor Car Co. expressed himself as not sure that the European trend of motor design is best.

In response to questions put by various members, Mr. White stated that the weight of the reciprocating parts was less than in a four of corresponding displacement, that the balance in practice worked out to the almost total elimination of vibration and the corresponding life of the motor was thereby increased.

The discussion was closed by David Beecroft who pointed out the broader meaning of the field of the eight. He stated that he did not feel that there should be a landslide towards the eight. but that it would be always with us to fill its particular niche in the industry, just as the four would fill its place.

Fourteen Divisions Report at Standards Convention

NEW YORK CITY, Nov. 19—Materially advancing the standards work which will be reported to the meeting of the Society of Automobile Engineers at their winter session in January, the standards committee 3-day convention closed here today. During the meeting the reports of fourteen divisions were heard and seventy-six members of the committee registered at the S. A. E. headquarters. The meeting was open to all members of the society and the standards discussions were participated in by them as well as by the committee.

The topic which was of the utmost interest was that of the single wire vs. the double wire systems for use in connection with electric starting and lighting installations. It will be remembered that at the summer meeting at Cape May the society as a whole as well as the standards committee was deadlocked regarding the advisability of advancing the single wire installation with grounded return as recommended practice. This discussion was again taken up and the results of investigation made by the division showed that more than twice the number of cars that are fitted with the double wire system will have a grounded return. In view of the large majority of car makers which favored the single wire system it was felt by the committee that the best method of procedure would be to let events take their course. It was held that practice would reach the same end as standardization as regards the wiring installations.

Headlights Discussed

Another subject, which in view of the wide discussion and legislation is of timely interest, is that of non-glaring headlights. The division dealing with this subject has appointed a sub-committee to investigate the opinions of various municipal and state authorities as to what constitutes glare. It was felt that in view of the chaotic difference of opinion which now prevails it would be far more wise to really determine what were the objectionable features of the so-called glaring headlights before attempting to adopt means of eliminating the rather vague quality of glare.

In the opinion of the division there are at present three successful methods of reducing glare. These three methods have been taken from the basic ideas of the various devices which have been presented to the society for testing purposes at the various section meetings and also those which have been widely advertised. Probably the most prominent of these methods is that in which the light is streamed so that the intensity of the rays is diminished either altogether or in the line of direct vision. Again there is the method of reducing the amount of illumination by some such means as double bulbs, a resistance in the lighting circuit or series-parallel switches. The third method is that in which the light is deflected without affecting the total number of illuminating units.

Measuring Glare

It is the intention of this division to work towards a standard method of determining the quantity of glare. It has been reasoned that if it would be possible to standardize a method of measuring the amount of glare upon some standard form of lighting diagram, it would be possible to measure all lights according to this diagram and then ultimately to incorporate the legal amount of permissible glare in the laws dealing with this subject. This would give a definite standard to which lamp manufacturers could work and would also tend to form a desirable uniformity in lamp legislation.

Another suggestion of this division is in the nature of the nomenclature of lamp parts. To avoid the confusion which undoubtedly exists between the terms lamp and bulb the division proposes the following definitions:

Bulb—That part of the detachable electric light-giving unit comprised of a filament and its glass envelope and base.

Lamp—The fixture for mounting and utilizing the light of the bulb.

The work of reducing tire sizes was also continued at the meeting. The pleasure car wheel division submitted a report at the last summer meeting in Cape May in which the number of tire sizes was cut to eight regular sizes. It was suggested that the 36 x 5 size be added to the list and considerable discussion hinged upon this point. The matter was finally dropped and will be brought up again for discussion at the winter session. The stumbling block that the division has now discovered on this part of the work is whether or not the oversize tires should also be published in the list of standard tire sizes.

It was argued that the ordinary sizes are proper for all ordinary purposes and that the oversize is only required where some exceptional work is anticipated. Some of the members of the committee on this account took the stand that the makers would begin fitting these tires as regular equipment owing to the fact that they could procure them in quantities almost as cheaply as they could the smaller size and this would deprive the purchaser of his option of larger tires. The bad result of this is that it would force the user to use larger tires than he needed for ordinary work with the resulting poor efficiency in gasoline consumption and to waste power in driving the heavier wheels without gaining additional benefit.

Standardize Inflation

The pleasure car wheels division is going to have something to say in a short time on tire inflations. A standard table of inflations for tires of different sizes will be adopted and in this table will be given what the committee deems the desirable inflation for all-around work. While the table has been compiled it is still under consideration and will not be acted on at present. The tire sizes that the division is now working on are as follows:

SIZE	OVERSIZE	SIZE	OVERSIZE
30 x 3	31 x 3½	34 x 4	35 x 4½
30 x 3½	31 x 4	34 x 4½	35 x 5
32 x 3½	33 x 4	36 x 4½	37 x 5
32 x 4	33 x 4½	38 x 5½	39 x 6

In addition to these there is a 36 by 5 with the 37 by 5 1-2 oversize which has not yet been agreed upon.

Considerable attention was given to the tires for commercial vehicles. Owing to the fact that wheel trouble has been experienced by commercial car makers it has been found necessary to alter the dimensions of S. A. E. felloe bands. The discussion brought out that a number of makers felt that the trouble was due to the thin band which offered insufficient support for the wooden felloe. An increase in the band of from .25 to .375 inch was considered desirable.

The discussion which followed this suggestion brought out that in the larger tires, for instance where 6-inch dual tires and over are used there is some question as to the advisability of increasing the thickness of the felloe bands as much as 1-2 inch. The amount of metal which it would be necessary to add in order to effect this change would so seriously increase the weight and the cost of manufacture that it would be almost as cheap to buy an entire metal wheel instead. The discussion hinged about the technicalities of wood wheel manufacture and brought out that there are often imperfections in the design and manufacture of these wheels. The point at which fault was found was in the bad connection between the spoke and felloe band. In order to make a proper connection at this point the spoke should be flared in order to cut down the amount of unsupported overhang.

The electric vehicle division is now operating in conjunction with the Electric Vehicle Assn. of America. The work upon which the joint committee is engaged has centered itself particularly along the line of proposed standards for electric motors of 60 and 80 volts. When the work is complete it is proposed not only to give the standard dimensions of these motors but also to issue charts showing the electrical characteristics of the motors.

The matter of electric vehicle speed and mileage ratings was also gone into by the electric vehicle division. Two standards were recommended in conjunction with these ratings. That on speed states that the rating shall be based on continuous operation with one-half load over hard even and level roads or pavements at the actual average of battery voltage. The rating covering mileage states that it shall be based on the rated 5-hour discharge capacity of the battery and the continuous run under the same conditions as those laid down for the speed test, that is, one-half load over hard roads at the actual average battery voltage.

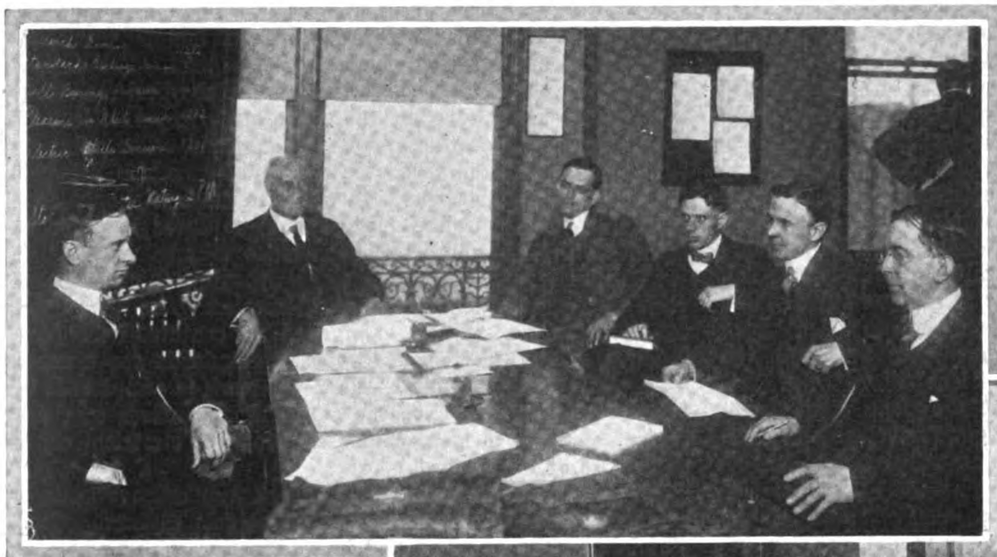
Exchanging Standards

A phase of the standards committee work which has made gratifying progress is that taken in hand by the standards exchange division. This newly appointed committee which has for its object a harmonizing of S. A. E. standards with those of other engineering bodies, has announced that the American society for testing materials had created an automobile steels committee which had under consideration the adoption of the entire list of S. A. E. steels as they stand. The same progress is being made in the way of spring steels.

A useful feature in the work of the standards exchange division is that in connection with unit power plant. The division is studying the shapes and dimensions of the bell housings used by motor and gearbox manufacturers with a view towards adopting standards so that it will be possible to connect any make of gearbox with any make of motor. If this could be effected it would be a boon to the manufacturers of assembled cars because it would enable them to secure parts and avoid delays which frequently occur in the delivery from other than the usual factories in case of an unexpected demand for particular units.

J. M. Hill, representing the promotion interests of the Panama Pacific Exposition in San Francisco attended the standards committee meeting for the purpose of pointing out the importance of having the Society of Automobile Engineers well represented at the coming exposition. He particularly emphasized the need of having competent automobile engineers to supervise the work of erecting the buildings, etc., to be used in connection with the housing of the exhibits and tests. It will be remembered that at the summer meeting it did not seem probable that a majority of the members would favor a meeting of the society next summer on the Pacific Coast. The reason which appeared to be advanced was that there would not be as good an attendance as would be the case were the meeting held in the middle west.

S.A.E. Standards Men in Session



Left—Research Division, Left to Right—D. L. Gallup, R. C. Carpenter, J. A. Moyer, C. B. Veal, D. Roesch, W. T. Fishleigh

Right—Spring Division, Left to Right—W. T. Norton, Jr., W. M. Newkirk, J. G. Utz, C. E. Clemens, R. L. Morgan

Canadian-American Firms to Make 36,000 Cars in 1915

Six Plants of This Character Now Operating, One Being a Truck Firm—Other Plants in Preparation—Large Proportion of Output Exported—Liberal Inducements for Plants

DETROIT, MICH., Nov. 2—Thirty-six thousand automobiles will be made in 1915 in the Dominion of Canada by Canadian-American automobile manufacturing concerns, or Canadian companies building or assembling cars of American origin.

Six Canadian-American Plants

There are now only six automobile manufacturing concerns in Canada which make or assemble American cars, or cars having an American name. These concerns are the Ford, Studebaker, Reo, McLaughlin-Buick, Hupp and Gramm companies.

The R-C-H, Olds and Keeton plants have been discontinued. The plants of the Willys-Overland and Regal companies are not yet in operation. The Maxwell company has only general headquarters in Canada for distributing purposes.

Of the six concerns making or assembling cars, the Ford Motor Co. of Canada, Ltd., Ford, Ont., is by far the biggest. While during 1914 the total production will be 18,000 cars, the schedule for 1915 calls for 30,000. About 1,400 is the average number of men employed, but, this year, owing to the war, only 800 are on the payroll.

Established in 1904 with a capital stock of $125,000 fully paid up, this capitalization has been increased to $1,000,000 in 1911, and, like the parent company in Detroit, Henry Ford is the president and James Couzens the vice-president of the company.

Ten years ago the plant had 40,000 square feet of floor space, while today the total is 375,000 square feet.

The Ford officials of Canada are not very optimistic as to the business outlook in Canada. They say that under ordinary circumstances the outlook would have been splendid, but, under the present war conditions, which affect business in general to a great extent, one cannot make any predictions as to whether business will be good or bad next year. At the present time it is quiet.

1,600 Studebakers in 1914

Next to the Ford comes the Studebaker Corp. of Canada, Ltd., Walkerville, Ont., which was established in 1909 with a capital stock of $400,000 which has remained at that figure ever since. In 1914 about 1,600 Studebaker cars were made in Canada and for 1915 the schedule calls for at least 2,000.

The Studebaker officials are not only optimistic about the future of the Canadian automobile business, but, they believe that, as a matter of fact, 1915 will be the best year since the automobile was introduced in Canada.

Speaking on the subject one of the officials recently said: "Despite the disturbed condition of finances because of the European war, there is every indication that there will be more cars placed in Canada next season than ever before. Canada, being largely an agricultural nation, is already feeling the effects of the higher prices farm produce is demanding, and farmers are buying more freely than they have for several months."

The Hupp Motor Car Co. of Canada, Ltd., Windsor, Ont., started in business in 1911, the plant then having a total floorspace of 2,500 square feet. The output that first year was 175 cars made by a working force of fifty-six men.

In 1912 the shop men totaled 140 and 300 cars were made. In 1913 the production totaled 450 cars and 200 men were in the plant's employ. This year fifty men were added to the force and 550 cars were turned out. For 1915 the schedule calls for 600 cars and 250 men.

"In general, the business outlook is fair," said an official of the company. "It would have been a very good year without the war. People are very conservative and are spending money only for actual necessities and they keep the balance in the banks. While there will always be buyers of automobiles there is no doubt that the purchases by Canadians will not be heavy next year if the war lasts till spring. In some sections of the Dominion the outlook is better than in others, reports from Manitoba and Ontario, for instance, being fairly satisfactory thus far, while those from St. Johns are not as good."

Reo's Real Factory

The Reo Motor Car Co. of Canada, Ltd., located in St. Catharines, Ont., started in business in 1909 with a capital stock of $40,000 and a factory having an area of 26,000 square feet. Since then business has steadily increased and at present the plant occupies 71,000 square feet of space and the capital stock has been increased to $200,000.

This plant is as completely equipped as the Reo plant in Lansing to take care of the manufacturing, from the raw material to the finished product.

Speaking about the business in Canada at the present time and the outlook for the future, general manager E. E. Turnbull said: "At the present time conditions are undeniably unsettled owing to the war in which Great Britain is involved. This is chiefly noticeable in the falling off in fall business, of which there is usually a very good proportion, and we think that bettering of present conditions largely depends on the success of the allied forces in the present war. Should they be able to bring the war to a conclusion, say early next spring, undoubtedly confidence will be restored and business generally will quickly assume its former standard. On the other hand, if the war is prolonged late into the coming year we are inclined to think that it will have a somewhat depressing effect on business and realize, of course, that possibly this will be even more emphasized in our line of business."

Buicks Assembled at Oshawa, Ont.

A concern which is much more Canadian than American is the McLaughlin-Buick Co., also known as the McLaughlin Carriage Works, Oshawa, Ont. This company has been assembling the Buick cars in Canada for many years, and, while the frames and power plants come from the home plant in Flint, Mich., they build the bodies and otherwise complete the cars.

This year, it was stated by one of the Canadian dealers handling the car, 1,200 cars were made while from 1,600 to 2,000 are to be built in 1915.

One Truck Company

The Gramm Motor Truck Co. of Canada, Ltd., Walkerville, Ont., built about 100 trucks in 1914 and expects to have an equal production in 1915.

"Anyone telling you that the war is not affecting the whole automobile business in Canada, either does not know what he is talking about, or does not wish to tell of the real conditions," said one of the Gramm officials. "While Canada is only indirectly involved in the war, its effects are being felt in all lines of business. The people are spending money only when absolutely necessary and are investing less in automobiles, passenger or commercial cars, than at any time during the last 5 years. This refers however only to the last 3 months, since the war began."

Willys Not Started

The Willys-Overland Co., which purchased the former Schacht plant in Hamilton, Ont., last January, has not started to build there, but is using the factory as Canadian selling and distributing headquarters. The present European conflict has further delayed the company's original plans.

The Olds Motor Works operated a plant in Canada for some time but have discontinued it, finding it more practical to transact all their Canadian business from the plant in Lansing, Mich.

The Regal Motor Car Co. of Canada, Ltd., which started a plant in Berlin, Ont., about 6 months ago, is not yet operating it, that is, building cars there. Present conditions will still further delay its operation.

The plants of the R-C-H Corp. and of the Keeton Motors, Ltd., were discontinued last year.

The Maxwell Motor Co. of Canada, Ltd., was organized in 1913 in Windsor, Ont. No cars are either built or assembled but the finished product is received from the Detroit plant for distribution, the company being the general headquarters for Canada. However, with its increasing business it is not improbable that the time may come soon when a plant will be operated in the Dominion.

Whatever the conditions will be in Canada in 1915 these conditions will probably not have an important bearing upon the motor car manufacturers, as they will be able to dispose of their output to the British Colonies and to most all other foreign countries as it is a fact that quite a large percentage of the cars made in Canada are exported annually.

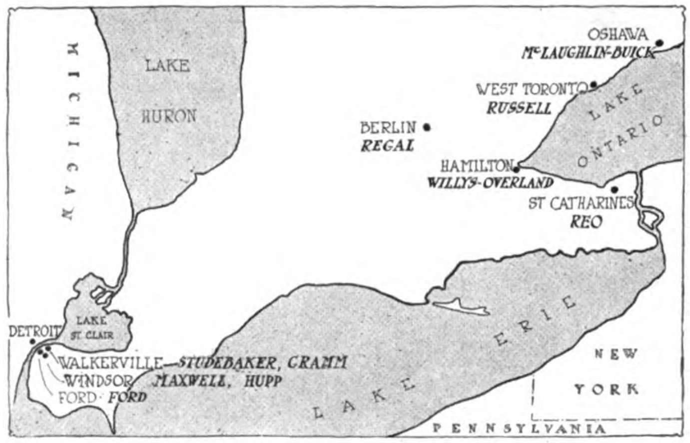
It was stated by a customs official that the Ford company exported fully one-third of its 1914 production, which would make a total of 6,000 cars. The Studebaker Corp., it was also stated, shipped a large percentage of its output to foreign lands.

As this happened under normal business conditions throughout the world, when all those countries where motor cars are made were at peace and exporting a large percentage of their output, it is quite reasonable to assume that now, when those countries are at war, when their export business is nil, it will mean a very large increase of the export business of the Canadian motor car makers.

Canadian Maker

The biggest Canadian automobile manufacturing company is the Russell Motor Car Co., Ltd., West Toronto, Ont. Its plant is located on a 27-acre site, covers 10 acres of ground and has about 8 acres of manufacturing floorspace. It is stated that over 1,500 men are employed on an average throughout the year and that the 1915 output will be about 1,500 cars. This company makes the Knight type motor.

The company has its inception in the consolidation of the various interests of the H. A. Lozier Co., the Gould Bicycle Co., the Massey-Harris Co., and the Welland Vale Mfg. Co.



Map of part of Canada, showing the locations of Canadian-American automobile manufacturing concerns, that is to say, Canadian firms building or assembling cars of American origin. There are six of these firms in operation, five of them producing passenger cars, while the other builds trucks. Two of the companies included in the map have not yet started active operations in the plants indicated. One other is a distributing station, while the remaining one is a purely Canadian firm

all being consolidated in one factory at West Toronto, operating under the name of the Canada Cycle & Motor Co., Ltd.

Several cars were developed but until 1904 little was accomplished. At that time the plant consisted of about five buildings whereas at the present time it comprises nineteen.

The company has seven branches in the principal cities of Canada as well as many service depots. A large business is done with Australia and New Zealand, directed from a branch depot in Melbourne.

The present capital stock of the company is $2,000,000.

One of the principal reasons why American automobile manufacturers have established factories or are assembling cars in Canada is due to the liberal inducements offered by the municipalities. In Windsor, for instance, the city grants tax exemptions, free light and free water for 10 years to any new industrial concern employing 25 or more men. This rule is however not strictly adhered to and several companies have started in business with less than 25 men and have been given all the exemptions and other privileges.

The city-owned land is sold to the firms at the original cost. There are two factory districts. In district No. 2, the price paid by the city for its land was $850 an acre. It has been appraised at from $2,000 to $2,500 recently, yet the land is sold at no increase.

All concerns establishing a factory in Canada must get a Dominion charter, which costs about $50.

Chicago Garage Storage Charges Unprofitable

CHICAGO, ILL., Nov. 21—The Chicago Automobile Trade Assn. finds that it is unprofitable for dealers along the row to store cars or bodies for a rate less than $7 per month for the complete cars or $5 per month for bodies, either closed or open. The committee that has been investigating has found that the expense of replacing stolen equipment, such as electric horns, speedometers, tail lamps and similar parts is unusually severe. The retrimming of limousine bodies when they have become moth-eaten even under the most minute care, is another item that is very burdensome.

The labor and bother in checking off the stripping from a car, such as carpets, rugs, toilet cases, watches, tires, gloves, chauffeur caps, maps, etc., also must be taken into consideration. The expenses of porters in washing cars and bodies left in storage and constant brushing and cleaning and cost of naphthaline or other moth-preventives among carpets, also is another item that the committee has found to be very expensive.

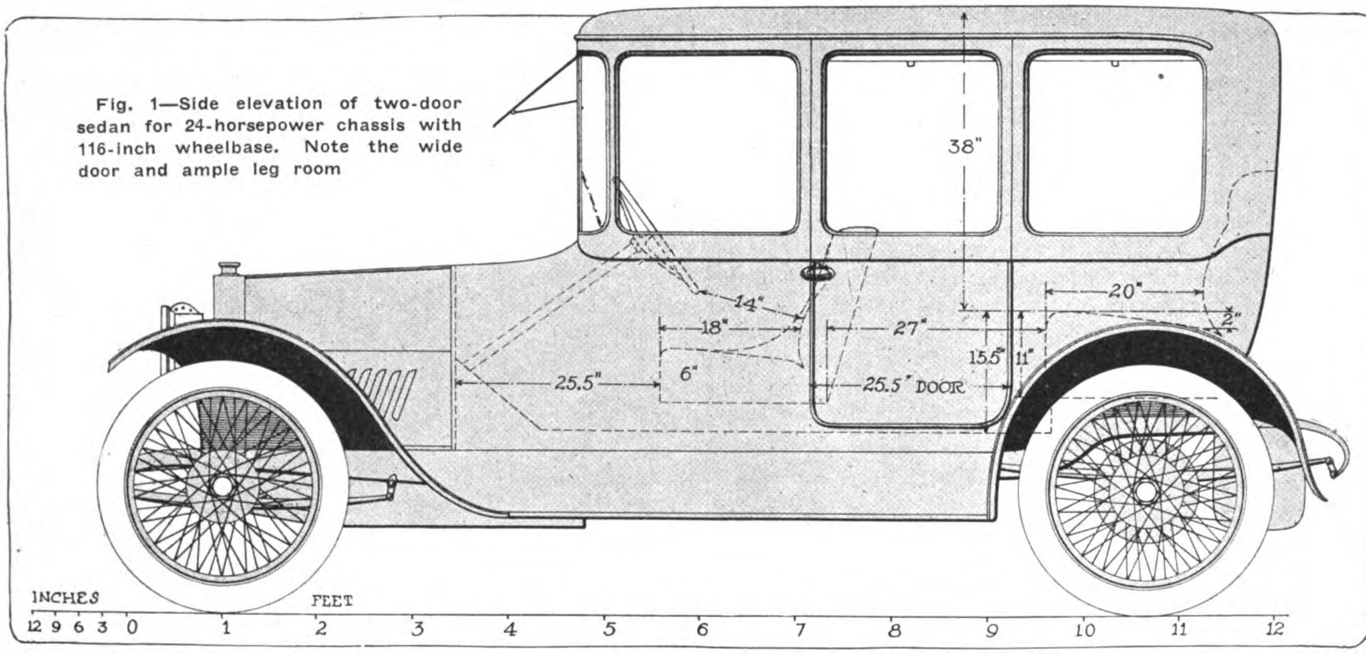


Fig. 1—Side elevation of two-door sedan for 24-horsepower chassis with 116-inch wheelbase. Note the wide door and ample leg room

Two-Door Sedan with Separate Front Seats

A Design which Gives the Car a Low, Compact Appearance—Metal Panels on Wood Frame — Construction Features

By George J. Mercer

ONE of the most pleasing inclosed single-compartment body designs that has been brought out this season is illustrated and described herewith. As illustrated, it is mounted on a 24-horsepower chassis with a wheelbase of 116 inches and having wire wheels, 32-inch tires, three-quarter elliptic rear springs and a sloping type of hood.

The sedan body having a single door in the middle on each side is well adapted for a short chassis, as the door can be wide without cutting the lower corner. As shown in Fig. 1 it is 25.5 inches and this allows all the windows on the side to be spaced equally. The door opens direct to the rear seat and the 7-inch passage between the front seats, Fig. 3, allows the two occupants to get in and out.

Front Seats Are Individual

These seats are individual and are fastened permanently to the floor, the backs are concaved to make them comfortable and the front of the cushions are rounded off to allow passing the change lever. It is possible to put the gasoline tank under these seats or under the cowl or at the rear, as illustrated.

The steering wheel column has the runabout rake and this enables the cowl to be long and the distance from the front of the seat to the dash for leg room is also generous. In Fig. 3 the width of the front and rear seats is shown and in Fig. 1 are the height from the floor to seat and from that to under the roof. These dimensions are standard and the slope of the rear cushion of 2 inches from front to back is less than former practice. Today, however, the public is not calling for the sloping cushion. The rear cushion is 11 inches thick and the front ones are 6 inches.

The low, compact look of this body is partly due to the rounded roof and round front corners. Fig. 3 best illustrates the rounded front as well as the near-flat look of the sides. The taper of the body from back to front is very slight, as the width across the outside of the body is only slightly greater at the rear seat than at the front.

In Figs. 1 and 2 the round front corners are shown formed by curved glass. These corner glasses are permanent and the framing to which they are fastened on their front edge is of metal and narrow, while the front windshield is 34 inches wide. This, with the rounded corners, gives the driver a more unobstructed vision than any other style of body. In addition, the round corners and roof give the body non-wind-resisting features. The front glass is divided, the upper swinging outward to form the storm visor and the lower part swinging inward to provide ventilation. All the side glasses are made to drop and, with the exception of the one on each side at the rear of the door, drop their full length. In Fig. 4 the rear glass is shown. This is large and stationary. The rounded corners of the window openings conform in design to the rest of the body.

Metal Panels on Wood Frame

The construction of the body is with all-metal panels over the customary wood framing, the entire outer surface being metal covered including the roof. The sheets forming the cowl and the body's lower sides, including the doors and the lower back, are of 16-gauge aluminum. The skeleton upper part of the doors, the windows forward of the doors and the front are aluminum castings, but the upper back, side panels and roof can be either all steel or steel and aluminum.

Joints will have to be made where the roof and back panels meet, and, as there are no mouldings to cover the joints except the side drip moulding, which terminates at the rear window, the joint across the roof must be flush finished. This

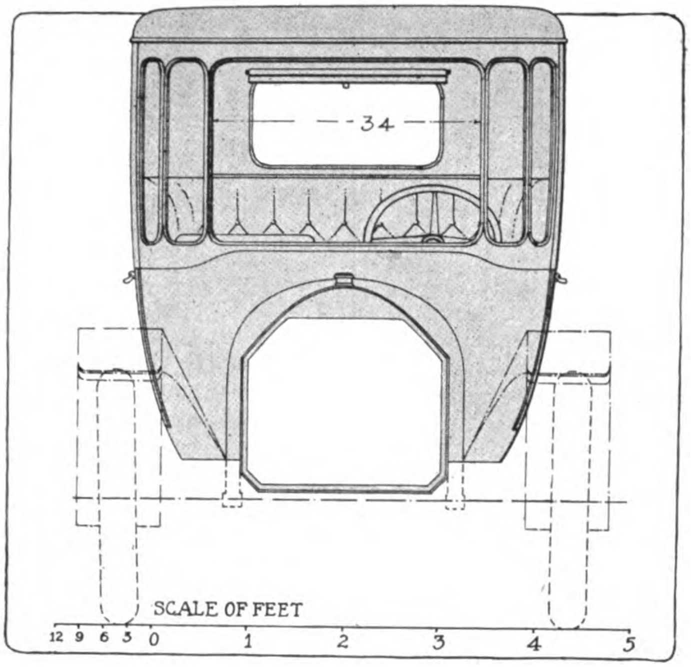

Fig. 2—Front view of sedan, showing how the cowl blends into the body lines

can be done, whether the metal used is steel or steel and aluminum, by fastening the edges of the metal with wood screws to the wood framing, first putting under the joint a steel strip wide enough to lap under both sheets. Then, after the outer sheets are secured with screws, the joint is filled with solder, the steel strip underneath helping to hold this permanently.

Method of Applying Panels

All the panels are assembled on the body without mouldings to cover the joints, the upper side panels being put on over the top edge of the lower panels. The metal of the upper panels is turned under and hooked over a steel band bolted through the wood framing. This is a standard form of construction and while it costs a little more, it gives the body a clean finish that is well worth the difference.

When the roof is made of metal, as here specified, it requires that the under side must be well backed up with deadening in the shape of wood and felt to prevent the bell sound or synchronizing of the metal ring.

The roof and window lines are straight until they flow into the rounded corners. This is accentuated by the flat sides caused by the width of the body being nearly the same across at the back and front and by the cowl, which blends easily with the body lines and gives a long appearance to the hood.

It is not considered so objectionable today as formerly to make chassis changes, such as changing the hood or the rake of the steering column or the mudguards, in order to accommodate a special design of body. In fact no opposition is offered by the dealer if the change in the chassis will make the assembled car a harmonious whole. Fortunately no changes from the standard chassis, provided it has the runabout rake to the steering column and runabout guards, will be required in order to fit the design here illustrated. The dash is made integral with the body which will require a little re-assembling and the gasoline tank will perhaps have to be re-located. The rear guards also will have to be either fitted to the body or re-made, but this is generally necessary in all new closed bodies. This design calls for a small wheel house as indicated in Fig. 4 by dotted lines. This is simply a flattening of the round or bulge of the panel and will not call for extra framing inside.

Two Combination Lamps

Two light combination lamps are used at the front, no pillar or dash lamps being included, while inside there are two dome lights centrally located and possibly a small finder light under the cowl to read the instrument board. A few cars have had a glass panel let in at the top of the cowl to light inside, but this has not found much favor as it is not often seen. This body is for winter use and therefore the trimming should be luxuriously thick. On the rear seat, arm rests are used on the sides and the seat is wide enough to have a division in the center. This can be made removable when a child or small person is crowded in as a third occupant. Arm holders should be used if a middle division is not installed, and these are made on a rod to slide to the desired position.

Choice of trimming material should lie between the imported silver-gray Bedfords and the slightly darker mixed goods, if the car is to see rough usage. The darker material will last longer without showing soil marks. The entire inside of the body should be trimmed, and the only wood finish be the garnish around the windows. This can be any of the woods commonly used and it should be richly stained to bring out the grain and to protect it from being injured by moisture.

The Finishing Touches

The frameless glass is raised by lift straps of broad lace and these are now put in so that the end is dropped into a slot back of the trimming, the top entrance to which is through the garnish rail. This does not mar the trimming line, except at the door, where it is necessary to have fasteners to hold the glass in different positions. These fasteners are nickel or silver finished to match the dome light metal and the toilet articles as well as the rod on which the arm holder slides. Less lace is used now than formerly and in some cases the broadlace is eliminated except for the window lifts.

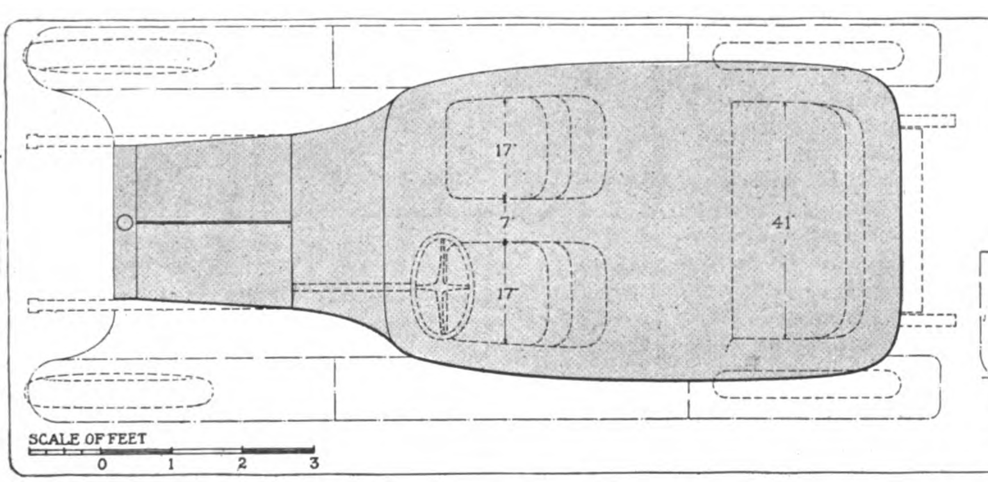

Fig. 3—Plan view of sedan, showing cowl and body lines and seating arrangement.

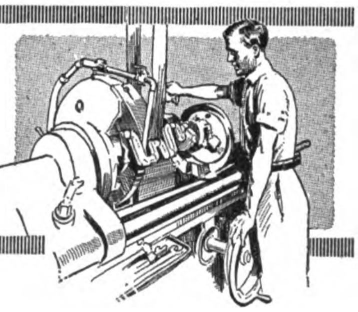
The Rostrum



This department is for the instruction of the readers and all are at liberty to ask questions. Be sure to give full name and address that we may send you a reply by letter if there is no space in the Rostrum. If you wish to sign a fictitious name, sign it, also sign your own.

Wind Resistance to Reduce Back Pressure

EDITOR THE AUTOMOBILE:—An interesting method, which I noticed recently, of reducing back pressure on a racing machine is that adopted by the Chevrolet company on its two racers. As shown in Fig. 1, the device consists of a straight exhaust pipe about 4 inches in diameter, at the end of which there is a large funnel-shaped piece which catches the onrushing air due to the speed of the car and forces it through the opening. This undoubtedly has a strong ejector action and sucks the exhaust out with it. Since the area of the mouth of the funnel is several times that of the exhaust pipe, the speed of the air through the funnel must be 200 or 300 miles per hour when the car is running at 60 or 80.

Detroit, Mich. O. R. H.

Where to Buy Paper Covers

Editor THE AUTOMOBILE:—Please give me the name and address of the firm that manufactures paper automobile covers. These paper bags, as some call them, will entirely cover a car and are intended for storing a car during the winter.

Belding, Mich. JOHN W. ZINDLER.

—According to the Automobile Trade Directory there are two concerns making these bags: the Safepack Paper Mills, 411 Court street, Brockton, Mass., and the Seinsheimer Paper Co., York street and McLean avenue, Cincinnati, O.

Compressor Objectionable for Racer

Editor THE AUTOMOBILE:—What is the objection to compressing the intake gas on a racing-car motor to develop more power?

By intake gas I mean the mixture of gas and air, after passing through the carbureter and before entering the cylinders.

For example: Suppose the intake gas is held at a uniform pressure of 2 pounds. Increase the cylinder clearance so as not to bring the compression over 80 or 85 pounds. Strengthen the pistons, connecting rods, cylinders, etc., if necessary.

Why would not the power of the motor be greatly increased especially on small motors? If a failure, why?

San Gabriel, Cal. E. H. BUCHNELL.

—It is not likely that increased power would be obtained. Let us understand the conditions first of all. Consider a high-speed racing motor 4 by 7 inches. Its compression would possibly be 120 pounds gauge and its clearance approximately 18 per cent. of the displacement of a single piston. Suppose we double the clearance so that twice the charge may be taken in. In order to maintain the compression at 120 pounds, it is necessary to supply the intake air at a pressure of 25 pounds per square inch.

Although twice the charge is taken in, the explosion pressure will be no greater, because the clearance space is double. However, the expansion curve will not drop in pressure so quickly as the piston moves out because there is more gas to be expanded in the same piston displacement. Therefore, the pressure during the working stroke will be generally higher, or in other words the mean or average pressure will be increased. But with this increased power has come a greater consumption of power by the motor, so that it is doubtful whether there is any net power gain. It takes power to overcome the friction losses in the compressor, and it takes power to compress the extra amount of gas. Furthermore, the compressor mechanism, since it must handle large volumes of gas, is bulky and adds considerable weight, which still further cuts down the effective power output. Possibly the space the compressor requires necessitates the lengthening of the chassis, which adds still more weight. Therefore it is seen that little would be gained by adopting your suggestion.

An increase of 2 pounds in the pressure would make little difference.

Wants Radiator Design Data

Editor THE AUTOMOBILE:—If you have any information on radiators for internal combustion engines, giving rules for the radiating surface, generally allotted per horsepower, and the proper relative proportions between cross-section area of air passages and their length, etc., I would highly appreciate it.

Waynesboro, Pa. G. ANDERSON.

—We have no data on this subject. The amount of radiating surface depends on the speed of flow of the water, the rate at which the air is sucked through and the construction of the water passages. It is impossible to give exact rules except for a given radiator design. We would suggest that you select the type of radiator you wish to use and ask the manufacturer's advice as to the size of radiator, size and speed of pump and fan, giving him the details as to the motor.

Should Fit New Springs

Editor THE AUTOMOBILE:—My car is a 1911 model with three-quarter elliptic springs in the rear, the small bottom leaves of which have given trouble from within a few months of purchase, new, by first flattening and then cracking in a clean, straight line, not at the bolt hole, but at the front end of the spring bed-plate which is welded to the axle. I prolonged the breaking periods by inserting extra leaves, but

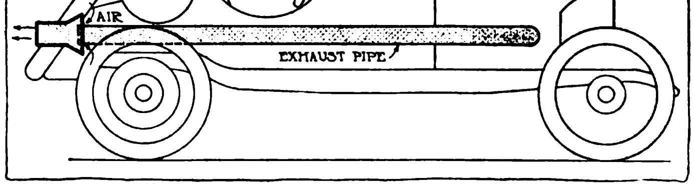


Fig. 1—Chevrolet racer, showing method of reducing back pressure

they finally gave way also; therefore I am wondering whether these breaks are caused by the fact that the car is not equipped with radius rods, that is, a short rod on each side of the car, having a knuckle joint where it is connected to the frame and a simple joint where it is attached to the rear axle by a collar, the same as I have seen on some models of the Buick?

Honesdale, Pa. BENJAMIN H. DITTRICH.

—Radius rods will not help you out of your difficulty. The best remedy is to obtain a new set of springs from the factory. Radius rods take the driving strain, that is, the forward thrust, but not the twisting strain. Possibly you meant a torsion rod instead of radius rods, as the torsion rod is for the purpose of taking torque reaction due to the rotation of the wheels. However, it would be very difficult to attach such a rod, and it is doubtful whether it would prevent the breaking of the springs.

In the beginning your spring trouble may have been due to overloading the car or to a defective set of springs. Since then you have repaired these springs from time to time as the leaves broke. Probably the repairs were made with spring leaves at hand instead of new ones from the factory.

These springs have now seen at least 4 years of service and are probably worn out, and therefore it would be best for all around satisfaction to obtain a new set.

How to Install Ammeter

Editor THE AUTOMOBILE:—Please explain fully by diagram how to wire up an ammeter on the Delco System used on 25-B Buick 1914 model?

Cuba, Kan. L. M. BRIGHAM.

—First cut the strap A connecting the two terminals, as shown at the left in Fig. 2. On some machines this strap is on the inside of the frame as shown at B, in which case it is necessary to remove the motor-generator from the car and disassemble it.

When this is done, a tap is made on the wire from the upper terminal and a wire run from the negative side of the ammeter to the lower terminal.

The meter should be of the center-zero type, reading at least 10 amperes discharge and 20 to 30 amperes charge. The meter will then indicate the current charging the battery and what is discharged from it with the exception of the cranking current. For example, if the lights and ignition are using 6 amperes and the generator is delivering 12 amperes the meter will indicate 6 amperes charge.

Caring for Batteries in Winter

Editor THE AUTOMOBILE:—Will you kindly advise me the best way to care for the storage batteries during the winter?

Goshen, Ind. WILBUR RIDEMOUR.

—Keep them fully charged, filled with water and of proper gravity.

The electrolyte of a cell that has been fully charged should be about 1.300. While the gravity of the battery will change with age to a certain extent, it will give good service between the densities of 1.250 and 1.300. When, after testing with a hydrometer, it is found that the gravity is above 1.300 with the battery fully charged, pure water should be added to reduce it to the proper amount. If the addition of the water raises the level more than a .5-inch above the tops of the plates some of the electrolyte must be removed. Low gravity in a cell is caused by lack of charge, the acid being combined in the plates as sulphate; through acid being spilled; through a cracked jar, and through the accumulation of sediment in the bottom of the jars.

Do not add acid until sure that the battery is fully charged and that there is no appreciable amount of sulphate in the plates. For example, if the electrolyte in the cell should be adjusted to 1.275 when 50 points of acid remained in the plates, the gravity would come up to 1.325, if the cell were afterward charged to its maximum. Therefore it is important to first raise the gravity as high as possible by charging during a period of at least 24 hours at one-half the finishing rate. Then remove the electrolyte down to the tops of the plates and replace with 1.300 electrolyte.

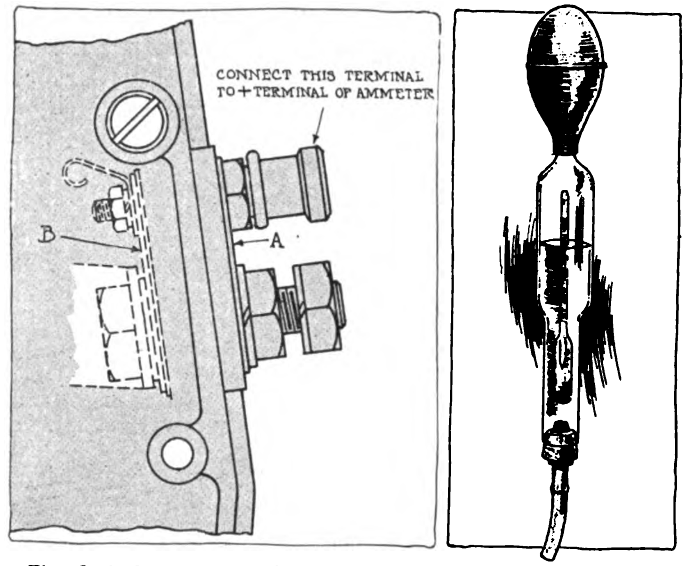

Fig. 2—Left—Diagram showing attachment of ammeter to 1914 Buick Delco system. Fig.—3—Right—Syringe hydrometer for testing the gravity of the electrolyte in storage batteries

The density of the electrolyte is told by means of a hydrometer, which is a glass float, weighted at the bottom to hold it vertical and with a graduated scale on the upper end to indicate the gravity. The heavier the liquid, the further out from the surface it extends. Therefore the scale reading at the surface gives the specific gravity of the liquid. Evidently with this type of instrument some of the electrolyte must be removed from the cell and placed in a convenient vessel. To obviate this difficulty the hydrometer syringe shown in Fig. 3 was devised. The liquid is drawn into the syringe, in which is contained a hydrometer and in which the hydrometer is floated. It is seen that the syringe makes a more convenient containing vessel for the liquid. There is no danger of spilling the acid during the operation, and it is much quicker and simpler than the other method. Care must be taken in using the syringe not to allow the hydrometer to touch the sides of the syringe, as the friction might alter the reading. For this reason the syringe should be held vertical when it is read.

It is well to note that the gravity of the cells under normal conditions is an indication of the state of charge, and when the gravity has dropped 100 or 150 points it is evident that recharging is required.

Two Ways to Store

There are two methods of storing batteries. One for periods of less than a year and the other for more than this time. The former is known as wet storage and the latter as dry storage. Dry storage is also used where a battery is to lie idle for less than a year but is in such a condition as to require dismantling for cleaning or repairs at the end of this period.

The wet storage method is very little trouble. The battery is given an equalizing charge and water is added every 2 to 4 weeks, depending on the temperature, and therefore on the rate of evaporation. At least once in 4 months the battery should be charged at one-half its normal finishing rate until all the cells have gassed continuously for a period of 3 hours.

Dry storage requires that the battery be completely taken apart, after it has been given an equalizing charge, cleaned and all worn out parts replaced. It is best to make a sketch

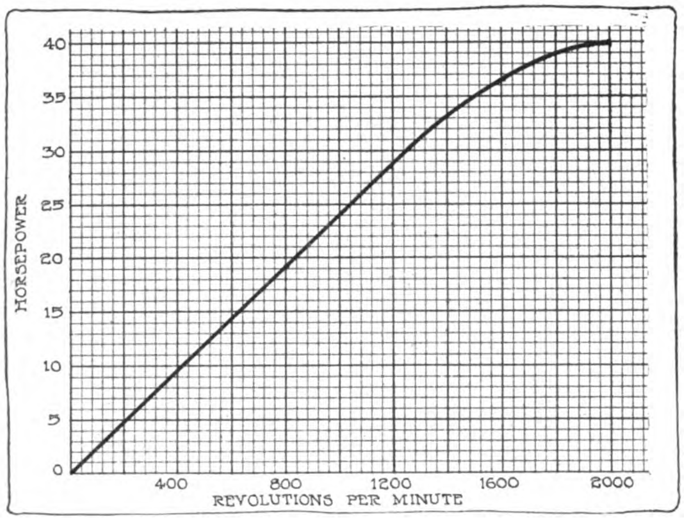

Fig. 4—Horsepower curve of Jeffery four motor measuring 3.75 by 5.25 inches

of the parts, so that no difficulty will be experienced in assembling it again.

The rubber separators should be washed and stored away. The positive plates are put into empty jars and the negative groups are placed in the remaining jars and the electrolyte which was saved for this purpose is poured over them and left there for 5 hours. It is then poured off, and the plates are stored in the empty jars.

Questions Concerning Jeffery Four

Editor THE AUTOMOBILE:—Will you please give me the following information regarding the 1914 Jeffery four:

1—Horsepower curve.

2—Gear ratio.

3—Explanation of steering gear and its adjustment.

4—What is the easiest way to change the lubricant?

5—Sketch the oil system.

6—Illustrate the gasoline pressure pump.

7—What is the metric size of tires that replace 34 by 4 tires?

8—Does a spark plug gather more carbon than usual if the porcelain is broken; if so, why?

9—How can I clean the radiator with soda?

10—Why does a Vesta 1913 type generator, model D2, properly set, only furnish 3 amperes of charge, running the car at a speed of 20 miles? The car is a 1913 Buick, model 30. The gear ratio is 1 to 1½, silent-chain drive, and wiring is all right. Can you advise me of some method to better the current output?

South Bethlehem, Pa. L. F. ORLANDINI.

—1—The horsepower curve of this motor is shown in Fig. 4.

2—The gear ratio is 13 to 51 on direct.

3—The steering gear is of the worm and gear type. The gear is mounted on the squared shaft of the bell crank.

If worn, the gear should be removed and revolved one-quarter turn, bringing into action a new section.

The bell crank connects with the knuckle steering arm by means of a fore and aft rod. The rear end of this rod is adjustable. To adjust, back off the lock nut, loosen the bolt in the hood and turn the ball and socket until the proper adjustment is obtained. Do not tighten it so that it will bind.

4—There is an oil drain in the form of a petcock on the left side of the motor at the bottom of the crankcase. Turn this on and allow all the oil to flow out. Then put a quart of kerosene in the oil filler opening and turn the motor over a few times to distribute the liquid. This will cut any gummed oil and will carry the sediment to the bottom of the crankcase, where it will flow out of the drain. Finally fill the system with a good quality of medium-grade oil.

The oil should be drained out every 2,000 miles, according to the Jeffery company. The oil reservoir should be filled every 200 miles. On the right side of the motor there is a gauge with high and low points marked on it.

5—The oiling system is illustrated by diagram in Fig. 5. It is a combination splash and pressure system. The bottom of the crankcase forms an oil reservoir or sump. Oil is drawn from the sump through a rectangular-shaped screen by a plunger pump worked by an eccentric on the camshaft. The oil is forced to a pipe extending the length of the crankcase in the upper right side. From this pipe oil is fed to the main bearings, camshaft bearings, timing gears and connecting rods. A metal trough retains a supply of oil for each connecting-rod. The splash of the rod dipping into the trough lubricates the pistons, wrist-pins and cylinders.

Surplus oil drains back to the sump, whence it is drawn again for circulation through the motor. A gauge on the dash indicates the oil pressure. If the hand is stationary and at zero, the pump is not working, and investigation should be made.

6—The gasoline pressure pump is illustrated in Fig. 6.

7—The corresponding metric size is 875 by 105 millimeters. This shoe will fit a little loose on a 34 by 4-inch rim. Therefore, if it is applied to a clincher rim do not fail to use lugs. If a quick detachable rim is used, care must be taken while the tire is inflated, because there is danger of the bead coming off, although after the tire is fully inflated it will stay put.

8—If there is a generous supply of oil it is possible that the plug will soot quickly, due to the fact that the crack allows the current to short circuit part of the time and the cylinder misses. Therefore the oil which accumulates on it during the three strokes preceding the power stroke is not burned off. When several explosions are missed in succession the amount of oil settling on the plug is considerable, and when an explosion does occur the intense heat burns and vaporizes some of the oil but leaves part of it in the form of a carbon deposit on the plug.

9—Use a boiling-hot solution containing 1 pound of soda to 2 gallons of water. Pour this through the system until all grease is removed. It must be understood that the soda only cuts the grease and oil, but in so doing it releases a large amount of dirt held by these lubricating materials. If the system is free from grease and oil possibly it will be sufficient to flush the system to remove the sand and grit. If very hard water has been used it may be that the water passages are covered with a deposit, in which case it will be necessary to apply a boiler compound.

10—The driving belt requires tightening. Loosen the three

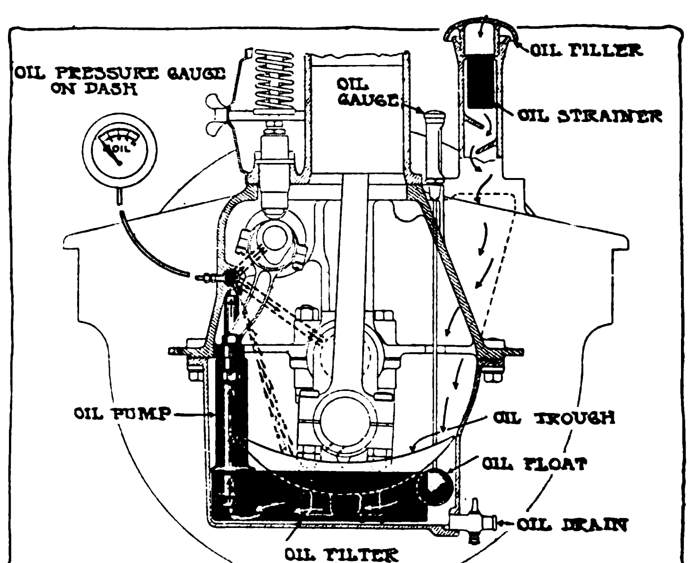

Fig. 5—Oiling system on Jeffery four motor

bolts holding the generator to its base and move it a little farther away to take up the slack.

How to Straighten Front Axle

Editor THE AUTOMOBILE:—1—I have a front axle of a standard design on a 1910 car. It is bent about 1 1-2 inches from the spring seat to the outer end of the axle, a distance of about 10 inches. I wrote to the makers and they said that it would have to be straightened and heat treated again to make it safe, but that the holes for the bushings were liable to be enlarged by the heat treatment and the axle thus spoiled.

2—What is the customary manner of straightening these, and are they considered safe afterwards?

3—What effect would it have on the steel to straighten it cold, and what, hot?

Harrisville, N. Y. HUDSON DE GRAFF.

—1—This axle should be heated to a cherry red heat and then straightened. The heat should be applied at the bend only, and as this is 10 inches from the king pin bushings there is no reason why the latter should be heated, and therefore no danger of them becoming enlarged. In fact it is doubtful whether they would be enlarged even if exposed directly to the heat. It is not necessary to give the axle any heat treatment after it is straightened.

2—This is the common method. The axle should be safe after being repaired in the manner outlined.

3—If it were straightened cold it might fracture.

Wants to Buy Racing Motor

Editor THE AUTOMOBILE:—I want a motor for a racing car, one that I can get high speed from, and come under the 300-displacement. What motor would you advise me to buy?

Los Angeles, Cal. W. F. GRIFFITH.

—There is no concern building motors of this type as stock. Probably any of the concerns making motors will be glad to build a motor to your specifications. Write the Wisconsin Motor Mfg. Co., Milwaukee, Wis., and F. S. Duesenberg, Des Moines, Ia.

Ford Planetary Gearset Not Invented

Editor THE AUTOMOBILE:—1—Who invented the planetary transmission used on Ford cars?

2—Who made the first four-cycle motor used on Ford cars?

3—How are the platinum points fastened to screws of a magneto?

4—What advantages are gained in disconnecting the countershaft gears when on direct drive?

5—What advantages are gained by fitting three piston rings to the groove instead of one?

6—Who makes the motor used on the Dodge car?

New York City, N. Y. W. R. C.

—1—This gearset was not invented but designed. It was produced in the Ford factory and differs only in detail from other planetary gearsets, which have been used on various cars from time to time. It is not an invention, since there were similar ones made before it.

2—This also was made by the Ford company. This concern has always used a four-cycle motor.

3—One method is to hard solder the points in place. The first step is to cut two small slots at right angles in the end of the two members carrying the points. Then by the aid of the brass solder the points are fastened in place.

4—Disconnecting the countershaft gears when on direct drive increases the silence of operation and reduces the wear and power consumed by the friction of rotation. Obviously the countershaft must make a small amount of noise even when it is rotated without doing any driving. Also this rotation causes a small amount of wear, and a slight quantity of power is used up which might otherwise be employed in propelling the car.

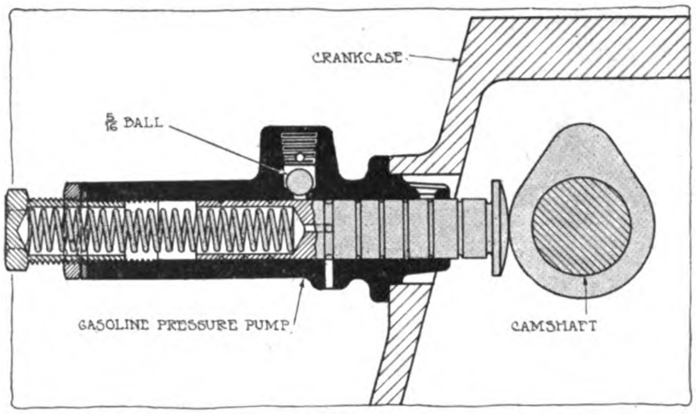

Fig. 6—Fuel pump construction found on Jeffery four

5—The advantages claimed for special piston rings such as this one are that it holds compression better, prevents oil from entering the compression chamber more effectively, and in some cases reduces the wear on the cylinder walls.

6—This motor is made by the Dodge company.

Kardo Patents Explained

Editor THE AUTOMOBILE:—Will you kindly inform me of what the Kardo patents consist?

Philadelphia, Pa. B. A. MEYER.

—The Kardo patents are eight in number and govern claims dealing with the gearset, driving mechanism and rear axle construction of the automobile. To quote from THE AUTOMOBILE for March 12, 1914:

The Kardo Co., recently incorporated in Ohio with headquarters at Cleveland and having a capitalization of $1,000,000, looms up as one of the most important of patent holding companies in the automobile industry, and has as its officers and directors very prominent figures in the motor car field. Alvan Macauley, vice-president and general manager of the Packard Motor Car Co., heads the new Cleveland organization, and T. W. Frech, of the Peerless, is vice-president, and F. C. Dorn, American Ball Bearing Co., is secretary and treasurer. Besides these men, the board of directors of the Kardo Co. includes Milton Tibbetts, patent counsel of the Packard company; F. S. Terry, of the Peerless company, and Walter C. Baker, of the American Ball Bearing Co.

Although the Kardo Co. is incorporated for the purpose of "acquiring, owning and dealing in vehicle patents," its chief concern at this time is with the axle patents of the Packard Motor Car Co., the Peerless Motor Car Co., and the American Ball Bearing Co. These patents have so overlapped and dovetailed one another that some sort of holding company for all of them was necessary to prevent litigation among the three concerns above named. By the transfer of all patents to the Kardo Co. protection is thus gained for all, since all can use the patents of all without conflict.

The formation of this holding concern for these axle patents makes a very strong combination, and since all other axles are said to be infringements of one or more of these patents, it is pointed out that other makers will either have to take out licenses or lay themselves open to litigation.

In a statement issued recently the Kardo Co. says of these patents:

"The patents are now owned by the Kardo Co. Some licenses under them have been granted and the company is negotiating others at the present time. Of course, the usual royalty reservations will be made, and manufacturers will receive licenses that will insure them the right to make and sell to their customers axles that are free from charges of infringement."

The Kardo Co. holds eight patents, as follows: 608,017, dated July 26, 1898, to W. C. Baker, on an anti-friction bearing for use in a front axle; 664,478, December 25, 1900, Hopewell patents, rear axle on removable pinion mounting; 705,304, July 22, 1902, Sangster patent of Packard company, which covers broadly adjustment of bevel gears; 783,168, February 21, 1905, Baker rear axle patent; 792,690, June 20, 1905, on bevel gear drive and compensating mechanism; 950,191, February 22, 1910, on adjustment bevel gearing—this is an improvement on the Sangster patent; 1,013,450, January 2, 1912, on rear axle transmission, and also the re-issue 12,966, June 1, 1909, on power transmission mechanism for automobiles which covers Peerless rear axle with universal joints and removable features.

The patents are described in detail in the issues for March 17 and 24.

In the October 22 issue on page 763 it was stated that the Berliet, a French machine, was no longer imported. Since then Lucien Babel, 371 East Twenty-ninth street, Chicago, Ill., has written us stating that he is representing this machine.

The Engineering Digest

An Untechnical Study of the Balancing of Motors—Leading to Fullagar System of Cross-connected Pistons

THOUGH the need of avoiding violent vibrations has compelled motor builders, since the very beginning of the motor boat and automobile industries, to pay considerable attention to the principles involved in the balancing of motors, it is only in recent years that practical construction has followed theory into the last refinements in this matter, the demand for complete silence of motors and the ever increasing motor speed leaving no choice of doing otherwise, while in the case of aviation motors, which are necessarily suspended in a very slender frame, the absence of even the minor vibrations is a condition for keeping intact the tension of the guy wires and the nicely adjusted strength of the whole aeroplane structure.

Probably on no other subject relating to motor engineering does the conception of the practical requirements get snarled up so stubbornly in the multitude of words needed for their adequate and exhaustive explanation. Provisions made for reducing vibrations of one sort are likely to introduce other ones of a different nature and origin, as when the number of cylinders is increased and the crankshaft at the same time is lengthened or when parts are lightened to reduce unbalanced momentums and the loss of rigidity caused by the change is not fully obviated.

The difficulties in presenting the subject so that all can understand it are met by H. F. Fullagar of Newcastle, England, in a paper to be read before the Institution of Mechanical Engineers, by showing simple outlines of constructions in each of which one or another or several of the five different causes of vibrations are eliminated, while—to save a maze of reasoning—leaving it to the reader to grasp from direct contemplation of the construction involved in each case how the end is attained. A rapid survey of the requirements is thereby reached, and this may be found of value, though it will be noticed that the means for neutralizing or avoiding vibration in the four-cylinder motor of standard automobile pattern are touched upon only very lightly, the author's preference running to more radical designs, apparently with aviation purposes mainly in view. His presentation, which invites discussion in many places, is substantially as follows, with reproduction of his illustrations:

Absolute freedom from vibration involves balance of two kinds, balance of mass and balance of impulse.

Balance of Mass Only

Balance of mass exists if the inertia forces due to the acceleration of rotating and reciprocating parts neutralize each other and have no external resultant when the engine is driven from an external source.

The balancing of the rotating members presents no theoretical difficulty, provided the crankcase is sufficiently rigid to resist the torque reactions set up.

[The exception may here be taken that the masses should be balanced not only equally on both sides of the axis of rotation, as is usually done, but also as nearly as possible in the same transverse planes, as now done in a number of high-speed motors.]

The inertia of reciprocating parts is compounded of forces which the understanding classifies as primary and secondary, the primary ones being due to the reciprocation in itself and the secondary forces to those irregularities in the speed of the reciprocation which are caused by using a connecting-rod of limited length. Reciprocation as such implies a harmonically repeated reversal of inertia, and the secondary irregularities are also almost simply harmonic in character but of double the frequency. ["Double frequency" is a term not generally used in this connection in treatises on the balancing of motors, but to discuss it would mean a long digression. The inserted sketch Fig. O, indicates the nature of the secondary irregularities. When the connecting-rod A is at B or C, at the largest possible angle with the axis of the cylinder, there is for this reason a relative retardation of the piston speed and this retardation does not occur quite at the moments, indicated by D and E, when the piston speed is maximum by reason of the direction of the crankpin movement. As BFC is shorter than CGB the retardations occur at two unequal intervals, so that the periodicity is not quite simple-harmonic. The portion to the right in the diagram indicates the modification of the irregularities occurring when the cylinders are offset with relation to the crankshaft. The horizontal component of the oblique thrusts between crankpin and cylinder walls, by way of the connecting-rod and piston, should also be mentioned among the secondary unbalanced mass effects which cause vibration, though stronger components of this kind occur as impulses.—Ed.]

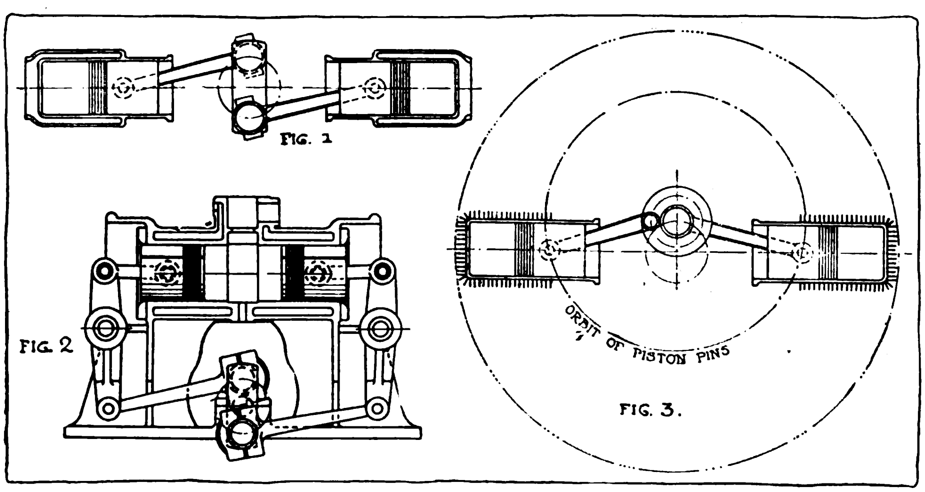

Fig. 1—Mass perfectly balanced. Fig. 2—Mass and impulse balanced; torque unbalanced. Fig. 3—Rotative motor; mass balanced

Perfect balance of both primary and secondary forces can together be secured only by placing connecting-rods on opposite sides of the crankshaft, Figs. 1 and 2. If as usual the crankshaft revolves, the connecting-rods must be attached to opposite cranks, but if the cylinders revolve, both connecting-rods can be attached to a single crank, Fig. 3. These constructions have however only limited application.

The four-cylinder four-cycle automobile engine necessarily has its cranks in one plane and 180 degrees apart, to give uniformity of impulse, but in this case the secondary forces are wholly unbalanced. When the plane of the cranks is horizontal the connecting-rod has moved the piston to below midstroke by the amount *a*, Fig. 4, and this amounts to one-sixteenth of the stroke if the length of the connecting-rod is four times the crank radius. As this displacement occurs twice per revolution and affects all four pistons, the secondary forces set free are equivalent to the inertia of a single piston moving the whole stroke but acting with double the frequency. When two such sets of four cylinders are placed

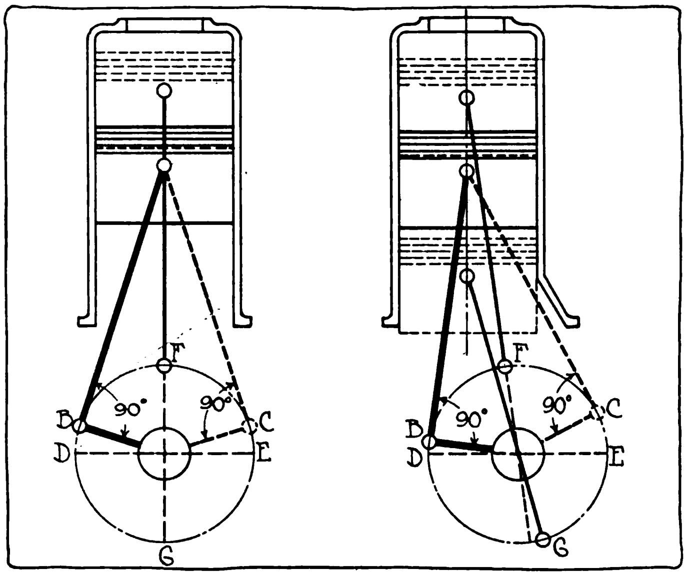

Fig. 0—Diagram indicating relations of primary and secondary forces causing unbalancing of mass. To the right: Same in the case of offset shaft

together in the V-type engine, the secondary forces of each set are unbalanced, and their resultant is 40 per cent. greater than either and acts in a horizontal plane, Fig. 5.

The secondary forces of the four-cylinder engine, Fig. 4, result from the fact that the common center of gravity of the four pistons, instead of being stationary, as would be the case if the connecting-rods were infinitely long, has a small harmonic motion of double frequency. It can therefore be balanced by reciprocating or rotating balance weights driven at twice the frequency of the main piston.

Lanchester's ingenious method of doing this consists in gearing a pair of wheels carrying balance weights to the main crankshaft, which drives them at double its speed and in opposite directions. The centrifugal forces of the weights balance themselves in the plane through the axes of the wheels, and they have a vertical component balancing against the secondary forces.

In four-cylinder motors of the two-cycle type the cranks can be placed at right angles, and it is then possible to secure complete balance of both primary and secondary forces, with the exception of a tendency to rock the motor lengthwise produced by the secondary forces. This can usually be absorbed in the chassis, where the question is of automobiles. Five- and six-cylinder motors of either four- or two-cycle type can be perfectly balanced with regard to the primary and almost perfectly with regard to the secondary mass effects.

To sum up, the motors in common use which may run without vibration when driven from an external source are only the following: The motor with rotating cylinders, ordinary five- and six-cylinder motors and four-cylinder two-cycle motors with the cranks at right angles. But, when the crankshaft is long, in any of these, it is difficult to make it so rigid that the motor will not tend to vibrate relatively to its flywheel, whose mass center remains almost stationary.

Balance of Impulse

Mere balance of mass is however insufficient to produce a vibrationless motor in practice, because, in considering it, no account is taken of the violently fluctuating pressures in the cylinders and the consequent strains in the crankshaft and the motor framing. These strains must be balanced so as to have no tendency to shift the center of gravity of the motor relatively to its crankshaft and points of support.

In Fig. 1, if the cylinders are in line and fire simultaneously with equal charges, there will be no tendency for the motor to move, except, by torque reaction, around the crankshaft, and the design of Fig. 2 secures this result more simply, the piston pressures being necessarily equal. The well-known valveless two-cycle Junker motor Fig. 6, has equality of impulse, but the secondary mass forces are unbalanced. The three cranks of each cylinder receive simultaneous impulses once only per revolution. The crankshaft receives therefore virtually one impulse for every half-revolution. In fact, in this, as in all single-acting motors, the pressures on the pistons during the compression and explosion strokes twist the crankshaft first backward and then forward, producing a severe condition of stress, while the reactions of the cross-heads also alternate in direction with each stroke.

If a second pair of cylinders, each with a pair of pistons, were arranged tandem on top of the first two, making each tandem line double-acting, the cranks of the two sets could be placed at right angles and the balancing of both impulse and mass would be almost perfected, but a motor of this description has great height and many parts, and the same results can be obtained by the author's arrangement shown in Fig. 7.

In this, two open-ended cylinders, each with a pair of opposed pistons, are placed closely together, side by side, and the upper piston of one cylinder is connected to the lower piston of the other by a pair of external oblique tie-rods, as shown. An explosion between A and B drives B down and A up, also drawing up D by the oblique rods, and gives two equal and opposite impulses to the two cranks. The explosion in one cylinder compresses the charge in the other, as the motor operates on the two-cycle plan, the pistons at the ends of their strokes uncovering inlet and exhaust ports, as in the Junker-Oechelhauser arrangement of Fig. 6.

The complete motor has two such pairs of cylinders and a

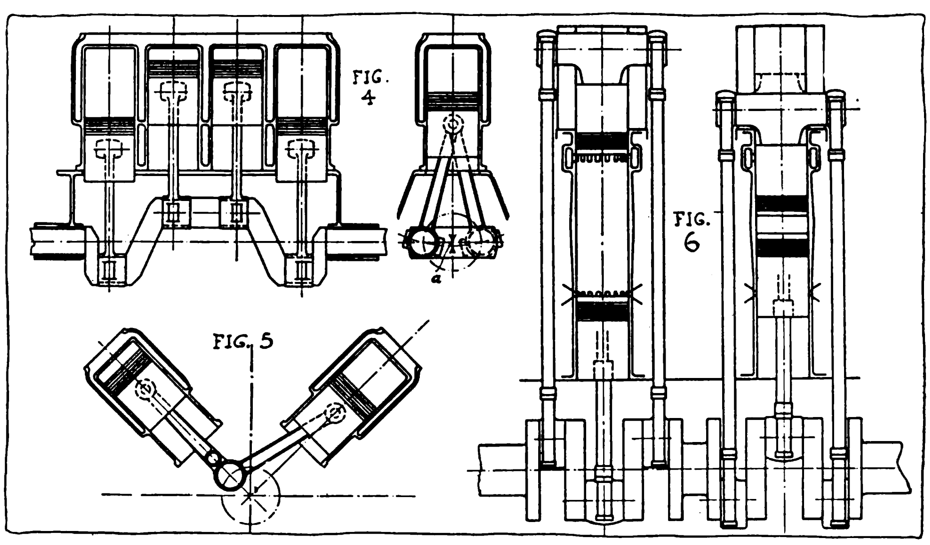

Fig. 4—Ordinary four-cylinder motor; secondary forces unbalanced. Fig. 5—Eight-cylinder V-motor; secondary forces unbalanced. Fig. 6—Junker-Oechelhauser motor; impulse and primary forces balanced; secondary unbalanced

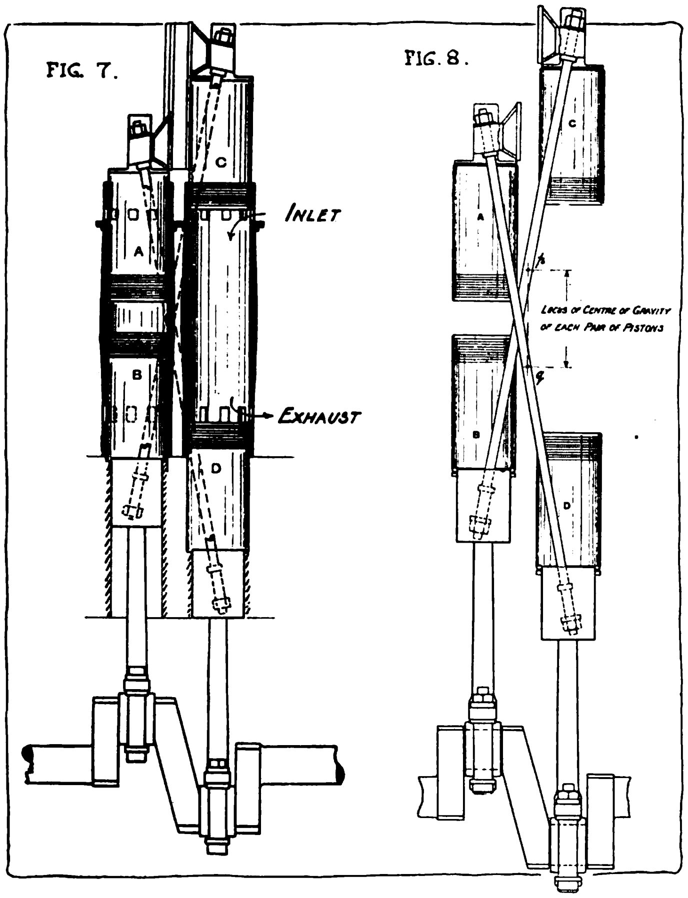

Figs. 7 and 8—Fullagar motor. Mass balanced, both primary and secondary. Impulse balanced if motor is made with four cranks

second pair of cranks at right angles to the first, and the explosions in the four cylinders, acting upon the eight pistons, thus produce eight impulses per revolution. The vertical forces at all times balance each other and are not transmitted through the engine frame.

The pistons of each pair are rigidly joined and form one moving part, as shown in Fig. 8. The center of gravity of the pistons A and D is at the point q and travels up and down on the line pq, while the center of gravity of the other pair of connected pistons, C and B, is at the point p and travels up and down on the same line. The primary forces are thus perfectly balanced. Secondary forces result from the fact that the common center of gravity of all four pistons and their connecting-rods oscillates on the line pq with an amplitude which, with a connecting-rod of the length of five cranks, is equal to 1-20 of the stroke of each piston, but this force is balanced by the corresponding force in the other pair of cylinders, and as the two pairs of cylinders are brought closely together, the secondary couple which alone remains, is small. In a six-cylinder motor of the type it could be nil.

The only reactions on the frames of the Fullagar motor are the horizontal thrusts of the crossheads on their guides, and these are always in one direction. A 500-horsepower motor of this type, with 12-inch bores and 18-inch stroke, has been in operation for one year and at 250 revolutions per minute, which means an average piston speed of 750 feet per minute, develops scarcely any perceptible vibration. Even at 900 feet piston speed the vibration is still slight. The oblique rods cause little friction, as the angle of the rods is less than the maximum angle of the connecting-rods, and the total friction in the motor is less than it would be if each of the eight pistons had its own crank and connecting-rod. While the balance of mass and impulse is very good, there is, however, one unbalanced reaction of the motor, each successive impulse tending to rotate the motor backward around its crankshaft, and there is also the gyrostatic effect of the flywheel, which in the case of application to aeroplanes it might be desirable to eliminate.

The only extensively used motor in which the torque balance, just referred to, has been effected together with good balancing of mass is that which was fitted to Lanchester cars in 1896. As shown in Fig. 9, the primary forces were here balanced by weights on the crankshafts, the secondary forces of the pistons balance themselves, and the torque balance was secured by oppositely rotating flywheels. Balance of impulse was not obtained.

A motor which secures perfect balance of all forces is shown in Fig. 10. Two opposed pistons in a single cylinder are connected to two oppositely moving crankshafts at opposite ends of the motor. The shafts need of course to be kept in co-ordination by a layshaft and screwgears or by a pitch-chain and spurgears, though such a connection has to perform no appreciable work under normal operation. The arrangement has the advantage, for aviation purposes, that two propellers can be driven directly. If two such cylinders are placed side by side and their connecting-rods are coupled to opposite cranks, these rods will then balance each other, and perfect balance of all forces—mass, impulse, torque and gyrostatic effect—will be secured.

By applying the two-shaft principle to the Fullagar cross-connected cylinder construction, Fig. 7, a two-cycle and double-acting motor is produced in which each crank receives two impulses per revolution. An improved arrangement for this purpose is indicated in Fig. 11, where a pair of cylinders with cross-connected pistons is arranged in a plane at right angles to that of the shafts. Two such pairs can be side by side when the cranks are at right angles. Small balance wheels will then be needed to balance the connecting-rods,

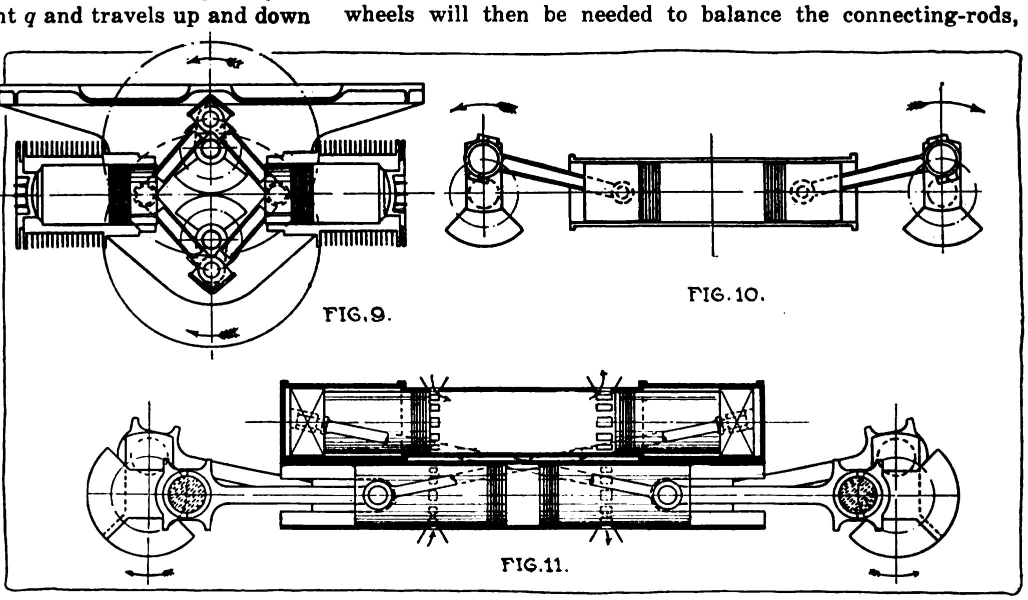

Fig. 9—Mass and torque balanced; impulse unbalanced. Fig. 10—General scheme of two-shaft motor with mass, impulse, torque and gyrostatic action balanced. Fig. 11—Double-acting valveless motor with two shafts and four impulses per shaft per revolution; perfect balance of all five kinds

and four impulses will be transmitted to each crankshaft per revolution. As the cylinders in either case work on two-cycle, an air pump of some kind is required, and in the illustration the two crossheads of each upper cylinder are arranged to act as blowers—a method found satisfactory.

The Improvement of Spring Suspension

An Examination of the Forces and Movements to which Motor Vehicles Are Subject on the Road and of the Cushioning Devices in Use or Required

By M. C. K.

COMMON unlearned ingenuity and plodding experimental metallurgy share the honors for most of the advancements which have been made in means for cushioning motor vehicles and their occupants against road shocks since the early days when ordinary vehicle springs were accepted as the only available basis for any new development that might be found necessary. Of systematic unfolding of scientific principles, like those which have governed the evolution of motors, there has been little question. No assistance has come from co-operation of investigators or the publication of indisputable data, excepting only the improvements which have been gradually made in the qualities of spring steels and their heat treatment, some of which have been duly tested and recorded. And the principal reason for the wild growth by which the present stage in the "springing" of motor vehicles has been reached, is easily discovered in the fact that it has always been the requirements which were in doubt rather than the means for meeting them.

The requirements are indeed most difficult to ascertain and express, covering an endless variety of conditions, due to the interactions among road, load and speed variations, further complicated by other interactions between springs and elastic tires. The problem of meeting requirements which cannot be specified naturally eludes a systematic and scientific solution, while it appeals to ingenuity and invites compromise, and it is therefore quite consistent with the intrinsic facts of the situation when the present status of the art seems to be characterized by a great multiplicity of loosely related auxiliary devices, all intended to obviate the shortcomings of the standard combination of vehicle leaf springs and elastic tires and representing a corresponding diversity of opinions as to what these shortcomings are.

While in recent years the vehicle springs proper have been modified in several ways—mainly by introducing a rocking motion around their thickest portion, as in cantilever springs, and by trussing two springs to combine strength with flexibility—these modifications have not yet been fully accepted as improvements or widely adopted; neither can it be said that auxiliary devices have been rendered superfluous by them, as, on the contrary, they continue to be used in connection with them.

Mechanical Requirements Never Defined

So long as nobody has yet been able to formulate sharply and precisely the mechanical actions required of a spring suspension for motor vehicles, no marked unity of efforts toward its improvement or standardization can evidently be expected. Furthermore, the mitigation of shocks, which in the widest term is the object of a spring suspension, is in itself a compromise action from which nothing absolute but only the alleviation of an undesirable effect is demanded. The whole foundation for a discussion of spring suspension principles and devices is therefore still largely one of personal opinion, with only here and there scientifically established facts and laws for guidance, and the most urgent need for making such a discussion fruitful is to get the requirements of a spring suspension formulated in terms of mechanical motion and as closely as possible to the essentials; and these, it may be said in advance, may differ for different classes of vehicles. The great difficulty is to narrow these requirements down to a working basis so well defined that the mechanical elements in any spring suspension stand in clear relations to them, and yet to have them wide enough to meet with general approval among those most competent to judge. Some general views on the whole subject and its relations to motor vehicle economy and motor vehicle manufacture seem here to be needed in order to make it clear that such a formulation of the essential requirements is desirable as well as possible, as the difficult nature of spring suspension mechanics and the resulting lack of a literature on the subject—excepting always the metallurgical end of it—have made it appear fairly satisfactory to many to go on stumbling toward final solutions rather than attempting a short cut through a systematic standardization of opinions and practical developments.

General Viewpoints—Relations to Economy

In the matter of economy to the user, the motor vehicle industry aims of course for nothing less in the end than to get back to first cost of transportation by animals, with maintenance expense much smaller, the life of vehicles at

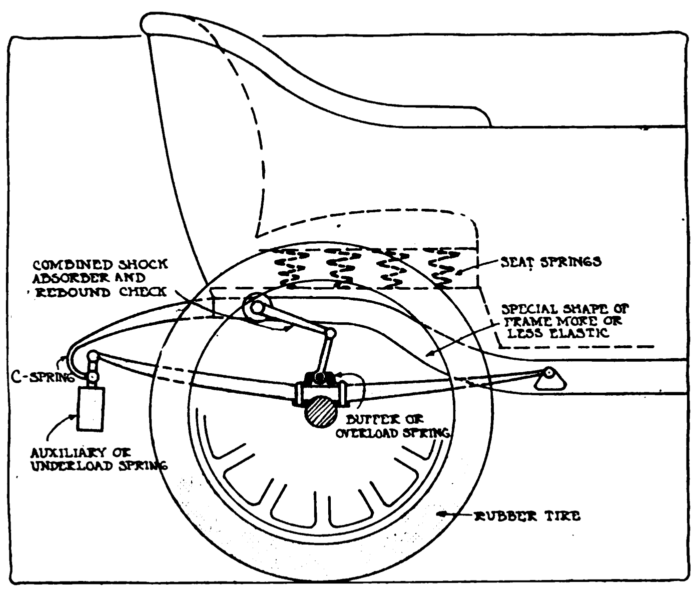

Fig. 1—Diagrams of main organs in modern spring suspension for rear end of a motor vehicle

least trebled by means of suitable repairs, as compared with the average life of draft animals, the speed at least doubled and the daily mileage quadrupled. This aim was taken for granted at the beginning of the industry, and belief in the possibility of realizing it, especially with regard to first cost and maintenance, was the principal motive for creating the industry. It was only later that speed was discovered to be the principal factor which actually operated in practice to make the use of motor vehicles broadly economical through the saving of time.

The great efforts made in the past few years for introducing economies by other means show, however, that an economical diet consisting of speed alone cannot be considered wholesome. Thousands of forms of transportation exist to which speed cannot be applied, and in these complete economy must come by more natural means. Also much doubt is caused by basing claims for economy on speed, as a high velocity over uneven ground is always more or less destructive and it is difficult to tell where the advantages of wage saving and of business efficiency begin to overbalance losses due to deterioration and repairs. Many hold that speed is already overdone and constitutes a public nuisance, which eventually must be checked. On the whole, the trend of opinion is perhaps toward the idea that speed must in the end become the free gift of motordom to the world rather than a commodity to be sold at the highest possible price. This implies that speed in moderation, yet far higher than any for which ordinary vehicle springs were intended, will always be practiced, and that speed in still higher degree must remain for nearly all vehicles a reserve property, to be utilized in emergencies without severe economical punishment.

Fundamental—and Needs Publicity

In the sharp economical development which has been inaugurated and which bids fair to become sharper yet, there will thus be no possibility for neglecting the improvement of spring suspensions, if it is admitted that speed cannot be much abated and that the present relatively high maintenance cost of motor vehicles is closely associated with their shortcomings in this respect. Among other subjects worth studying with a view to the increased economy so peremptorily demanded, that of spring suspensions, including tires, claims most public attention, because it is least recognized among engineering elements and is yet truly fundamental, deeply affecting durability, practicable speed, tires and tire wear, fuel consumption—in fact all the main factors in mechanical economy—besides being the principal one to be considered in the matter of producing driving comfort and security for frail loads.

The great variety of spring suspension schemes and devices which are in the market and, in the aggregate, very extensively used, speak of course loudly enough, if not very articulately, of the great economical importance of improved methods for cushioning against road shocks, but each of them is offered with the claim that it remedies the shortcomings as much as is needed, in one respect or another if not in all respects, and is therefore actually set up as an argument against the need of further discussion. And a similar pressure upon public opinion, making for silence where speech would be more profitable for the general advancement, comes from manufacturers of automobiles and of tires who never cease to warn against the economical dangers of overloads, holding themselves free from responsibility for tire and spring injuries if overloads are carried. By constant repetition of a warning which is in fact completely justified by the actually existing conditions, they have conveyed an impression to the effect that the user is at fault if he overloads—this being so far correct—but this impression is through the imperfections of average logic construed to imply that the manufacturers and the spring suspensions, including the tires, are all that could be expected and that consequently all discussion with regard to urgent improvement would be wasted, at least so long as one opinion is as good as another, in the absence of generally recognized requirements and means for meeting them.

A keener demand for economy must eventually result in recognition of the business fact that overloads are everywhere carried occasionally as a matter of necessity and that spring suspensions or tires which do not respond to this necessity are to that extent in need of improvement, a large margin being required for load variations as well as for speed variations. That the factor of safety should be permitted to be smaller—5 to 10 times smaller—in this respect than for any of the simple mechanical elements in the construction of an automobile or motor truck, is scarcely a proposition for which approval can be expected throughout the future of the automobile industry. The problem must therefore be faced as soon as possible in theory, in order that practice shall not find itself too far behind popular demands.

Before the mechanical requirements of a spring suspension can be formulated, it may be useful to pass in review the objects which it must serve, as some of these are otherwise easily overlooked. In widest generality it may be said that a spring suspension serves comfort under small shocks and security under sharp ones. More in detail the objects may perhaps be listed as follows:

(1) Protection; (a) for machinery and values, (b) for persons.

(2) Comfort; (a) in general, (b) to make driver's job less wearing, (c) to subserve safety by keeping the faculties unimpaired.

(3) Fuel economy; by reducing load lift and tire flexions.

(4) Speed; since protection, comfort and personal safety determine the speed limits under average American road conditions.

(5) Reserve speed; which, when permissible, enlarges the range of usefulness of each vehicle and reduces investment.

(6) Racing speed; an artificial requirement but important to demonstrate, among other things, the fitness of a spring suspension in its totality.

Present Complication

The equipment which has been developed gradually to serve all of these purposes already comprises a considerable number of additions to the simple springs which were found sufficient for the more slowly moving vehicles of the past. Fig. 1 presents a diagrammatic view of the organs now found necessary for a complete spring suspension at one end of a vehicle. Spring washers to prevent bolts from jarring loose throughout the vehicle structure come under the same head, and, if the front end of a vehicle is usually suspended a trifle more simply, this is mainly because the standard steering system is influenced unfavorably by large spring action. On the other hand, it is found necessary to give radiators at the front of motor trucks a special spring suspension, and in some cases it is deemed desirable also to hang the motor in a special spring frame. The whole equipment represents a considerable quota of the original cost of a vehicle, while the shortcomings still remaining in it, despite its elaborateness, stand for a much larger quota of upkeep expenses. Simplification would plainly be desirable if consistent with improvement. For convenience in reference a list of the organs or factors which enter into a complete modern spring suspension follows:

(1) Air tires; with solid rubber tires second choice and solid tires plus elastic wheels third choice.

(2) Alloy-steel vehicle leaf springs; either (a) long, strong and very flexible or (b) supplemented by auxiliary coil springs.

(3) Auxiliary coil springs; in all cases when the leaf springs, for economical or other reasons, are chosen stiffer than they are required to be for easy riding.

(4) Rebound checks; always required to remedy an intrinsic shortcoming in the strength of a leaf spring and to limit movements of the vehicle body under certain road shocks of a certain kind. They are often combined with

(5) Spring dampers, commonly termed shock absorbers, though this term is proprietary; always more or less useful if the leaf springs are flexible enough—alone or in combination with the auxiliary coil springs—to be efficient for comfort.

(6) Overload springs or buffers.

(7) C-springs; while apparently a fashion feature they maintain their necessity because they produce a longitudinal cushioning effect at stops and starts and also a lateral and

Chevrolet Continues Four and Six

Six Reduced to $1,425 and New Body Fitted—Four Has 106-Inch Wheelbase and Bigger Brakes

CHEVROLET for 1915 continues to make the two chassis which have been marketed for 1914. These are a four and a six, the latter coming out at last year's automobile shows. The price of this six, which comes only in touring form, has been cut from $1,475 to $1,425. On the four-cylinder chassis, Chevrolet puts a re-designed, streamline five-passenger body, calls the car the Baby Grand and sells it for $875. Or, it fits an attractive roadster body, designates the model the Royal Mail and continues to offer it at $750. With the Auto-Lite electrical system the four sells for $110 more.

The principal changes in the four-cylinder car are the wheelbase increase from 104 to 106 inches, and the making of more powerful brakes by enlarging their diameter 2 inches, making them 12 inches. Mechanically, the six is practically unchanged, but it has a new sloping body, which is roomier than that formerly used.

The six-cylinder motor is an L-head 3 5-16 by 5 1-4, with cylinders in blocks of three. Thermo-syphon cooling, constant level splash oiling, and Remy dual ignition are features of this power plant. The driveshaft is inclosed in a torsion tube, bolting at its rear end to the gearbox, the latter being in unit with the rear axle, which is three-quarter floating. Other specifications include cone clutch, platform rear spring suspension, left drive, center control and rear gasoline tank feeding by pressure.

The wheelbase of the six is 112 inches, tires are 34 by 4 and Auto-Lite cranking and lighting are furnished.

The fours have the distinctive Chevrolet motor with valves in the head, rockers and springs inclosed within an aluminum cover plate. Twenty-four horsepower is credited to the engine, whose dimensions are 3 11-16 by 4 inches. The cylinder head is a one-piece casting secured to the cylinder block by bolts, making a compact and readily removable assembly.

Rear Springs Take Drive

Drive is through a cone clutch to a three-speed gearset located amidships on two frame cross members. Final drive is by double universal uninclosed shaft, torque being taken by a rod and drive by the rear springs, which are three-quarter elliptic. Tires are 32 by 3 1-2 on both roadster and touring car.

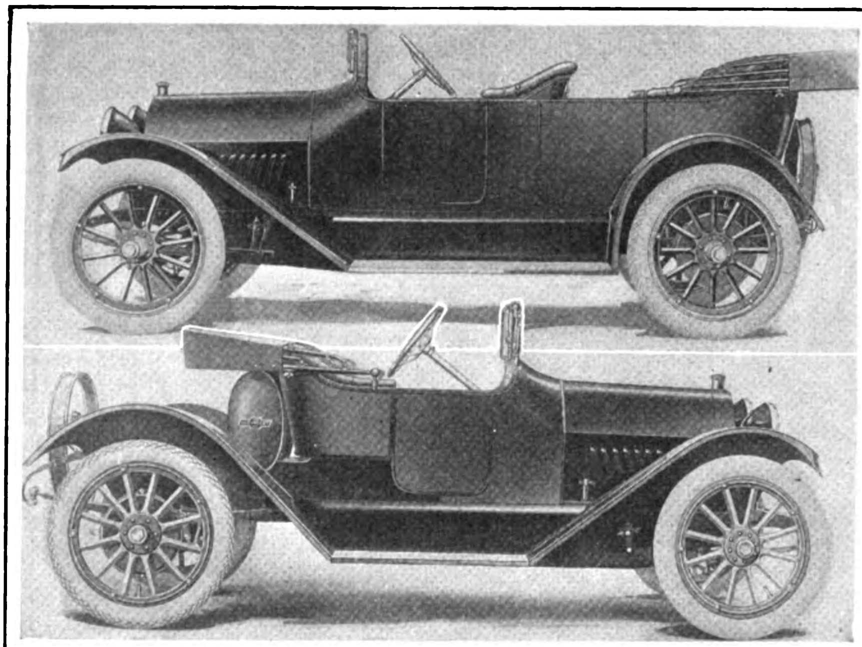
The Chevrolet Four

The valve-in-head type of engine which propels the four-cylinder roadster and touring car has a displacement of 170.9 cubic inches, and its stroke-bore ratio is 1.08 with an S. A. E. horsepower rating of 21.8.

The cylinders are cast in block form, with the upper half of the crankcase integral with them. The joint at the base of the cylinders is thus eliminated, resistance load being spanned to the crankcase walls and bearings through continuous webs placed so as to distribute the strain. This is reduced on each cylinder individually because of the support given by the adjoining cylinder.

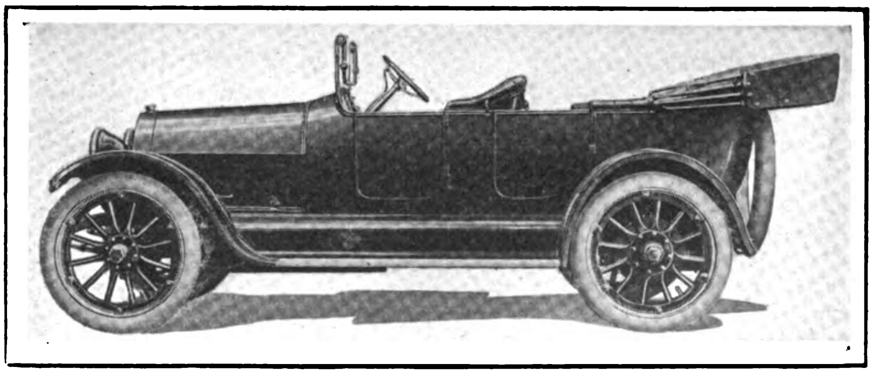
Detachable Cylinder Head

The head is a one-piece casting secured to the cylinder block by bolts, the joint being made with a copper and asbestos gasket. The special advantage of the separate head

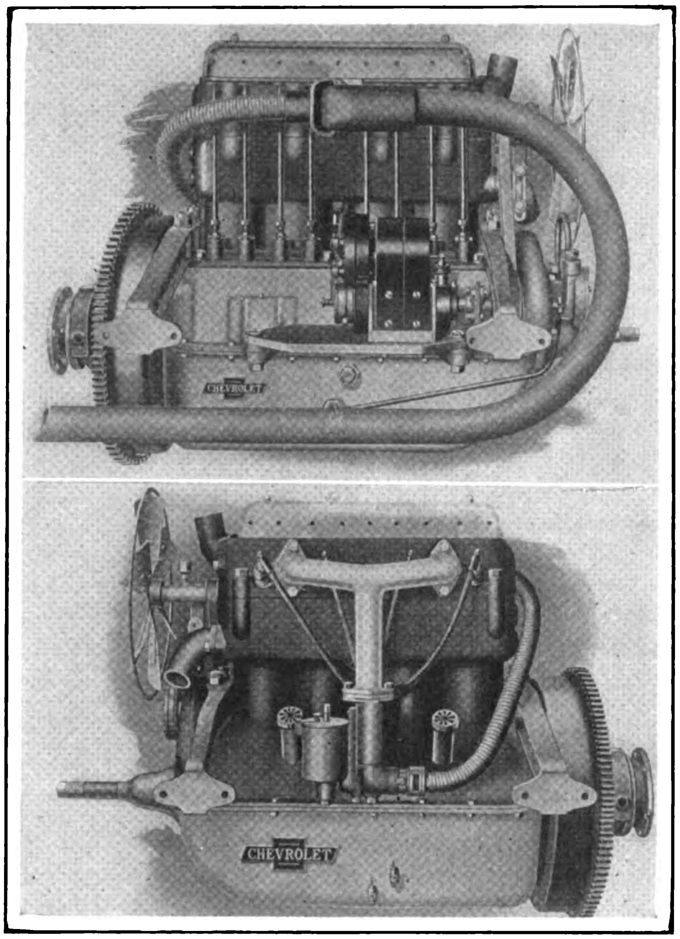


Upper—Four-cylinder Chevrolet Baby Grand touring car, which, with 106-inch wheelbase and full equipment, except electric starting and lighting, sells for $875. The Auto-Lite electrical system is furnished for $110 extra

Lower—Chevrolet Royal Mail roadster, which is mounted on the same four-cylinder chassis as the Baby Grand, and sells for $750 without electric starting and lighting, which is furnished at $110 extra



Six-cylinder Chevrolet, which has a 26.3-horsepower motor, 112-inch wheelbase and a new roomy body. The Auto-Lite electrical system is furnished at the stock price, $1,425



Upper—Exhaust side of Chevrolet four-cylinder motor, showing the mounting of high-tension magneto and hot air intake for carbureter. Note exhaust passing forward, down and back
Lower—Intake side of same motor showing carbureter mounting and connection of hot air intake. Note detachable cylinder head inclosing overhead valves. Flywheel is ready for gearing to Auto-Lite electrical system which is furnished at $110 extra on the four-cylinder cars

construction is that, being readily removable, access to valves and combustion chambers is an easy matter. The valves are carried in the head piece without cages, which allows efficient cooling of both valves and their stems, they being entirely surrounded by water. The plugs are also set at a convenient angle in the head casting on the right side.

A compact and neat appearance is given the engine assembly, due to the housing of the rockers and springs within an aluminum cover plate fitting to the cylinder head and held in place by a bolt at either end. Besides keeping out dirt, this also has the effect of silencing the valve actions. When the cover is in place, only the valve rods running down to the tappets on the right side are visible.

Gearbox Mounted Separately

The engine is not of the unit power plant type, but has exposed flywheel with gearbox separately mounted further back. The motor supports are at front and rear of the cylinder casting, and are in the form of arches from which the assembly is hung by bolts. These arched arms attach to the side frame rails.

The carbureter, which is a 1-inch Zenith, double-jet type, is placed on the left side and has a Y-shaped intake. The vaporization of the fuel is augmented by the utilization of heated air taken from a jacket on the exhaust manifold and conveyed through a flexible tube to the air intake. A shelf on the right carries the Simms high-tension magneto which is driven by a shaft connecting to the camshaft drive through helical gearing completely housed at the front of the motor.

On the touring model only, the gasoline tank is placed at the rear of the chassis, and instead of having pressure feed to the carbureter, the Stewart vacuum feed system is employed. The vacuum tank is mounted on the vertical portion of the intake manifold so that its feed to the carbureter is almost vertically downward. On the roadster model, this vacuum supply is not required, as a positive gravity feed is attained by placing the main supply tank on the rear deck, it being high enough above the carbureter to insure a good flow.

Internally, the Chevrolet four-cylinder motor presents no unusual features but adheres to approved design. The crankshaft is a three-bearing type running on die-cast babbitt bearings with the center one brass backed. The connecting-rod bearings are also brass backed, and are drop forgings with strap ends. The camshaft is also a three-bearing construction with integral cams, the bearings being of the plain type. This shaft is driven by a helical gear which bolts to its shaft.

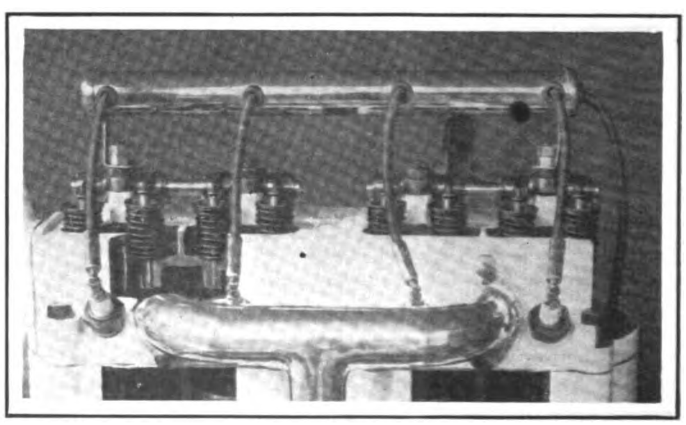
The cooling system is of the thermo-syphon type incorporating the usual belt-driven fan and radiator of large capacity.

The lubrication, ever an important part, is well worked out. The system is a self-contained, constant level splash type with the oil circulated by a gear pump which takes the supply from the lowest part of the crankcase and after forcing it through the dash sight feed, sends it back to a distributing pipe inclosed within the crankcase. This distributer delivers the oil to the individual oil troughs, into which the connecting-rod ends dip at each stroke. All bearings have oil grooves, while the crankshaft bearings are supplied from pockets in the crankcase casting above the bearings. These pockets receive their oil from the splash action. The camshaft bearings are oiled by wicking from the crankshaft bearing pockets.

Two-Unit Electrical System

The Auto-Lite cranking and lighting system, which is supplied at extra cost, is of the two-unit type, an electric motor connecting through the Bendix drive with teeth in the flywheel rim serving for turning the crankshaft, and a separate generator driven by helical gearing and carried on the right providing current for lighting and ignition. The latter has in unit with it a Connecticut coil and distributer to take care of the ignition, it replacing the magneto equipment when the electrical system is supplied. The storage battery used is a Willard, while the headlights are of the two-bulb form, eliminating side lamps. The cranking motor, when fitted, occupies a position to the right of the flywheel, being hung from a frame cross arm.

The drive features include a cone clutch of ample proportions. This acts in the flywheel and has leather facing with springs underneath. The cone is of pressed steel and there-



Upper part of Chevrolet four motor, showing overhead valves which are inclosed as illustrated at the upper left of the page fore light and strong. The gearset is carried amidships on two frame cross members. It gives three forward speeds and reverse. The main shaft is carried on annular ball bearings while the countershaft revolves on plain bronze bearings. The gearshifting lever is placed directly above, so that an efficient center control is provided.

Semi-Floating Rear Axle

The propeller shaft is of the open type fitted with two universals with the torque taken by a torque arm and drive by the leaves of the substantial rear springs. The rear axle is of semi-floating construction with its heat treated shafts running on Hyatt roller bearings. The housing is malleable, and is split crosswise. The gear ratio is 4 to 1. The outer ends of the axle tubes carry the brake shafts operating the internal expanding emergency and external contracting service brakes which act upon 12-inch drums 1 3-4 inches wide.

The rear springs are of three-quarter type and mounted outside of the frame rails. They are 48 inches in length and have scroll rear ends. The front pair are 36 inches long, while all leaves are 1 1-2 in width.

A 17-inch wheel controls the steering gear, which is on the left. This gear is of the worm and worm gear type, adjustable. It incorporates ball thrust bearings to take the thrust load.

The equipment of both roadster and touring car includes everything now looked upon as a standard part of the modern automobile, and is ready for the road.

The Six-Cylinder Model

There is very little in common between the chassis design of the six and the fours already described. The motor with its dimensions of 3 5-16 by 5 1-4 delivers 26.3 horsepower by S.A.E. formula, has a displacement of 271.5 cubic inches, and its stroke-bore ratio is 1.58. The cylinders are cast in blocks of three of L-head type, valves being on the right. The crankcase is a two-part, horizontally split design with the cylinder blocks bolting to the upper half of the case.

This engine has the same method of support in the frame as the four, there being arched cross arms from which front and rear of the crankcase are hung by bolts. Arranged on the right side are the exhaust manifold and the three electrical units for ignition, cranking and current generating, crankcase brackets carrying them. The Zenith double jet, horizontal carbureter is placed on the opposite side, there being little or no external intake manifold, connections to the adjacent corners of the cylinder blocks providing entrance to the passages within the castings.

Thermo-Syphon Cooling

The cooling is by thermo-syphon in connection with a five-blade, belt-driven fan. Oiling is a constant level splash arrangement with circulation maintained by a plunger pump, operated by a camshaft eccentric. The oil reservoir is an integral part of the lower half of the crankcase, on the right rear side.

Like the four, the main bearings of the crankshaft, which are three in number, and the connecting-rod bearings, are of die cast babbitt brass backed. The camshaft, a drop forging with integral cams, has three plain bearings and is operated by helical gear connection with the crankshaft.

The shaft on the right, which is also driven by helical gears, drives the Auto-Lite generator, and back of it the Remy dual magneto, through universal joint connection. The cranking motor, also an Auto-Lite, is mounted so that its gears will shift into mesh with the flywheel face teeth when the pedal is pressed. This pedal not only makes the gear connection but sends the current to the motor. The storage battery is a 6-volt Willard.

The final drive after it leaves the cone clutch is through a propeller shaft inclosed within a torsion tube. In this construction, only one universal is used, that being ahead of the point where the shaft enters the tube. This tube takes both drive and torque, and is braced by radius rods running from its front end diagonally out to the ends of the axle tubes.

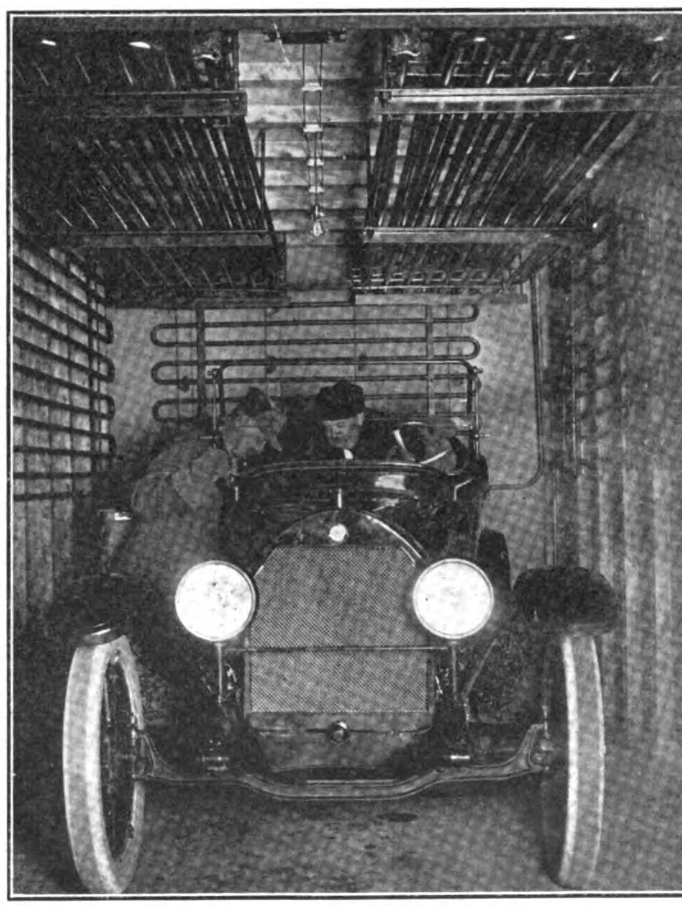
The gearbox is a part of the final drive unit, being interposed between the end of the tube and the axle housing, flanges connecting all three to make a unit. This gearset has three selective speeds and reverse, while the axle is three-quarter floating.

The rear spring suspension departs radically also from that of the four, as it is of the platform type, in which a transverse half-elliptic crass spring shackles at its ends to the rear ends of two other half-elliptics. These parallel the side frame rails, attach to the axle at their centers and shackle to frame brackets at the front ends. The center of the rear cross spring attaches to the frame rear cross member.

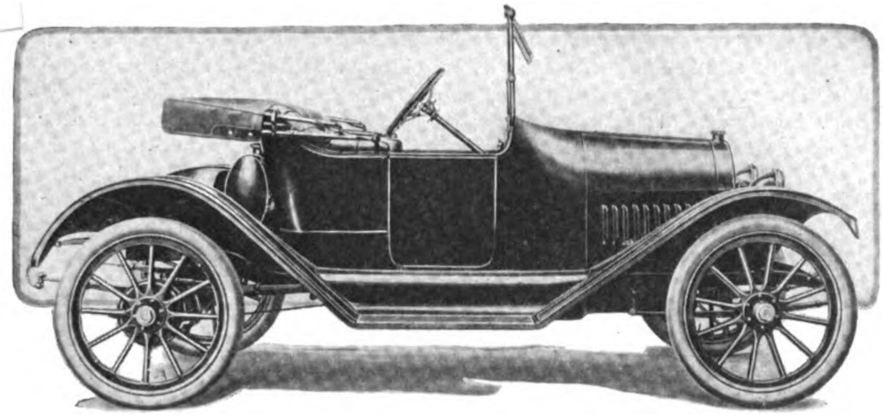
This construction serves as a protection for the 15 1-2-gallon fuel tank hung from the rear of the chassis. Gasoline is fed to the engine under pressure.

Drive is on the left, control in the center and the equipment is complete. Some motor dimensions follow:

Part	Four	Six
Crankshaft:		
Front bearing..........	2 3-4 by 1 1-2	3 by 2 3-16
Center bearing.........	2 by 1 31-32	2 5-8 by 2 7-32
Rear bearing...........	3 1-8 by 2	3 3-4 by 2 7-32
Camshaft:		
Front bearing..........	2 9-16 by 1 5-16	2 9-16 by 1 3-4
Center bearing.........	2 by 1 11-16	2 3-8 by 1 11-16
Rear bearing...........	1 7-8 by 1 1-4	2 by 1 1-4
Valve diameter...........	1 1-2	1 1-8
Connecting-rod bearing..	2 1-8 by 1 1-2	2 3-8 by 1 11-16



The Thomas B. Jeffery Co. has recently installed at Kenosha, Wisconsin, a refrigerating plant for the purpose of making cold weather tests on carbureters, batteries and motors. In an hour after starting the refrigerating machinery, it is possible to get a temperature of from 8 to 10 degrees below zero. The room in which this outfit is installed will accommodate the largest models and leaves plenty of room for men to work on the car



New Monroe roadster, which sells for $460 with equipment

Monroe Two-Passenger Car $460, Equipped

Top and Windshield—Electric Lights—Unit Power Plant Standard Parts Throughout

A TWO-PASSENGER 20-horsepower roadster selling for $460 with complete equipment has been announced by the Monroe Motor Car Co., Flint, Mich. The car is of standard design throughout, has pleasing lines and the equipment includes all the ordinary accessories except a starting motor of Auto-Lite make which is $35 extra. Two electric headlights and a tail light are fitted, the current being supplied by an Auto-Lite generator and an L.B.A. storage battery. The top is mohair and has a full set of side curtains and a dust cover. A two-piece, double-ventilating rain-vision windshield has been adopted and there is an electric horn, tire pump and tool kit to complete the equipment.

Thirty Miles per Gallon

Thirty by 3-inch Goodyear clincher tires are used and the wheelbase is 96 inches with standard tread. A speed of from 3 to 50 miles per hour is claimed for this car and the gasoline consumption is stated to be 30 miles per gallon.

The motor is a unit power plant construction suspended at three points. The four cylinders are cast in a block. The valves are in the head which is removable. The bore of the motor is 3 inches and the stroke 3.75, giving an S. A. E. rating of 14.4. Power is transmitted through a 10.5-inch cone clutch to a three-speed selective gearset. The flywheel is exposed and the gearset is connected to the motor by means of two arms which pass around each side of the flywheel.

The electric generator is situated on the right hand side of the motor at the forward end and is driven from the timing gear case by a helical gear. Ignition is supplied by a Connecticut automatic system, the electrical energy being taken from the storage battery. This unit is located directly in front of the lighting generator and is driven by helical gears.

When a starting motor is fitted it is also placed on this side of the motor and drives through teeth which are cut in the rim of the flywheel. The release of the pinion is accomplished by the Bendix helical drive. In this drive the pinion is mounted on a helically cut shaft so that when the starting motor is driving the engine, the pinion tends to slide forward as far as possible and thus holds itself in mesh with the flywheel gear, but when the drive is in the opposite direction the gear slides back out of mesh.

The camshaft is situated on the right side of the motor and operates the valves through a conventional rocker arm construction. The head is held down by seven nuts.

On the right side of the motor is found the Zenith carbureter to which there is a flexible tube connected with a hot air stove on the exhaust pipe. An unusual arrangement is noted in the method of carrying away the exhaust gases. The exhaust pipe is attached to the rear of the casting.

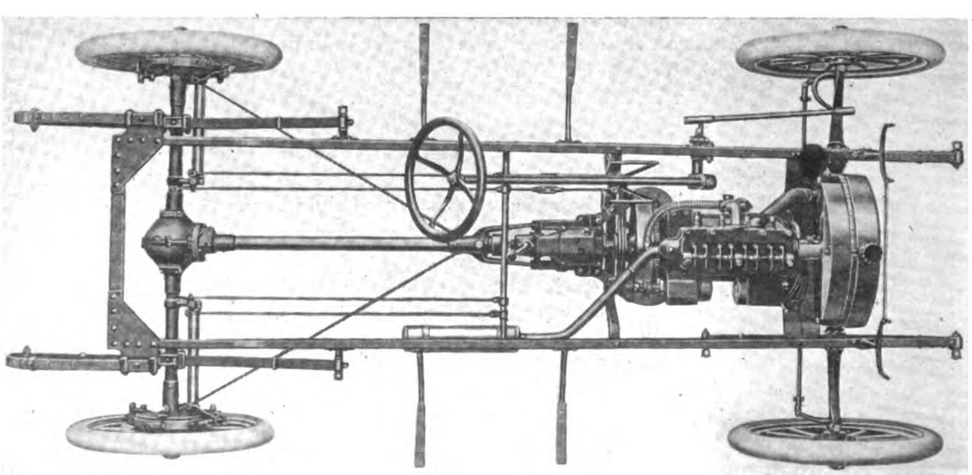
Cooling is by means of the thermo-syphon system. A honeycomb radiator with an auxiliary tank at the top is used, the circulation of air through it being aided by a belt-driven fan. The lower connection to the motor is a large diameter hose which enters on the left side near the front, while the return connection to the radiator is at the front end of the motor at the top and in the center.

Two Main Bearings

The spark plugs are S. A. E. Standard and are situated on the left side and are horizontally placed. The valves are 1.375 inches in diameter. Two main bearings are employed, the front one being 1.5 by 2.5 inches and the rear 1.625, by 2.5 inches. The camshaft bearings are both 1.4375 by 2.75 inches. Helical timing gears are used.

Lubrication is by a pump and splash system, the pump delivering oil to all the rods, bearings and timing gears. The crankcase is provided with a reservoir and there are individual troughs into which the connecting rods dip. The oil level is shown by a float in the breather tube.

Double heat-treated nickel steel gears, carried on ball bearings throughout are found in the gearset. The shifting lever is mounted conveniently at the rear of this unit.



Plan of chassis, showing unit power plant and location of accessories

The rear construction consists of a semi-floating rear axle with a torque tube which is attached to the rear of the gearset by means of a yoke. This complete unit is reinforced by rods running from the yoke to the axle ends.

A bevel gear reduction of four to one is standard. New departure bearings carry the differential gears and Hyatt roller bearings are used on the axle shaft and main drive shaft. Adjustment of the differential and pinion gear can be made outside of the axle thus obviating the necessity of disassembling the axle.

Internal expanding and external contracting, toggle-operated brakes operating on 10 by 1.25-inch hubs are used. Brakes are lined with Thermoid hydraulic compressed brake lining. The service set is actuated by the clutch pedal and the emergency by another pedal which has a ratchet for locking it.

Half elliptic springs, 36 inches long, are fitted in the front and 3-4 elliptics, measuring 46 inches, are used in the rear. These springs are made from heat-treated steel.

The front axle is an I-beam drop forging with removable bronze bushings in the steering knuckles and ball bearings in the wheels.

A worm and worm gear adjustable steering gear with 16-inch walnut wheel is used with the spark and throttle levers mounted under the wheel. There is also an accelerator pedal.

Instruments on Cowl Board

The dimming switch for the headlights, the ignition switch and ammeter are mounted on the cowl board. The upholstery is tufted and it is stated that liberal leg room is afforded. There is a large deck at the rear for carrying baggage. The body is finished in royal blue and metal parts are standard black with nickel trimming.

While this new company is an independent concern it is closely allied with the Chevrolet Motor Co., inasmuch as all stock holders of the Monroe company are also stockholders of the Chevrolet company.

The Monroe company was organized at Flint, Mich., Aug. 1, 1914, with a capital stock of $250,000, half of which is preferred and half common. The officers of the company are: President, R. S. Monroe; vice-president, W. C. Durant; secretary, Curtis Hathaway; treasurer, Arthur G. Bishop; chief engineer, C. J. Whittacre; consulting engr., John T. Trumbell; purchasing agent, W. C. Rose.

The Improvement of Spring Suspension

(*Continued from page* 988)

torsional effect which is of value when only one of two wheels on the same axle is bumped.

(8) Flexible and elastic vehicle frames; which are often considered undesirable, as they expose bodies and loads to twists and irregular strains and movements.

(9) Seat springs plus upholstering; these are seldom coordinated with the rest of the suspension system.

(10) Spring washers and other anti-vibration devices.

In trying to determine how an equipment composed of some or all of these organs does or does not perform the functions required of it, and how a number of special spring suspensions, to which it will also be necessary to refer in detail, perform similar service, the first thing to be done must of course be to undertake an analysis of the movements to which a vehicle is subject on the road under a number of different representative conditions. In this analysis not only one kind of vehicle must be considered but as many as show essentially different effects, and it is evident that the movement of the body, the load, the running gear must be determined separately and in relation to each other, in so far as possible, and also in relation to the road level and to inequalities in this level, both humps and hollows.

Ward coupé with five-passenger body which sells for $2,100

Ward Has New Coupé and Delivery

Coupé Has Five Passenger Body—Delivery Wagon Sells for $875—750-Pound Body

THE Ward Motor Vehicle Co., New York City, manufacturer of electric trucks, has entered the pleasure-car field by making a five-passenger electric coupé for 1915. This car is complete in every detail and sells for $2,100. In addition a 750-pound delivery wagon is announced for $875. Standard parts are used throughout this car, and it will travel 35 to 45 miles per charge. The other commercial vehicles will be continued practically without change.

The most striking feature of the new coupé is the grouping of all the battery cells in a single compartment at the front of the car. This is covered by a hood, hinged at the rear, which is artistically shaped, its curves blending with those of the body.

Comfort has been aimed at in the design of this machine by adopting a 96-inch wheelbase, large pneumatic tires and coach springs 64 inches long. The upholstery is deep and roomy.

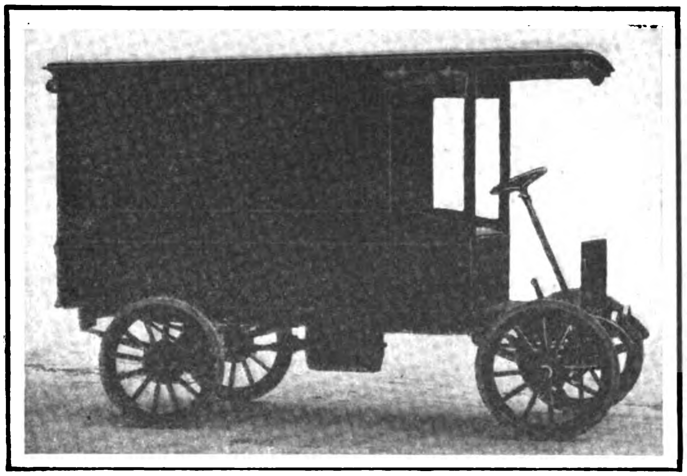
Three passengers are accommodated on the broad rear seat while two more are provided for on individual swivel seats in front. This allows the passenger sitting next to the driver to face forward, or to the rear, as desired.

The interior is upholstered in blue broadcloth to match the body finish. The curtains are of blue silk. The interior equipment includes a silver-mounted flower vase, toilet case watch, memorandum book, and perfume bottles.

Drive on Left

The car is driven from the left side, the horizontal controller being operated with the left hand. There is an electric bell or horn button conveniently placed in the end of the handle. The steering handle, just above the controller lever, is worked with the right hand. There are two sets of expanding foot brakes, either set can be applied and either is sufficiently powerful for perfect control although both can be used if desired.

The master switch is in front of the operator and immediately below the windshield. Three sets of electric light but-



Ward Special light delivery wagon which retails for $875

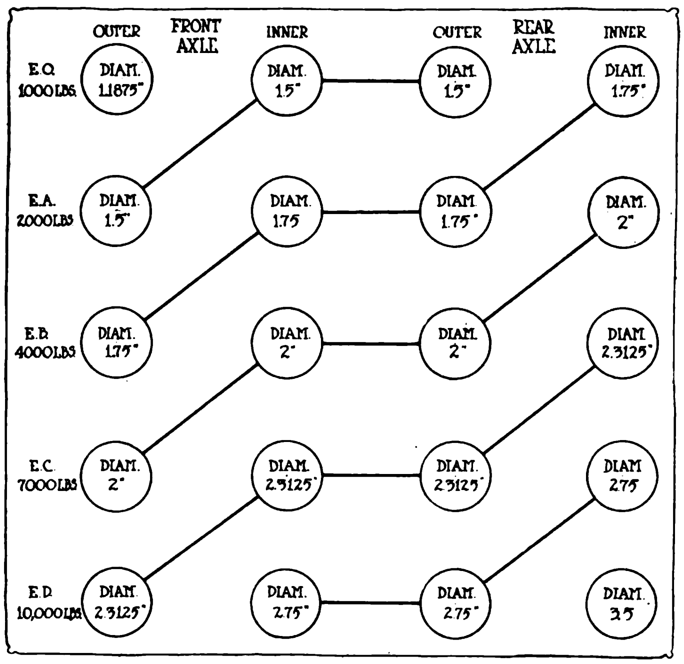


Diagram showing relation between bearings sizes used on five different Ward models. The lines connecting the different circles show the bearings of one size. There are only seven sizes in all

tons arranged on the left just beyond the steering handle, control the lights including a rear lamp and reading lamps.

The battery is a lead cell type made by the company. It has 40 cells of 15 plates each. This gives a mileage radius of from 60 to 100 miles depending on road conditions. The speed varies from 17 to 20 miles per hour. Five forward speeds are provided and there are two reverse.

Power is produced by a 3.5-horsepower General Electric series-parallel motor located amidships. The drive is transmitted through a single pair of bevel gears to a floating axle of Timken make. The front axle is also made by Timken. The springs are alloy steel, heat-treated and 64 inches in length. Wood wheels of the artillery type are fitted and the tires are 34 by 4.5 inches all around. Demountable rims and Brown puncture-proof inner tubes are used.

The regular equipment includes seven lamps, two side lamps, two reading lamps, two standing lamps and one rear lamp, an electric bell or horn; speedometer; locks for doors and control box, hydrometer, thermometer, pump, complete kit of tools and jack.

Ward Special Costs $20 a Month

The Ward Special, which is the name of the delivery car, has been brought out especially to compete with horse-drawn wagons of this type. The Ward company claims that this machine may be stored, washed and charged for $20 per month while a horse and wagon will cost $30.

The driver sits on the left side and steers through a wheel. The control levers are all within easy reach and controller switches are accessibly located under the driver's feet.

A Westinghouse motor is used. It is suspended from the center of the chassis and connects with the rear axle through two universals. Timken axles are fitted both front and rear. From 35 to 45 miles can be obtained from a single charge and the speed varies from 10 to 12 miles per hour.

Wooden wheels and 32 by 2.5-inch solid tires are equipped all around. A single set of expanding brakes act on the rear wheel drums.

The standard finish is a Brewster green body, light green belt panel, and running gear of the same color. The equipment includes storm curtain, lamps, bell, thermometer, plug, cable, hydrometer, and complete kit of tools.

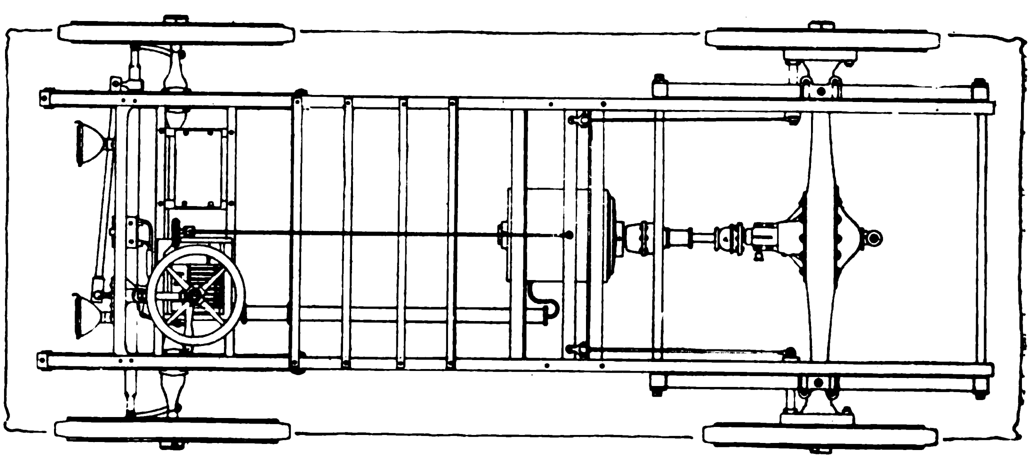
On the five other models there have been no changes of note except in the capacity ratings which are now as follows, the respective prices also being given: 1,000 pounds, $1,250; 2,000 pounds $1,500; 4,000 pounds, $1,900; 7,000 pounds, $2,-450; 10,000 pounds, $2,950.

Wheel Parts Standardized

An interesting feature which is a step towards standardization is noted in the dimensions of wheels, tires, and wheel bearings on these five models. The sizes of wheels and tires progress from the smallest to the largest model so that the total number of sizes is reduced to six instead of having ten as would otherwise be necessary. The rear wheel of one truck is used as the front wheel of the next one and the rear wheel of this truck is used as the front wheel of the following larger size, etc.

This principle is further illustrated in the accompanying figure which shows the bearing sizes for the different models. First looking at the inner bearing on the front wheel spindle of the 1,000-pound truck it will be noted that this becomes the outer bearing on the front axle of the 2,000-pound truck. Likewise, the same diameter of bearing is used for the outer bearing on the rear axle of the 1,000-pound truck. This results in seven bearing sizes instead of twenty.

This scheme of construction not only saves in first cost but where a man has a fleet of trucks of different sizes the stock of repair parts that it is necessary for him to carry is greatly reduced.



Chassis plan of Ward Special, showing motor mounted in the center

Detroit S. A. E. Compares Eight with Six

Attendance of Many Chief Engineers Indicates Intense Interest in Subject—Weight and Balance Much Discussed

DETROIT, MICH., Nov. 23—A discussion of the eight versus the six-cylinder motor held the attention of the Detroit Section of the Society of Automobile Engineers at its meeting on Nov. 20. The attendance and the number of chief engineers present indicates that there is no question but that this is at present the leading topic of design in the automobile industry at the moment.

Opening the discussion was a review by T. P. Chase, chief engineer of the King Motor Car Co., of the considerations which led his company to adopt the eight-cylinder motor instead of the six-cylinder type for coming year. Beside the increase in torque over the four-cylinder design, and the high-speed possibilities of the eight, the King company has been able to place the new motor in the present chassis and under the present sized hood.

Comparison of Weights

A change to a six-cylinder design of the same power as its present motor would have necessitated either a cramping of the body room or the lengthening of the wheelbase. A 90-degree V-type motor is to be used and it is to have practically the same piston displacement as the present model.

Mr. Chase made some interesting comparisons as to the approximate weights of the various parts in the two motors. In the new motor, the cylinders are cast in two blocks, of four cylinders each, and from the rough castings it is estimated that these two blocks, together, weigh about 28 pounds more than the single block of the present four-cylinder motor. Other comparisons indicate that the eight connecting-rods weigh but little more than the four old rods; crankshaft bearings are of practically the same size, and therefore, of the same weight; and the flywheel, of course, does not have to be as heavy as on the four, due to the increased number of explosions per revolution. In these two motors, of practically the same piston displacement, it is estimated by Mr. Chase that the eight-cylinder job, complete, will not weigh over 35 pounds more than the present four-cylinder motor.

It is possible to make the connecting-rods each considerably lighter than those of the four-cylinder motor, due to the fact that they have to withstand a smaller total pressure, since the areas of the pistons are less. The same applies to the bearings.

In relation to sizes and weights, Wm. B. Stout, chief engineer of the Scripps-Booth Co., stated the law governing areas and volumes. By this law areas increase or decrease by two dimensions, while volumes may vary in three dimensions. If a mass is made on-half the size of another mass, the surface will be one-fourth as great as the latter, and the weight one-eighth as great. Mr. Stout cited the aeroplane as an example of this. With a machine half the size of another the wing area per unit of weight will be twice as great.

Considering the weight and area relations of high-speed motor-car engines, the above law also holds within the limitations of construction. These limitations mean that in foundry practice a piston wall can be cast only just so thin and, therefore, it is often impossible to make the parts as light as would be theoretically possible. If a piston for one motor was of the correct weight, the theory would show that another piston of half the dimensions would have one-fourth the working area, and one-eighth the volume.

Light Reciprocating Parts

Even with the practical limitations of construction, a motor with the same stroke as another but with half the bore will give better high-speed results than the other, due to the greatly reduced weight of the reciprocating parts, and the resulting decrease in vibration, together with the greater possibilities in revolutions per minute. The newer 3 by 6-inch high-speed motors certainly show a decided improvement over the older 6 by 6-inch square motors. Mr. Stout stated that passenger comfort depended not so much upon the impulses per revolution as upon the number of revolutions per mile. Since the eight-cylinder motor will be primarily a high-speed motor, and also give more explosions per revolution than the four or six, the increase in the impulses per mile will be very marked.

In Favor of Six

For the six-cylinder side, the case was presented by J. G. Vincent, chief engineer of the Packard, Allen Loomis, also of the Packard, and S. I. Fekete of the Hudson. Mr. Loomis drew numerous diagrams upon the blackboard in explanation of the balance of the inertia forces. He showed that due to the angularity of the connecting-rod the inertia curve is not a true harmonic motion, and for this reason the inertia forces do not exactly balance in the four-cylinder motor when the cranks are in the horizontal and vertical planes. With the cranks in the vertical plane the unbalanced portions tend to lift the four-cylinder motor, and when in the horizontal plane there is a downward thrust. These unbalanced forces tend to cause the four-cylinder motor to vibrate up and down.

Questions of Balance

The new eight-cylinder motors have the cylinders inclined to each other at 90 degrees, or in other words, their center lines are inclined 45 degrees from the vertical plane through the crankshaft. The unbalanced inertia forces in each block of four cylinders are, of course, the same as in the case of a four-cylinder motor, and act along the center lines of the cylinder. Since these center lines lie in planes inclined 45 degrees from the vertical, the inertia forces may be resolved into vertical and horizontal components. Because of the relations between the piston movements in the two sides of the motor, the vertical components of these forces cancel each other, and there is no tendency for the motor to vibrate up and down. The horizontal forces, however, add to each other, and during part of a revolution their direction is to one side of the motor, while later it is to the other side. These horizontal forces, therefore, mean that there is a tendency for the motor to vibrate sideways.

Vibration Tendencies

In the six-cylinder motor a plotting of the inertia forces shows that the resulting reaction on the engine base is equal to zero. There is, therefore, no tendency to vibrate in the six-cylinder motor, due to unbalanced inertia forces.

Another solution, showing the tendency of four and eight-cylinder motors to vibrate, was presented by Mr. Fekete. This speaker considered the center of gravity of the total system of pistons and connecting-rods. He stated, that due to the angularity of the connecting-rods the center of gravity in a four-cylinder motor would vary up and down as much as 5-8 of an inch. Plotting this movement for the eight-cylinder motor the variations for the two sets of cylinders would, in some cases, add to each other so that the total variation might easily be as great, in some cases, as 3-4 inch. In a properly designed six-cylinder motor, Mr. Fekete said that the center of gravity of the piston and connecting-rod systems did not move.

Preventing Crankshaft Whipping

Although the theoretical discussion showed the inertia forces in the six-cylinder motor to be in perfect balance, the point was brought up as to the difficulties in six-cylinder design in preventing the whipping of the long crankshaft. In the eight-cylinder V-motor the crankshaft need be no longer than in a four-cylinder motor, and therefore, the vibration and other difficulties arising from the springing and whipping of the crankshaft may be more easily overcome than in the case of the six.

Speaking of the relation of the ignition problems to the eight-cylinder engine, A. de Maringh, of the Mea company, thought that battery ignition would not be suitable for these new type engines, due to the great speed which would be required of the coil. He believed that a magneto would be required for the best service.

The New Fuel

ALTHOUGH the new fuel may be manufactured in quantities at 2 cents per gallon as reported and sold in quantities at 6 cents per gallon; and although it has demonstrated its practical value in a 1000-mile speedway test, it must not be assumed that it has taken a place side by side with gasoline, with the possibility of ousting the older fuel from the field in a few years. The promoters of the fuel may have no such thought in mind, rather they apparently have a new fuel which offers particularly attractive manufacturing and merchandising qualities, and its entry into the field cannot be looked upon with anything else but a spirit of welcome, as any new fuel that will tend towards lower existing prices will be gladly received.

The fuel will face greatest competition when it comes to the question of manufacture for general distribution and then will follow the greater problem of national distribution. The distribution of any motor fuel must be as general as that of the sale of sugar or any other household staple. Gasoline is really becoming more so by the wide extension of the curb-side station, which during the past year was so extended as to make it unprofitable for many garages to sell it. The new fuel has to meet these conditions.

Merchandising motor fuels is one of the expensive factors in connection with them. For several years we have seen our big refineries buy the crude, pump it a thousand miles or more to the refinery, refine it, load it into railroad tank wagons and ship it to substations, and there load it into tank motors and deliver to garages and private users for 10 cents per gallon or under. While this was being done many garages were selling it for 20 cents and some for 25 cents per gallon, yet these garages had nothing to do but install a storage tank with pump and pump it into the tank of the automobile. Look on the one hand what the manufacturers did for 10 cents and then what the middle man did for the same amount.

Viewed in the light of merchandising conditions the new fuel has its battles to win. It is sincerely hoped that it may develop into a fuel forming a worthy rival of gasoline, and further that if it attains such prominence, that, then, may come some economies in merchandising which will make it possible for the car owner to profit by reduced cost of manufacture rather than losing all of such advantages due to the merchandising of it through a middle man at an unreasonable profit.

Rational Fire Regulations

THE recent activity of the fire-marshal department in New York State, in which a new code of regulations governing the construction of new garages and modifications to be made in old ones was promulgated, suggests how essential it is for automobile manufacturers and dealers to take due recognition of the abuses that are certain to invade any industry and to take measures to correct these before too great activity is launched from other sources.

Every new industry has its abuses, and it cannot be denied that there are many garages in New York State and in nearly every other state in the Union that violate all rational regulations. On the other hand the majority of the new garages are exemplary structures, practically on a par with the moving picture theatre in obedience to fire regulations. With the revamped livery stable as an example of the fire trap in the garage field, it at once becomes imperative on those with modern buildings to take up the burden of getting a higher standard in the dangerous buildings.

It cannot be gainsaid that there are dangers connected with the general use and storage of gasoline in a garage or repairshop, but if we hedge the storing and handling of the gasoline around with good safety precautions there is not any reason why we should go to the opposite extreme and introduce unnecessary legislation, once we have really eliminated the danger factor of the garage.

It is absurd to draft any laws prohibiting the use of an open torch in a repair shop, and requiring that the torch can only be used in a separate room with a door opening only to the outer air. It is generally equally absurd to require the same regulations governing heating boilers, etc. What is needed is sane legislation.

To Revise Fire Regulations for Garages

New York Trade Association Shows Injustice of Enforcing Present Rules—Another Hearing Before State Marshal December 9 —Saxon Brings Out Five-Passenger Six

ALBANY, N. Y., Nov. 18—The regulations governing changes in structure of garages and repair-shops recently promulgated through the state of New York by Thomas J. Ahearn, state fire marshal, and which regulations were to take effect December 1, have been temporarily held up, due to a conference in the state capitol today at which the Automobile Trade Assn. of New York showed why the present regulations are unjust, inconsistent and in many cases would work very serious injury to existing garages in the state. As a result of today's conference the existing regulations will not go into effect December 1 and it is probable that they will not be enforced at all in their present manner.

Another Hearing December 9

On December 9 there will be another hearing before the state marshal at the capitol here when the officers of the State Dealers' Assn. will meet with the state fire marshal to revise the present code. It is expected that in this revision a great many of the articles will be changed and that the enforcement will not follow until requisite time. In the meantime the state marshal is notifying all of his deputies throughout the state that the code as promulgated will not be enforced December 9 and matters will remain as they are until a revision is accomplished.

At today's hearing president R. H. Johnston, of New York City, and head of the State Dealers' Assn., read letters from Rochester dealers showing how the Rochester fire marshal had notified them that their garages were violating the new code and that alterations must be made before December 1. Practically every garage in Rochester had received notification covering improvements on the ceilings of the garages, requiring metal lath and three-quarters inch of plaster; also notifying them that the repair-shop must be separated by a fireproof wall with automatic fire doors from the garage proper; also that staircases and elevators must be enclosed in fireproof partitions with automatic fire doors; also that metal window frames and sashes with wire glass must be changed, etc., etc.

It was shown that one dealer would have to make an expenditure of $6,000 on his garage in order to conform with the new requirements, and that these changes could not be made inside of 8 weeks, although only 2 weeks were given in which the work was to be done and if not completed at the end of that time action would be taken towards closing the garage according to the regulations.

This danger has now been overcome and the probabilities are that the final draft of garage regulations will be entirely rational and not work a foolish hardship on any garageman with the exception, perhaps, of those who have located in one-time livery stables which have not been brought up to rational fireproofing standards.

Many Unfeasible Rules

Today's hearing demonstrated conclusively that there are many unfeasible rules in the existing regulations. One is that a torch cannot be used in a repair-shop, the idea of the regulations being that there would have to be a separate fireproof room in one corner of the repair-shop. The torch, forge, etc. would have to be used in this fireproof room and this room would not have a door into the repair-shop but only one leading into the outer air. It was shown that this was impossible in many existing modern garages built in entire accordance with the existing fire laws previous to the recent code which the state fire marshal had circulated. If there is to be a fire door between the repair-shop and the garage, and if gasoline is not permitted in the repair-shop, then there is no reason why the open torch or the forge should not be permitted without restrictions in the repair-shop.

Then if the revision takes place it is certain that there will be a new classification of garages instead of the promulgated one.

Charles Thaddeus Terry in arguing the case for the New York dealers, drew attention to the general lack of feasibility existing throughout the new draft. He attacked the basis of garage classification on the ground that it was unfair and irrational. He cited one case where an existing garage has a cement floor 2 3-4 inches thick but according to the promulgated regulations this should be 3 inches thick and that it would be impossible to lay an additional 1-4 inch and have a satisfactory floor.

The regulation requiring that heating boilers be located in a room with an entrance only leading to the outside air was shown to be impracticable in many existing fireproof garages.

The New York State Dealers' Assn. is going to get from all of its dealers an expression of opinion on the various garage questions and will go to the next hearing on December 9 in possession of all this information so that the outcome should be a code of garage and repair-shop regulations that are sane and enforceable.

Saxon Brings Out 5-Passenger Streamline Six

DETROIT, MICH., Nov. 20—The Saxon Motor Co. has had a new car on the road in the vicinity of the city for the past 6 months which will be shown at the New York show. It is a six-cylinder type of five-passenger body design, with stream lines and sloping hood.

In bringing out this new model, the production of the small four-cylinder roadster at $395 will not in any way be curtailed. In fact, the success which this car has attained since the concern was started about a year ago has prompted the arranging for greatly increased output of the four for the coming year.

Present factory facilities have become inadequate and plans have been completed for utilizing parts of factories near the present plants on Bellevue avenue. The overflow quarters are on Beaufait avenue, and they give to the Saxon company triple the factory space it formerly occupied.

General Electric To Make Starters

NEW YORK CITY, Nov. 21—A new electric starter is about to be placed on the market by the General Electric Co. of Schenectady, N. Y., Lynn, Mass., Windsor, Conn., and Fort Wayne, Ind. The first effort of this giant concern will be the production of a starter for Ford cars to market at $87.50. It will be a single-unit design made under the trade name G. E.

The selling end of the business will be handled through the A. J. Picard company of this city which has signed a 3-year contract. This concern has been taking care of the Gray and Davis interests in New York and has been closely in touch with the industry, through its president A. J. Picard, for several years.

Welfare Men Want Truck Drivers Examined

YORK, PA., Nov. 21—At the second annual conference of the Industrial Welfare and Efficiency Conference held in this city for 3 days last week and at which the welfare of workmen and workwomen in factories was the subject of much discussion, the adoption of an act requiring all drivers of motor vehicles to take an examination before an examining board was favored by several of the delegates. The examining board would issue a certificate and it was hoped by this means that accidents would be reduced.

SYRACUSE, N. Y., Nov. 23—The Brown Co., of Syracuse, N. Y., announces that it has purchased the rights, plans and good will of the Lewis-Sanford Pump Works, Boston, Mass. This concern has manufactured several types of pumps, the latest of the line being the one-cylinder pump of original ideas and adaptable to Ford and several other makes of cars.

France Buys 900 More Trucks

600 of 2-Ton and 300 of 5-Ton Type Bring Total U. S. Sales to France to 2,640

NEW YORK CITY, Nov. 23—The French government which some 6 weeks ago purchased 1,740 motor trucks from four American companies, namely, White, Packard, Pierce-Arrow, and Kelly-Springfield, made another purchase last week from White and Pierce-Arrow. Both orders were practically a duplicate of the previous ones, the White order being for 600 of their 2-ton models. The Pierce order is for 300 of the 5-ton trucks. This last order makes a grand total of 2,640 American trucks sold to date to the French government as the result of the present war.

Word comes from Detroit that the Standard Motor Truck Co., that city, has received an order for 100 trucks, some 3-tons and other 5-tons. These have been sold to the British government.

Special Work for Big English Firms

LONDON, Nov. 10—There is little if any change in regard to the condition of touring car manufacturers in England, many of them being out of action indefinitely, to use a military phrase. Fortunately some of the larger concerns that were well equipped with automatic machinery have been able to undertake the production of special work for the war department, which will continue until the end of the war.

Government Buys Chassis

The completed chassis which the majority of the English companies had on hand when the war broke out have been disposed of to the government, many being fitted with armored bodies for scouting work. The Red Cross has absorbed a great many of these. As an indication of government orders there is the case of the Vulcan Motor Co., which has obtained an order for vehicles and parts to the amount of $1,000,000 during the past month, which will keep the factories busy for some time. The war business in the commercial vehicle end has greatly helped conditions and the leading factories now operating for the government are producing approximately seventy chassis per week. Firms not engaged on orders for the British government are working on others for the Belgians and Russians. Only last week the Austin Motor Co., secured a Russian order amounting to $1,250,000, with an additional order for parts valued at $250,000.

This order called for forty-eight armored cars, each carrying two machine guns and five men and with a maximum speed of 40 miles per hour; eighteen automobile work shops equipped with lathes, drills, etc., sixteen tank wagons for transporting gasoline; eight spare-parts wagons equipped as traveling stores; 128 ambulances for twelve stretchers each; and 100 transport wagons of the 3-ton type. In addition there was a large equipment of accessories such as jacks, lighting sets, extra tires, spare parts, etc.

There is much enterprise being shown here by several American makers of trucks. The Peerless company, which had some trucks accompanying the Canadian contingent is here demonstrating. The Jeffery quad or four-wheel-drive, is making an impression on the war authorities, the Standard of Detroit is being demonstrated, as is the Fremont-Mais, as well as several others. It was reported here that the Woolesley company, one of the largest makers of gasoline trucks in England, has secured the agency for the full line of Baker electrics in this country.

Shortage of Horses

The shortage of horses is becoming a critical factor in England, and already the government has special buying agents through all the South American countries. This condition is bound to have an effect on the motor vehicle industry in the near future.

Conjecture has it in and around the war office in London that should the war be prolonged over another year or longer, there will not be much slackening in the demand for commercial vehicles for field service. Britain's army will be much larger next spring, and at present the Russian army is being handicapped by lack of trucks. Lord Kitchener is at present training an army of 1,000,000 men in different parts of the British Isles. These are to take the field in the spring and their presence in the war zone will call for a great increase in motor equipment. It has just been reported that the Australian government has voted $1,000,000 for motor equipment to accompany its expeditionary force which is now being prepared.

Many other reports are current in London regarding truck sales, one being that Whitings, Ltd., has secured an order from the Russian government for fifty American Federal trucks.

The present winter has already greatly hampered the use of trucks in Russia, Eastern Prussia and Austria. Non-skid tires are receiving much attention, and now many of the armored cars are being fitted with a tire known as the K.T., which, instead of being a continuous band of rubber, is made up of rubber studs placed very closely together. Another device extensively used is the Parsons non-skid chain as well as the Never-Skid device. It has recently been learned that the German government in June had placed a very large order with the English company for Parsons chains, the order to be delivered on telegraph demands. These demands came at the time the war broke out and deliveries were not made.

Many Steam Wagons

An interesting aspect of motor transportation in the war is the great number of steam wagons collected from users throughout England. These wagons were largely used in the milling industry and are giving a good account of themselves in the hauling of heavy guns in the war zone. They have been fitted with specially wide tires, making it possible for them to be used in soft fields.

Metzger Sues United States Motor Directors

NEW YORK CITY, Nov. 20—Emanuel Metzger, a minority stockholder in the old United States Motor Co., which was succeeded by the present Maxwell Motor Co., has filed a suit in the Supreme Court for New York county, asking that the directors of the old company account for assets which he alleges were wasted during the months prior to the receivership. Metzger attempted to intervene in the receivership

Automobile Securities Quotations

NEW YORK CITY, Nov. 24—During the past week there was a market for automobile securities on the curb, but not a very active one. The following quotations are those which a prominent brokerage house finds to obtain in private sales and are not to be taken as official. However, they will serve as a guide until the re-opening of the Stock Exchange.

proceedings in the federal court in New York a year or so ago but was ruled out by the court.

As individual defendants he names James C. Brady, Benjamin Briscoe, Frank Briscoe, Richard Irvin, Herbert Lloyd, Johnathan D. Maxwell, Eugene Meyer, Jr., Edgar J. Meyer, Ora J. Mulford, Henry W. Nuckols, Richard A. Robertson, Kenneth B. Schley, Charles G. Stoddard, James W. Stoddard, Carl Tucker and the company itself.

Another echo of the receivership was heard in the United States district court in New York last week when Harold A. and John C. Howard, trustees of the estate of Sarah J. Howard, secured permission to sue the old Maxwell-Briscoe Motor Co. They demand the balance on a lease on the company's Chicago branch, the lease running until 1929 and payments having ceased in the summer of 1913.

The assets of the United States Motor Co. were sold by the receivers with the permission of the court and were in turn sold to the present Maxwell corporation. The receivers have not yet been discharged and the United States Motor Corp. and its subsidiaries still exist in form at least. Under a ruling of the court, claimants were required to appear before a certain date or be stopped from collecting, and it was this ruling which had to be modified before the Howards could sue on their lease. Should they recover they may collect under an arrangement made by the court when the Maxwell Motor Co. bought the assets.

Haynes Asks Retrial of Agent Suit

KOKOMO, IND., Nov. 21—The Haynes Automobile Co. has asked for a retrial of the suit brought against it by Benjamin H. Goodman, Omaha, Neb., whose dealership contract, signed at the factory in the afternoon, was rescinded in favor of one given in the forenoon in Omaha to C. F. Louk. The Goodman contract was given by sales manager Richard Bacon and the Louk contract by S. H. How, a field representative of the Haynes company. After long litigation and an appeal from the United States district court to the Court of Appeals, Goodman recently secured a verdict of $3,250.

Manufacturers state that such a condition could not now arise because of a contract clause which requires the approval of some high factory official before any contract becomes binding. But in 1909 this apparently was not the case with the Haynes company.

Goodman's story is that during the afternoon of September 1, 1909, he contracted at the factory in Kokomo for twenty-five Haynes cars and gave two checks totaling $1,250 as deposit. At 11 o'clock that morning the traveling representative in Omaha had signed up Louk; both contracts were for an exclusive agency. As soon as the Haynes company discovered the duplication it returned Goodman's deposit September 8, with an explanation that the Louk contract, made several hours earlier, must stand.

His deposit checks had been cashed by the company, however, and the return was by a Haynes check, which Goodman also cashed. When he went to the factory again to insist that the contract be carried out he tendered $1,250 in cash as a deposit. The offer was declined.

He sued for $25,000, in the United States district court for Indiana and Haynes won. On appeal Goodman secured a new trial; on the new trial a jury gave him $3,250, November 12, 1914. The reasons given by Haynes in its motion for a new trial are that the verdict is not substained by sufficient evidence, is contrary to law, is contrary to evidence and is too large.

Piel Charges Infringement of Long Patent

NEW YORK CITY, Nov. 23—Gottfried Piel and the G. Piel Co. filed suit yesterday in the United States district court against the Stewart Warner Speedometer Corp., charging infringement of the Long hand horn patent, No. 1,090,080. It is charged that the Stewart Warning Signal, recently brought out, infringes the Long patent in its diaphragm and adjustable wear piece. The suit is directed against the manufacturing company, a Virginia corporation, and the New York branch, a New York corporation.

C. of C. Special Meeting December 3

NEW YORK CITY, Nov. 23—A special meeting of all the members of the National Automobile Chamber of Commerce has been called by President Clifton for Thursday, December 3, at 11 a. m., at which time the attention of the entire chamber will be drawn to the present litigation of the Kardo company on floating axle construction and other patents. It is expected that the national chamber may consider the advisability of defending suits brought against its members by the Kardo company.

Prompt Shipment of Crude Rubber

NEW YORK CITY, Nov. 20—Arrangements are being made for operation of steamers, carrying the Holland flag, from Sumatra and Java direct to the United States, in order to enable consumers of crude rubber in this country to get their supplies of plantation grades more promptly. According to plans now under consideration the first vessel will sail from the Far East on December 20.

The cruiser Emden, which was recently sunk after a career in which she destroyed many merchant vessels, was the cause of some worry to the rubber trade of the United States, and there was general relief at the news of the Emden's destruction. That vessel, it is said, probably cost the rubber industry in America $1,000,000, and had she been allowed to continue to roam the Indian Ocean indefinitely she would have cost the American industry still more.

Before she was sunk, the vessel destroyed two dozen merchant ships, carrying 3,900 tons of crude rubber.

Overland Car Shipments Increase 4,194

NEW YORK CITY, Nov. 23—The Willys-Overland Co., Toledo, O., shipped 15,207 cars up to November 6, as against 11,013 for the same period in 1913. The shipment for the first 6 days of November was 1,135, as against 803 last year. The total shipment of 1914 cars was 45,003. The output for 1915 will be 75,000.

Chicago Stock Exchange Resumes Trading

CHICAGO, ILL., Nov. 23—The Chicago Stock Exchange opened its doors today and trading resumed where it stopped July 30, when with other trading centers the Exchange closed because of the European war.

That the stock exchange in New York City is quite certain to reopen for limited business before the end of the month, was the substance of the assurances received from responsible banking and brokerage authorities. On Nov. 24, the Governors of the Stock Exchange will meet for the purpose of deciding the question of resuming business in bonds.

Market Reports for the Week

Changes in the market reports this week were few. These few were increases, occurring in the copper, tin and cottonseed oil markets. Electrolytic and Lake coppers saw a slight gain for the week with business quiet, although a firmer tone prevailed in sympathy with the further rise at London. Tin went up $1.63 per 100 pounds, in sympathy with the further sharp rise at London due partially to the unfavorable reports in the Far East affecting the safe transportation of tin from the Straits to Europe. Cottonseed oil rose $0.18 per barrel. However, the tone is unsettled and the consuming demand not what it was a week ago, being then very strong. The local market for crude rubber lacked new features of importance last week. Inquiries continue light, consumers being disposed to go slowly in the matter of replenishing supplies pending new developments in the situation.

Lead rose $0.20 per 100 pounds, closing at $3.90. This product was quiet but firm at the closing. The rest of the markets remained at the same prices quoted last week. In the metals markets, antimony was quiet at $0.13 1-2, the other markets remaining steady. All of the oils and lubricants continued steady. A moderate demand was reported for petroleum. Linseed oil was firm with trading more active.

INDIANAPOLIS, IND., Nov. 20—To demonstrate that a new motor fuel which it is claimed can be manufactured for 2 cents per gallon, and marketed at 6 cents per gallon in large quantities, is a practical fuel for motor car use, an official 1,000-mile test was made on the speedway here yesterday and today with the Marmon 41 touring car, covering 500 miles each day.

The new fuel was employed throughout the test in which the 1,000 miles were covered at an average of 50.2 miles per hour. Throughout the test only one apparently serious trouble was encountered at the end of the first 100 miles when it was discovered that the fuel was apparently frozen in the vacuum tank where it enters the carbureter. It was necessary to clean the pipe out, a 40-minute stop being required. This trouble was explained as being due to failure to strain the fuel before putting it in the car. With this single exception the fuel gave apparently satisfactory results although the consumption was rather high, averaging 7.42 miles per gallon. The weather was not satisfactory to a test of this nature, being very cold, the temperature during the first day ranging from 10 to 20 degrees Fahr. and on the second day being as low as 6 degrees at the start but rising to 25 when the trials were finished late in the afternoon.

The new fuel used showed a hydrometer reading of 55 Baumé as compared with 58 Baumé for gasoline. This 55 reading was at 40 degrees Fahr. and at 28 degrees Fahr. the reading was 53 Baumé. This fuel, as described in THE AUTOMOBILE, July 9, is made from a number of secret chemicals with water and naphthalene also used. Naphthalene is a substance from which moth balls are made and it is because of this that this fuel has been so closely associated with moth balls in the minds of many people. The fuel is said to have a moth ball odor.

The test showed that speeds, that compared favorably with those made by using gasoline, were obtained. The Marmon 41 used in the trials was the same car that a week ago averaged 62.89 miles in 1 hour with top and windshield up and carrying five passengers. In the new fuel test the car carried but the driver and mechanic and had the windshield up but the top down. With this equipment it averaged 55.25 miles per hour during the last 100 miles of the test. Its other average for 100 mile periods ranged between 49.45 and 54.80, the average for the entire distance being 50.2.

After the test was over the motor was dismantled in order to note the carbon deposits that had collected. In this examination the cylinders were taken off and the valves removed. The official report made by F. E. Edwards, technical representative of the contest board of A. A. A., states that "the metal parts of the engine are remarkably clean, showing very little more deposits than were found in this same engine at the completion of its 1-hour trial on November 12. No deterioration of metal parts due to chemical action was to be observed with the eye."

The fastest lap in the 2-day trial was second to the last, which averaged 62.85 miles per hour, a speed practically equivalent to that which the car averaged with gasoline in its hour test on November 12.

When the total lost time of 1 hour and 56 minutes is taken out, the average speed is brought up to 55.95 miles per hour.

The trials were timed by a new electric timer, the invention of Chester Ricker, the speedway engineer.

INDIANAPOLIS, IND., Nov. 23—Plans for a trip to the Panama-Pacific exposition to be held in California next year have been outlined to the Hoosier Motor Club. Division No. 1 would leave Indianapolis June 1 and require about 60 days for the trip. Division No. 2 would leave about July 1 and would require 30 days. The third division which would be a special train, would leave July 26.

Twenty-One Entries for Corona Road Race

Practice Starts for 301-Mile Contest

CORONA, CAL., Nov. 19—Twenty-one entries have been received for the Corona road race to take place on the Grand boulevard, Thanksgiving Day.

The purse is $12,000 and the $5,000 Flagler trophy.

The length of the course is 2.76895 miles. The race is 109 laps or a total of 301.81 miles.

Practice started on the course November 17.

Nineteen More Exhibitors for Big Shows

NEW YORK CITY, Nov. 23—Seven makers of electric passenger cars, two makers of gasoline passenger pleasure cars, and ten accessory exhibitors have been added to the already long list for the national automobile shows in New York and Chicago. Following are the electrics: American Electric Car Co., Saginaw, Mich.; Anderson Electric Car Co., Detroit, Mich.; Baker Motor Vehicle Co., Cleveland, O.; Ohio Electric Car Co., Toledo, O.; Rauch & Lang Carriage Co., Cleveland, O.; Waverley Co., Indianapolis, Ind., and Woods Motor Vehicle Co., Chicago, Ill. All of these makers will exhibit at both shows, except the American Electric Car Co., and the Woods Motor Vehicle Co., which will be only at the Chicago exhibition.

The added gasoline car makers are: Chevrolet Motor Co., New York City, and Trumbull Motor Car Co., Bridgeport, Conn.

The ten new accessory exhibitors are as follows: Chicago and New York Charter Single Sleeve Motor Co., Chicago, Ill.; Gray Bros. & Co., Chicago, Ill.; Lipman Air Appliance Co., Beloit, Wis.; Mathisen Spring Cushion Wheel Co., Chicago, Ill.; A. J. Picard & Co., New York City; Positive Supply Co., Davenport, Ia.; Wm. Shakespeare, Jr., Co., Kalamazoo, Mich. At New York only will be: Eclipse Machine Co., Elmira, N. Y.; W. S. Sheppard, Newark, N. J.; K. G. Welding & Cutting Co., New York City.

Cut Down Space at Quaker Show

PHILADELPHIA, PA., Nov. 21—Owing to inability to secure adequate quarters to accommodate all the would-be exhibitors at the forthcoming automobile show of the Philadelphia Automobile Trade Assn., that organization has been compelled to adopt a plan restricting the amount of space to be allotted. In order to secure a representation of the greatest number, any member handling but one make of car will be limited to 400 square feet of exhibition space. An additional 200 square feet will be optional to those handling two or more makes.

Drawings for space will take place at a meeting of the Trade Assn. to be held next Tuesday.

Vanderbilt and Grand Prize Course Practically Completed

¶ SAN FRANCISCO, CAL., Nov. 20.—*W. L. Hughson, chairman of the Vanderbilt and Grand Prize racing committee, states that the course on which the big races are to be run in February is practically completed and some fast laps have been made to show the possibilities of the 4-mile lap. The entire course has been changed from a gravel road to an asphalt surface.*

The course is 4 miles around and ranges in width from 40 to 70 feet. There are two right-angle turns and at each of these the road is 70 feet wide. There are two half turns, two gradual curves and one hairpin. The race will be spectacular from almost any point on the course. The grandstand will accommodate 25,000 people.

Dissension in N. Y. State Association

Rochester and Buffalo Clubs May Join Syracuse—Drop Forge Association Formed

POUGHKEEPSIE, N. Y., Nov. 19—There may be formed in New York State an independent organization as an aftermath of the proceedings at the annual convention of the New York State Automobile Assn. which closed here tonight. The convention, which began yesterday, was the scene of a faction fight between the present association organization, headed by President A. J. Deer, Hornell, and the Rochester and Buffalo clubs, which endeavored to prevent Deer being chosen for a fourth term and also attempted to have the by-laws amended. They were steam-rollered in all their moves, and the larger part of the two big club delegations left before the convention ended.

The fight was for and against Deer. The Rochester and Buffalo clubs charge that he is operating *Motordom*, the official organ, as a profit-paying enterprise. Deer replied that, while he owns 398 shares in the publication, he is willing to turn it over to the association as soon as it is free and clear from an indebtedness of $15,000. Deer had secured and voted twenty-three proxies from the smaller clubs of the State, and this proxy question was another source of difference. One of the amendments proposed by Rochester and Buffalo was that a proxy must be held bv a resident member of the club represented. It failed to pass.

So strong has been the opposition of the two big clubs to the conduct of Deer and his organization that they had not paid dues up to the hour the convention opened: at that time Buffalo paid dues for 3,002 members and Rochester for 2,861, thus giving their delegates standing. After having been steam-rollered, however, they stated that there was a strong possibility that Rochester, Buffalo and Syracuse would form an independent organization—Deer termed it a "progressive party"—and ask recognition from the A. A. A. If formed, it would have about 10,000 members and would be about equal in strength to the regular organization. The matter is to be taken up at the next meeting of the respective clubs. Syracuse pulled out about 2 years ago.

Highway Commissioner John N. Carlisle injected an element of surprise when he suggested that there be a reciprocal arrangement between New York, New Jersey, Massachusetts and Connecticut whereby foreign tourists pay a tax of 4 cents a gallon on gasoline for good roads maintenance. Sanitary Supervisor Paul V. Winslow, of Wappingers Falls, suggested that the association co-operate with the State in sanitary work about hotels and other public places.

General Counsel Melvin Bender reported on bills which had been throttled during the year and urged the passage of a wheel tax. The convention named a committee to take up long detours because of closed roads. Leaving half the road passable was urged.

The association now has seventy-five clubs, a gain of thirteen, and 17,516 members, a gain of 2,995.

American Drop Forge Assn. Formed

DETROIT, MICH., Nov. 20—Factory superintendents and shop men from American and Canadian drop forge manufacturing concerns met here yesterday and formally organized the American Drop Forge Assn.

A preliminary meeting was held several weeks ago with this organization in view and the officers then suggested were elected at yesterday's meeting. These officers are: R. R. Ellis, superintendent Detroit Forging Co., Detroit, Mich., president; George Des Autels, manager Anderson Forge & Machine Co., Detroit, Mich., vice-president; A. E. Dibble, manager Frost Gear & Forge Co., Jackson, Mich., secretary; E. B. Horne, superintendent Packard Motor Car Co., Detroit, Mich., treasurer.

An executive committee was then named consisting of the following men: E. Ingalls, Ingalls-Shepard Forging Co., Harvey, Ill.; M. Henry, Henry & Allen, Auburn, N. Y.; C. A. Prochler, Canton, O.; R. Herdegen, Dominion Stamping Co., Walkerville, Ont., and E. B. Horne, of the Packard Motor Car Co., Detroit.

"The object of this organization," said Vice-president Des Autels, "is to bring the factory and shop men in the drop forge industry together. It must not be misconstrued that the manufacturers have organized. As a matter of fact we managers and superintendents have not asked the manufacturers what they thought about the idea and we took steps among ourselves because we found it advisable that we should get better acquainted as to matters concerning the shops. We want to better conditions for the shop men, we desire to discuss our mutual methods and improve them, to get together from time to time at meetings similar to those of the society of automobile engineers, and especially, to promote better efficiency among the men."

History and Progress at E. V. A. A. Session

NEW YORK CITY, Nov. 23—Things which were serious in the early days but which cause smiles now were described by Robert McAllister Lloyd last week at a meeting of the New York section of the Electric Vehicle Assn. of America; he talked on The Influence of the Pioneer Spirit on Electric Vehicle Progress. Lloyd is a consulting engineer and one of the old-timers in the electric vehicle field.

He said the first impulse given the industry was by the battery makers who sought a new market for their products; the second motive was the public craze for the electric when $70,000,000 of capital was put into the industry, only to suffer loss by collapse; then came the "dark ages"; the next impulse was given by the electric light companies which, too, sought an extended market for their current. Pioneering, he said, was over by 1908.

Lozier Company Fights Insolvency Charge

DETROIT, MICH., Nov. 24—*Special Telegram*—U. S. District Judge Tuttle yesterday granted permission to three creditors of the Lozier Motor Co., to amend their petition to the Court to include the charge of bankruptcy because the company is unable to pay its debts.

At a meeting of directors of the company a special committee consisting of J. M. Gilbert and E. D. Stair, of Detroit, and E. P. Earl, New York City, was appointed to confer with Eastern creditors holding claims for about $1,000,000 to further discuss plans for reorganization and legally avoid, if possible, having the company being declared bankrupt on the grounds that the company is unable to pay its debts. The hearing of the creditors has been set by the court for December 1.

Overland's Connecticut Dealers Hold Convention

HARTFORD, CONN., Nov. 23—Thirty sub-agents of the Overland-Connecticut Co., which has all of the state of Connecticut with the exception of Fairfield county, met at the Hartford headquarters Friday for a business convention. Addresses were made by general manager C. W. Hine and sales manager Carney of the Hartford office and by H. B. Harper, factory sales manager, R. L. Lockwood, special factory representative, I. F. Maxson, district factory representative and J. R. Wallace, factory mechanical representative. All the new Overlands were on display in the local salesrooms. Several of the sub-agents drove away with new cars to be used as demonstrators in their respective districts.

A Many-Named New Spark Plug

NEW YORK CITY, Nov. 23—Over 3,800 names for a new spark plug were received by the Emil Grossman Mfg. Co. in its contest for a name for its new plug. R. F. Darby, 30 Church street, New York, and in the employ of the American Steel Foundries, suggested the winning name, Onepiece, which the judges today selected as the most appropriate one, in that the plug is really a one piece construction, as the insulation is cemented by baking process into the shell, giving a plug without gaskets, etc. In all over 2,200 letters were received in reply to the advertisements of the contest placed exclusively in the Class Journal publications, THE AUTOMOBILE, *Motor Age* and *Motor World*.

Raise Ferry Rates on Automobiles

PHILADELPHIA, PA., Nov. 20—Automobilists are now compelled to pay an increase in ferriage rates on the Pennsylvania Railroad ferries between Philadelphia and Camden. This went into effect on November 17. The new rate for automobiles is 25 cents, which entitles four persons to ride in the car, and for each additional passenger riding in the machine ferry ticket sellers will collect an additional 3 cents. Under the old rate a flat charge of 25 cents was collected for each automobile carried between the two cities.

Factory Miscellany

MILLER Rubber Adds—The Miller Rubber Co., Akron, O., has let contracts for the erection of a two-story, 120 by 128-foot brick fireproof building, which will increase the present capacity to over 1,000 tires a day. Recently the company bought the plant adjoining its property, which was owned by the Franz Body Works. This will be partly rebuilt and used as a shipping department, while temporarily it serves as a garage, until the 60 by 100-foot garage is completed. At the rear of the plant a three-story, 40 by 110-foot warehouse is being built, while an extension to the rubber drying-room, 50 by 110 feet, is in course of construction. To take care of the additional factory space, which will total 272,905 square feet, or about 6 1-2 acres, a 2,000-horsepower plant is being installed. Complete extensions are expected to be finished by January 1.

Standard Tire's $25,000 Addition—Standard Tire & Rubber Mfg. Co., Willoughby, O., will build a steel factory addition at a cost of $25,000.

DeLion Tire Building in Trenton—The DeLion Tire & Rubber Co. Trenton, N. J., has started the construction of a large plant for the manufacture of its specialties.

Portable Garage Factory Planned—The Mower Portable Automobile Garage Co., Seattle, Wash., is planning to erect a factory for the manufacture of portable garages.

Hercules Tire's Plant—The Hercules Tire Co., Oakland, Cal., plans to construct a plant at Long Beach, Cal., for the manufacture of automobile tires. The plant will turn out about 190,000 tires annually.

Kelsey Wheel to Add—The Kelsey Wheel Co., Memphis, Tenn., will enlarge its plant to permit the manufacture of entire wheel frames for automobiles instead of spokes only, as heretofore; estimated reported cost $100,000.

Fifty Men Added to Gramm Plant—Fifty men will be added to the Gramm motor plant at Lima, O., which follows the announcement that the company has decided to increase the capacity of the plant and only turn out 1,350-pound trucks.

Apple Plant at Waverley—The Apple Electric Co., whose plant was formerly in Dayton, O., has completed the shipment of its machinery from that plant to its new factory in Waverley, N. J. The Dayton plant hereafter will be used only as a service and distributing station.

Bartlett to Establish Factory—Reginald Bartlett of Toronto, Ont., president of the Bartlett Automobile Co., has signed an agreement with Stratford, Ont., to establish an automobile factory there. The company is capitalized at $1,000,000. It will manufacture a medium-priced automobile.

Singer Co. Settled in Factory — The Singer Motor Co. is settled in the new factory in Long Island City. At the present time the company is turning out five cars a week, and by the first of the year will be increased to fifteen. There is also a complete service station where overhauling and painting are done.

Fisher Body Enlarging—A further enlargement of the Fisher Body Co., Detroit, Mich., is taking place. A six-story steel and concrete addition 80 by 112 feet is in course of construction and will cost $40,000, while to the present five-story building another story will be added, the enlarged plant to be 280 by 112 feet.

Motokart Plant in Scranton — Scranton is to have another industry. The plant of the Motokart Co., Peekskill, N. Y., is to be moved from that city to Green Ridge street, Scranton. The board of trade in the latter city will erect the building, which will cost about $60,000. The machinery of the company is valued at over $100,000. At present the company employs 200 hands, but within a year it may employ 1,000 hands.

Vaughan Plant to Be Marketed—J. P. Day has been appointed exclusive sales agent of the Vaughan Motor Car Co. one-story brick plant at Kingston, N. Y., which recently was remodeled by the Vaughan company. The property is located on the main line of the West Shore Railroad, sidings from which run into the plant. It is also equipped with a modern power plant having a 250-horsepower Corliss engine driving dynamos of 75 and 90 kilowatt.

Crawford's Spring Co. About Ready—The new automobile spring company in Lansing, Mich., will probably be formally announced in the near future, the $100,000 necessary for its organization having been very nearly subscribed for by local business interests. The inventor of the spring is W. H. Crawford, who has secured basic patent rights. The name of the company will probably be Crawford No-Shock Spring Suspension Co.

Milwaukee Westinghouse Plant Working—The Westinghouse Lamp Co., of New York, a subsidiary of the Westinghouse Electric Co., has commenced operations in its new western plant at Milwaukee, Wis., purchased some months ago from the Kissel Motor Car Co. of Hartford, Wis., upon the abandonment of the Kissell company's Milwaukee factory. The new Westinghouse plant will have an output of 600,000 Mazda lamps monthly, and it is said a considerable share of these will be low-voltage lamps for motor car purposes. The plant consists of five large buildings and is located on the main line of the C., M. & St. P. Ry. Co. at Thirty-first and Center streets, Milwaukee.

The Week in  the Industry

Motor Men in New Roles

COZZENS Joins Four Wheel Drive—Fred. H. Cozzens, formerly of the International Motors Co., New York, and the Peerless Motor Car Co., Cleveland, O., has been made Eastern and foreign sales manager of the Four Wheel Drive Co., Clintonville, Wis. He will have charge of truck sales in the territory east of Pittsburgh and north of Wilmington, N. C., and in addition will look after the foreign business of the company.

House Manager—G. A. House has been appointed manager of sales of the Auto Wheel Co., Lansing, Mich.

Greenwald Firestone Branch Manager—Lemon Greenwald of Ashland, O., has been made manager of a branch of the Firestone Tire and Rubber Co. to be opened at Santiago, Porto Rico.

Smith Blair Truck Manager—Charles Smith, formerly manager of the Newark Lumber Co., Newark, O., has resigned his position to become general manager of the Blair Auto Truck Co., Newark.

Knowles Milburn Assistant Manager—R. W. Knowles has been appointed assistant engineer of the electric vehicle department of the Milburn Wagon Co., Toledo, O.

Weaver Resigns—H. G. Weaver has resigned his position as publicity manager of the Haynes Automobile Co., Kokomo, Ind., to become sales manager of the Newell Motor Car Co., St. Louis, Mo.

Moore Saxon Sales Manager—Lawrence Moore, formerly in charge of the foreign sales department of the Saxon Motor Co., Detroit, Mich., has been made manager of sales both foreign and domestic.

Paxson Joins Regal—C. K. Paxson has been appointed a special representative of the Regal Motor Car Co., Detroit, Mich. Formerly he was general sales manager of the Ohio Motor Car Co., Cincinnati, O.

Shettler Resigns—Leon T. Shettler has discontinued his connection with the Grant company at Los Angeles, Cal., distributor and has joined the Earl C. Anthony organization, which has the agency for the Packard in southern California.

Blethen Heads Seattle Club—At the annual meeting of the Automobile Club of Seattle the following officers were elected: Joseph Blethen, president; W. A. Avery, treasurer; R. L. Sparger, vice-president, and F. M. Fretwell, secretary.

Jack Russell Chief Engineer—R. F. Jack has been appointed chief engineer of the Russell Motor Car Co., Ltd., Toronto, Ont. Mr. Jack comes from the Cadillac Motor Car Co., Detroit, where he was assistant chief engineer of that company.

McCune Kissel Manager—The Kissel-Kar Co. is the name of a new concern which has been organized with C. G. McCune as general manager to handle the KisselKar in central Ohio. The sales agency is located at 241 North Fourth street, Columbus, O.

Dalton Studebaker Assistant Branch Manager—F. N. Dalton has been appointed assistant branch manager for the Studebaker Corp. in Los Angeles, Cal. Mr. Dalton was called to Los Angeles from Salt Lake City.

Hinkle Heads Tire Co.—A reorganization of the Livingston-Hinkle Rubber Co., 186 East Gay street, Columbus, O., has been made by the retirement of G. E. Livingston. The entire concern will be operated by H. L. Hinkle under the name of the Hinkle Tire & Rubber Co.

Lansdale Krit Sales Manager—H. L. Lansdale, who was sales manager of the Krit Motor Car Co., Detroit, Mich., has been appointed general manager, replacing H. H. Crawford, who has resigned and who had the position since the Krit company was reorganized the latter part of 1913.

Jamison Resigns—C. F. Jamison has resigned his position as sales manager for the Saxon Motor Co., Detroit, Mich., to enter business for himself. Mr. Jamison long has been a member of the firm of Jamison Bros., Lafayette, Ind., implement and hardware dealers. It is understood that the firm will continue to handle automobiles.

Marshall Inter-State Representative—W. L. Marshall, formerly the Xenia agent for the Studebaker has become factory representative for the Inter-State factory, Muncie, Ind., and will cover ten counties in southwestern Ohio. The new distributing firm will be located at Dayton and will be known as the Twyman Motor Car Co., Dayton.

J. M. Studebaker Injured—J. M. Studebaker, Sr., of the Studebaker Corp., South Bend, Ind., was painfully injured November 19 in an automobile accident. The car in which he was riding and another car crashed together in a blinding snowstorm. Mr. Studebaker is 81 years old, but his injuries are not regarded as serious.

McDuffie Joins Los Angeles Firm—Joseph H. McDuffie, one of the pioneers of the automobile business in the United States, has become associated with the W. R. Ruess Co., Los Angeles, Cal., in the capacity of general manager. Mr. McDuffie is well known, as at one time he was connected with the McDuffie Automobile Co., Chicago, and until recently he was Western representative of the F. B. Stearns Co.

Myers Heads Baltimore Dealers—E. R. Myers, of the Motor Car Co., Baltimore, Md., was elected president of the Baltimore Automobile Dealers' Assn. at the annual meeting which was held November 11. He succeeds F. S. Bliven of the Standard Motor Co. The other officers elected were: G. B. Hall, of the Auto Outing Co., vice-president in the place of A. S. Zell, of the Zell Motor Car Co.; R. J. W. Hamill, of the Mar-Del Mobile Co., secretary-treasurer in the place of E. R. Myers. On the board of directors G. B. Hall was elected to take the place of Walter Scott.

Garage and Dealers' Field

Foreign Agent to Add American Cars—Watson & Co., 164 Broadway, Madras, India, at present importers and general distributors of motor cars and accessories, shortly will take the agency for an American car.

Electric Mfg. Opens St. Louis Branch—The American Electric Car Co. opened a branch house in St. Louis, Mo., recently, at 5029 Delmar boulevard, with Louis Goodhart as manager. The branch will be incorporated as the American Electric Car Sales Co.

Hartford May Be Motorized—If the recommendations made this week to the Mayor in the annual report of the Board of Public Safety are carried out, all horse-drawn vehicles in the police and fire departments of Hartford, Conn., will be displaced by motor cars as soon as the city's finances permit.

Large Garage in Centralia—St. John & Titus, Centralia, Wash., automobile and accessory dealers, are adding a concrete addition to their garage, 26 by 130 feet. This will be used for a tire and supply department and also for a showroom. A floor space of 12,000 square feet will be had with the enlargement.

Maxwell to Have Women Demonstrators—As a measure to increase the number of Maxwell sales to women customers the Maxwell Motor Co., Detroit, Mich., is to make a nation-wide canvass of all women's organizations for the purpose of engaging women demonstrators. It is stated that they will be paid at the same rate as the men already employed.

Recent Incorporations in the Automobile Field

New York

ROCHESTER—United Taxi & Delivery Co.; capital, $4,000. Incorporators: Julian B. Lewis, 23 Herman street; William Mayerson, 27 Gilmore street; Morris M. Dollts, 16 Herman street.

YONKERS—Morris Place Garage Co.; capital, $500; to operate a garage. Incorporators: Harry J. Haeussler, William H. Haeussler and William Haeussler, all of 45 Post street.

Ohio

AKRON—Superior Tire & Rubber Co.; capital, $25,000; to manufacture tires, etc. Incorporators: George S. Andrus, H. E. Andress, C. G. Wise, W. E. Young and R. I. Moore.

WILLOUGHBY—Standard Tire & Rubber Mfg. Co.; capital, $100,000; to manufacture tires and mechanical goods. Incorporators: Charles E. Shaw, C. F. Groth, E. A. Williams, J. W. Smith and J. A. Smith.

Tennessee

MEMPHIS—Bender's Garage; capital, $2,500. Incorporators: D. A. Fisher, C. N. Bender, L. G Bender, L. T. Kavanaugh and I. W. Crabtree.

MEMPHIS—Tennessee Garage Co.; capital, $10,000 Incorporators: Leroy H. Friedlander, Richard W. Burk, Dan L. Killain, A. D. Bearman and Joseph Friedlander.

Recent Incorporations in the Automobile Field

Arkansas

LITTLE ROCK—Butler Auto Co.; capital, $12,000; motor cars. Incorporators: F. L. Butler, Fremont Stokes and Mary A. Stokes.

Canada

LONDON, ONT.—Warwick Wheel Co. of Canada; capital, $100,000; to manufacture and deal in vehicle wheels, springs, tires, rims, etc.

TORONTO, ONT.—Noble Air Pump Co.; capital, $25,000; to manufacture motor car pumps and accessories.

Colorado

PUEBLO—Silver State Auto Co.; capital, $50,000.

Delaware

NEW CASTLE—New Castle Garage; capital, $25,000. Incorporators: S. C. Mulrooney, E. Krause and J. W. Brady, all of Wilmington.

WILMINGTON—Sharp & Rush Bros. Co.; capital, $75,000; to manufacture motor cars, wagons, etc. Incorporators: F. R. Hansell, Philadelphia, Pa.; G. H. B. Martin and S. C. Seymour, both of Camden, N. J.

Georgia

SAVANNAH—Dupon Auto Livery Co.; capital, $1,000; motor cars. Incorporators: R. A. Hicks and F. T. Dupon. (Central Press Bu.)

Illinois

CHICAGO—Automobile Clearing House; capital, $1,000; to manufacture, repair and deal in motor car repairs and accessories. Incorporators: R. E. Gray, C. E. Hall and J. C. Morrow.

CHICAGO—Century Auto Top & Supply Co.; capital, $10,000; to manufacture and deal in motor car supplies. Incorporators: B. M. Goff, C. A. Wever and B. M. Govy.

CHICAGO—Flanders Electric Co.; capital, $25,000; to manufacture electrical appliances. Incorporators: J. P. O'Shaughnessy, J. P. Rosen and J. L. Toohey, all of Chicago.

CHICAGO—Gas-O-Co.; capital, $20,000; to buy, sell and deal in gasoline, kerosene, electricity and all other commodities for motive power. Incorporators: Herbert K. Greenman, Arthur W. Brintell and Jacob A. Prassel.

CHICAGO—Lyon Tire & Rubber Co.; capital, $10,000; to manufacture and deal in tires. Incorporators: Leroy Harris, A. W. Lemke and W. B. Lathrop.

OAK PARK—Harrigan Auto Co.; capital, $5,000; to manufacture, lease, repair and deal in motor cars and other conveyances. Incorporators: George Von Moos, Agnes Von Moos and Thomas J. Harringer.

Indiana

INDIANAPOLIS—Hartman Top Co.; capital, $5,000; motor car and vehicle tops. Incorporators: Lawrence C., R. H. and L. M. Hartman.

SOUTH BEND—Teschner Tire & Equipment Co.; capital, $1,000; to deal in motor car accessories. Incorporators: Frank A. Teschner, Z. P. Teschner and Charles F. Roth.

Kentucky

HENDERSON—White-King Motor Co.; capital, $2,500; to deal in motor cars. Incorporators: Larkin White, Herbert L. King and Ben T. White.

LOUISVILLE—Orolo Mfg. Co.; capital, $10,000; general motor vehicle business. Incorporators: William H. Roose and others.

LOUISVILLE—Overland-Louisville Co.; capital, $10,000; to deal in motor cars. Incorporators: James H. Limbird, Robert H. Green and Charles S. Lattin.

SOMERSET—G. & O. Taxi-Service Co.; capital, $1,200. Incorporators: F. E. Gregory, W. H. Girdler and others.

Massachusetts

BOSTON—Apex Carbureter Co.; capital, $75,000; others. to manufacture carbureters. Incorporators: G. E. Parker and K. F. Parker, both of Boston, and others.

BOSTON—Johnson Pneu-Metal Tire Co.; capital, $1,000,000. Incorporators William P. Meehan and others.

Michigan

DETROIT—Automobile Owners Protective Association; capital, $10,000. Incorporators: Isaac Applebaum, Mark Mitchkum and Louis Applebaum.

DETROIT—Berry Automobile Pump Co.; capital, $10,000. Incorporators: Charles Retter, William W. Gunn and Henry J. Berry.

DETROIT—Cincinnati Precision Lathe Co.; capital, $12,500; to manufacture lathes and special machinery and tools. Incorporators: Albert M. Farlner, G. McHenry and others.

DETROIT—Disco Electric Starter Co.; capital, $60,000. Incorporators: Jacob and Henry J. Dornbus, Charles J. Carpenter.

DETROIT—National Electric Starter Co.; capital, $10,000. Incorporators: Trevor S. Murton, Harold K. Murton and Frederick M. Guy.

DETROIT—Wagner Resilient Wheel & Tire Co.; capital, $500,000. Incorporators: William F. Wagner, William F. Fergison, G. H. Karlcofe, W. E. Russell and A. C. Baird.

JACKSON—Jackson Cover & Bag Co.; capital, $12,000; to manufacture motor car covers of paper and cloth.

SAGINAW—Letts Auto & Taxicab Co.; capital, $12,000; motor cars and supplies. Incorporators: F. L. Butler and others.

TRAVERS CITY—West Michigan Garage; capital, $6,000. Incorporators: James B. Martin, William S. Titus and Alvin E. Hill... William P. Crotser, R. E. Wynkoop and James Purvis.

Missouri

LAWRENCEVILLE—Automatic Eagon Brake Co.; capital, $10,000. Incorporators: Olin E. Gillett, William S. Titus and Alvin E. Hill.

ST. LOUIS—Gerdelman Auto Supply Co.; capital, $10,000; general motor vehicle business. Incorporators: Benjamin Gerdelman, Rudolph L. Gerdelman and Lotta Gerdelman.

ST. LOUIS—Koehler-Woodruff Auto Repair Co.; capital, $2,000; general motor car and repair business. Incorporators: Frank J. Koehler, Leslie Woodruff and Henry J. Kroeger.

North Carolina

SALISBURY—Piedmont Automobile & Truck Co.; capital, $25,000; to deal in motor cars, etc. Incorporators: W. A. Brown and others.

New Jersey

TRENTON—B. & K. Specialty Mfg. Co.; capital $50,000; to manufacture rubber goods, hardware, electrical appliances, etc. Incorporators: L. W. King, S. Berman and U. G. King, all of Trenton.

WESTWOOD—Bergen Machine & Auto Repair Co.; capital, $30,000; general motor car and machine shop business. Incorporators: J. B. Haskin, New York, N. Y.; P. S. Schultz, West wood, N. J.

New York

BROOKLYN—Sterling Auto Exchange; capital, $10,000. Incorporators: Charles Erickson and William C. Lohse, both of 622 Pacific street; Henry Meier, Farmingdale, L. I.

BROOKLYN—Universal Tractor Co.; capital, $15,000. Incorporators: Florence O'Sullivan, 120 A Rockaway avenue; Charles Roessle, 907 New York avenue; Joseph Woodcock, 181 West street.

HEMPSTEAD—Topford Detachable Limousine Co.; capital, $50,000; to manufacture motor car bodies, etc. Incorporators: John A. McAvoy and William Hutchinson, both of Hempstead; Frank C. Cadden, 200 Fifth avenue, New York, N. Y.

NEW YORK—Boska Mfg. Co.; capital, $100,000; to manufacture rubber tires and tire fillers. Incorporators: Charles F. Saunders, 164 Sherman avenue; R. W. Wason, 607 W. 139th street; Simon F. Peavey, Jr., 151 Columbia Heights, Brooklyn.

Accessories for the Automobilist

NEW Champion Priming Plug—The Champion Spark Plug Co., Toledo, O., has brought out a new type of priming plug, Fig. 1, especially adapted for winter use.

It is similar to the former priming plug of Champion make so far as the combination of a priming cup with a plug is concerned, but it has the new features of a handle for turning the needle valve so as to admit the gasoline to the cylinder, and also a new steel needle valve, hardened and ground to a compression-tight seat in the priming portion of the shell.

There is an opening in the top of the needle valve for insertion of the oil-can nozzle. Having filled the priming cup, which is the inner part of the needle valve itself, the valve is raised from its seat by turning the handle. This allows the gasoline to flow through the side of the valve and down through its own channel to the plug base. Thus vaporization occurs directly past the ignition points, insuring ignition at once. The price is $1.25.

Advance Ford Pump — A power tire pump driven through the fan has been brought out by the Advance Machinery Co., Toledo, O., for Ford cars exclusively. It lists at $6.50. It is a double-acting type, Fig. 2, with a compression space at either end of the piston, which is driven by a yoked connecting-rod.

The fan shaft or journal stud is replaced by a shaft that rotates in the pump frame. The fan is rigidly secured to this shaft, on the opposite end of which is secured a driving pinion. This driving pinion engages with a steel gear supported by an eccentric bearing, thereby providing a means whereby the pump may be engaged or disengaged with the driving pinion.

The piston is packed with three piston rings at each end. These rings preclude any possibility of oil reaching the tire tubes.

The cylinder heads are removable. They are machined so that the clearance space between the cylinder head and the piston does not exceed the thirty-second of an inch.

The discharge valves are located at the end of the piston stroke. They are quarter-inch steel balls retained by light springs.

The cylinder is lubricated by means of wicks located in the middle of the body. The wicks are saturated with oil. All other bearings are oiled direct.

Easyon Tire Chains—The device shown in Fig. 3 has just been put on the market by the Leather Tire Goods Co., Niagara Falls, N. Y., to prevent skidding and give traction when the wheels tend to slip. Eight of these go to make up a set and they are attached to the spokes of the wheels. The part of the chain coming into contact with the wood of the wheel is made of leather, while the portion touching the tire tread is rounded so that it will not cut the tire. Four chains are used on each rear wheel. These chains are made in two sizes, the small size fitting 2, 3.5 and 4-inch tires, and the larger size fitting 4, 4.5 and 5-inch tires.

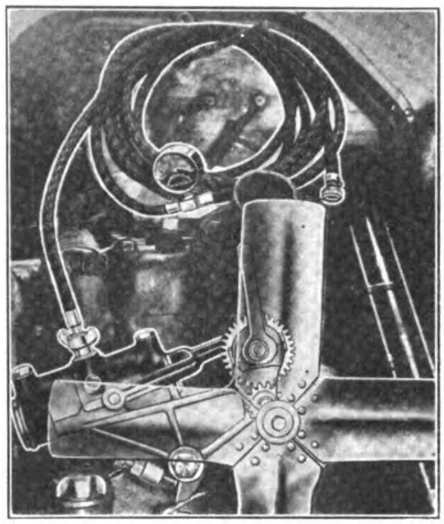

Fig. 2—Advance Ford pump driven by fan

Fig. 3—Easyon tire chains

Dudly Folding Shovel—An all-steel shovel, Fig. 4, of the folding type, with a blade 6.5 by 9 inches and a 3-foot handle, has been brought out by the Dudly Tool Co., Menominee, Mich.

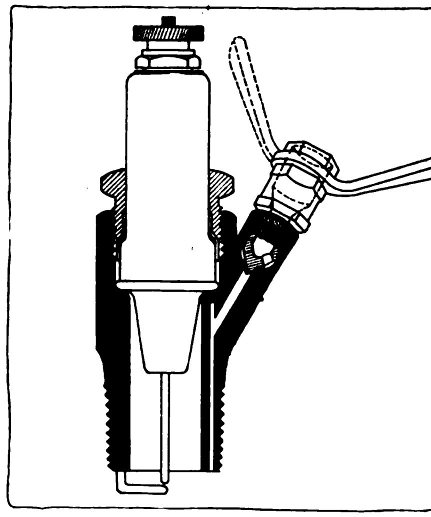

Fig. 1—New Champion priming plug

It makes it possible for the tourist to dig himself out quickly when stalled in the mud. In addition the blade of the shovel may be used to place the jack on when the ground is soft.

The weight of the shovel is 4 pounds, and it occupies a space 12 by 6.5 by 2 inches when folded up. It is nickel-plated and sells for $3.

J-M Tirenew and Narco Filler—J-M Tirenew is a compound of Para rubber in liquid form for use as a coating for tires. While adding to the appearance of the tires by making them clean and fresh-looking the makers insist that this is by no means its chief value. It is claimed that this compound penetrates into the cuts and crevices and thoroughly waterproofs the exposed fabric beneath, thus preventing decay from moisture and oil, and greatly prolonging the life of the tire.

For use in connection with the above, the makers recommend J-M Narco Tire Cut Filler, a combination cement cut filler and mastic, heavy in rubber. This substance fills the cuts and holes in a tire, welds the loosened tread to the casing and, it is claimed, forms a union so perfect as to be immune to the effects of road abuse. It sets over night and is said to be absolutely non-shrinking.

To restore and preserve automobile tops there is a special Narco product called J-M Narco Rubber Reviver and Refinisher. It is not a varnish, but a liquid rubber compound with an absolutely invisible protecting coat that waterproofs pantasote, mohair, fabric or rubber, with equally good results. One coat, it is asserted, lasts a long time.

In addition to the foregoing, the J-M Narco line also includes patching and vulcanizing cements of the highest

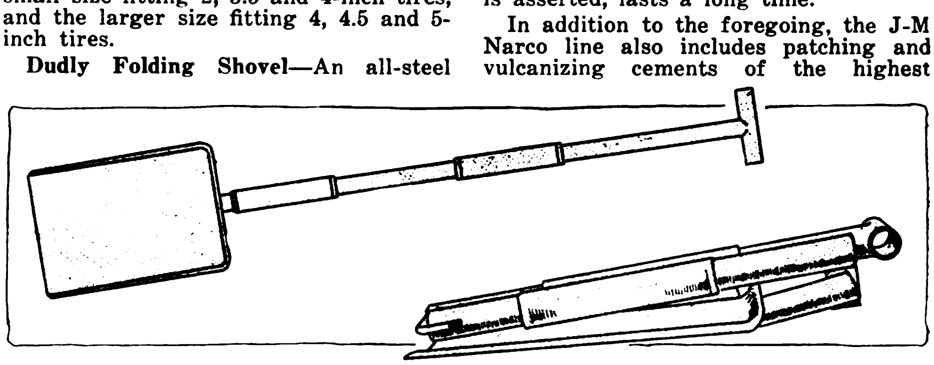

Fig. 4—Dudly folding shovel

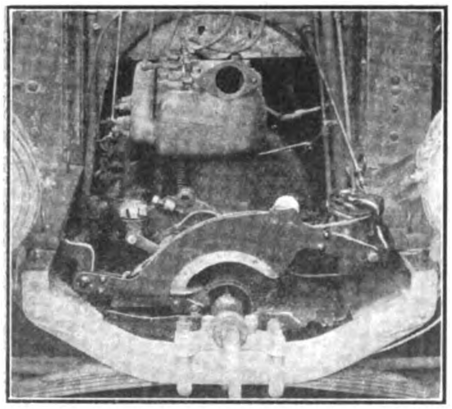

Fig. 5—Denver Ford starter

grade and special' cementless patches that may be used successfully without cement or acid. For the convenience of car owners who operate a small vulcanizer, four vulcanizing outfits are regularly supplied each containing enough for several jobs. Another very handy outfit for making inexpensive and satisfactory home and roadside repairs is the J-M Narco Ford Tire Repair Outfit, which contains a repair for every tire trouble that might possibly be met on the road, also several preventatives. This compact outfit can be carried in the tool kit and in time of need is a friend indeed.

The products are marketed by the H. W. Johns-Manville Co., 41st street and Madison avenue, New York City.

Denver Ford Starter—A mechanical starter, Fig. 5, of the pull type, weighing only 10 pounds, and fitting readily between the fan belt and the fan, is made by the Denver Ford Starter Co. A pull on the hand lever always connects immediately with the crank shaft, no matter where the engine happens to rest, and a 12-inch pull turns the engine over completely and quickly.

The device is entirely concealed and is bolted to the frame with two forward fender bolts. One distinctive feature is that it is not necessary to remove the crank or any part of the car to install the starter. A new fan belt pulley with a wider rim than the regular pulley, however, is furnished. The power is applied directly to the crank shaft without ratchets or cogs, two jaws gripping the rim of the fly-wheel the moment the lever is pulled. The method of connection is on the principle of slipping the jaws of a monkey-wrench over the rim of a fly-wheel and making the open wrench grip the rim by a pull downward. This method, made secure by a short, sharp jaw on the outer side of the rim, does away with slipping and allows scarcely any friction.

In case of back fire, the hand lever is automatically released by a rest on which it is seated.

This starter is adapted to both Ford and Metz cars. It sells for $15.

Garford Ford Speedometer—At $12.50 the Garford Mfg. Co., Elyria, O., is offering a speedometer for Ford cars which has a 100-mile trip odometer and a season mileage register of 100,000. The principle involves the centrifugal movement of steel balls which raise a cup in direct proportion to the speed of the flexible shaft. The construction employs a revolving drum or ball race mounted directly on the main driving shaft. This ball race has radial openings or channels

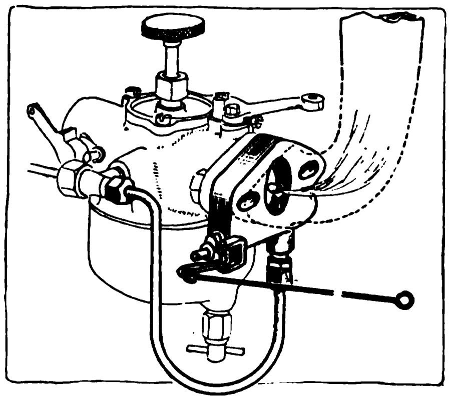

Fig. 6—Injex applied to Holley carbureter

containing four ½-inch steel balls. Fitting over this ball race and arranged to move vertically in line with the main shaft is an inverted cup-shaped member of steel with the inner surface so de-

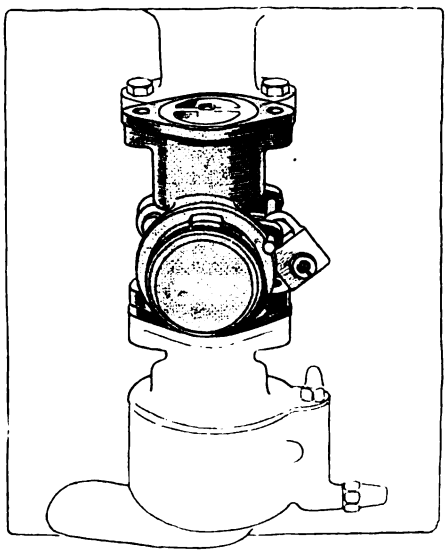

Fig. 8—Kramer self-contained engine governor, which is placed between the carbureter and the intake pipe

signed that the centrifugal movement of the steel balls in these radial grooves will raise the cup in direct proportion to the speed of the shaft. This vertical motion of the cup is transmitted to the indicating hand through a very simple lever arm. There is one spring used in the entire system and it is used to bring the indicating parts back to zero.

Injex Primer—To allow easy starting of the motor in cold weather the Reflex Ignition Co., 211 High avenue, Cleveland, O., has brought out the primer shown in Fig. 6 for $2.50.

By pulling a ring on the steering post or dash a spray of gasoline is injected from the feed pipe into the manifold.

The fuel is brought to the primer from the main gas line through a T pipe connection. Then by pulling the lever shown, a charge of gasoline is carried into the cylinder of the primer. On releasing the lever a strong spring forces the piston back and the gasoline is injected into the manifold.

Two types are made—one with a flange which is attached between the manifold opening and the carbureter, and the manifold type, which may be attached to any point of the manifold.

Kramer Governor—Controlling the speed of the motor by utilizing the velocity of the inrushing gases is the feature of a new governor made by the Kramer Governor Co., Detroit, Mich. As is shown in Fig. 9, as the speed of the motor grows higher, the increasing velocity of the gases past the floating disk in the intake passage raises this disk and closes the damper, placed below it. Thus when the speed of the gases reaches a pre-determined amount the butterfly begins to close and the speed drops. These two members are contained in a suitable casing which is inserted between the carbureter and intake manifold. Since it is compact and self-contained, it may be easily attached to any motor. There are no revolving parts and little to get out of order or wear.

It is stated that all governors are thoroughly tested and set for a maximum speed of about 1,000 revolutions per minute. The governor may be simply adjusted to any speed desired. This gives a direct control of the piston speed of the motor as the speed of the intake gases is a direct function of the piston speed. This is of course within the limits of ordinary running where the volumetric efficiency of the motor does not vary sufficiently to alter the proportions to an appreciable extent.

Imported ball bearings are used on the shaft of the butterfly valve and a clock spring regulates its action. The throttle shaft is ground true to 1-1000 inch. Hardened steel bushings are used in the links.

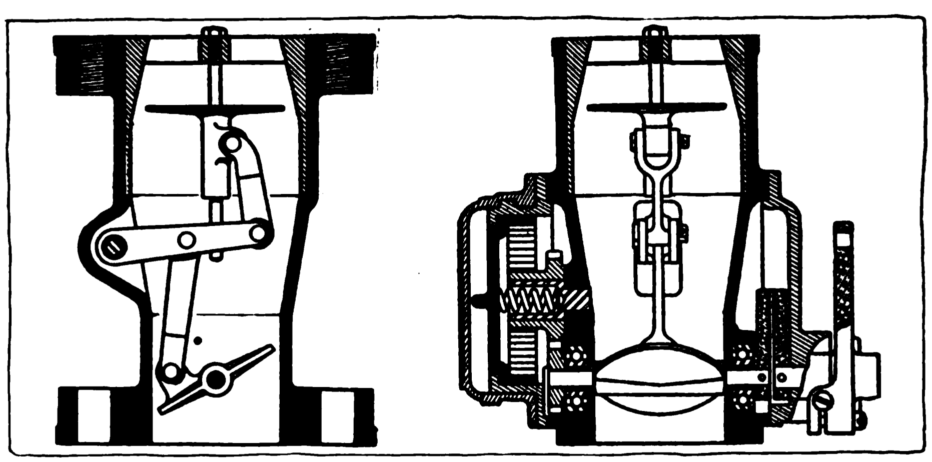

Fig. 9—Sections through Kramer engine governor showing operating disk which is raised or lowered according to the speed of the incoming gases, thus opening or closing the butterfly valve below

VOL. XXXI NEW YORK—THURSDAY, DECEMBER 3, 1914—CHICAGO No. 23

The AUTOMOBILE

Germany's Export Trade

An Analysis Revealing Opportunities—How the 1912 Foreign Business of $30,000,000 Was Distributed

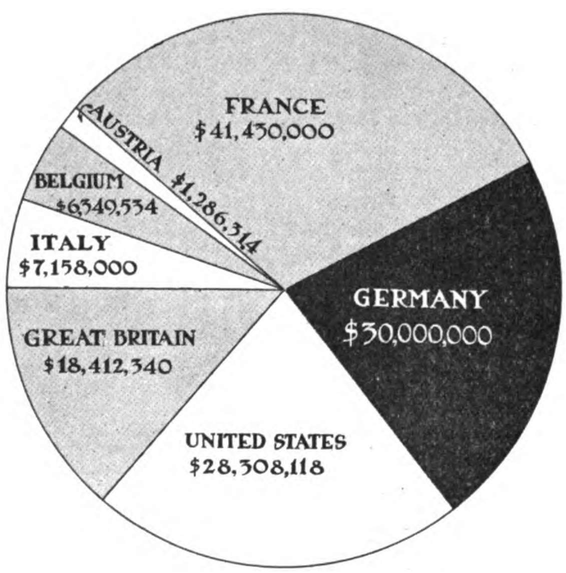
By Marc Braun

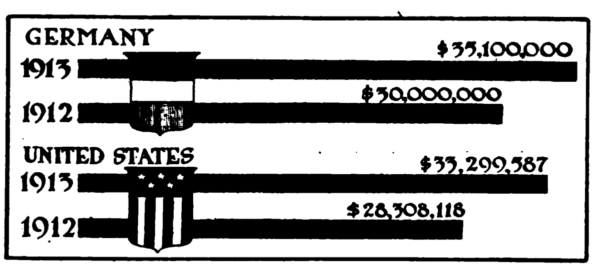
THAT Germany's exports of automobiles, motor trucks, parts, etc., for 1913 totaled $35,000,000 in value, or more than those of the United States for that year, will be news to a good part of the American automobile and allied industries. Exports of the United States covering these lines amounted to $33,299,587 in 1913, while for 1912 the statistics gave Germany's shipments a value of $30,000,000, as compared with $28,308,118 for those of the United States. Detailed information is not as yet available for 1913, but the 1912 statistics in themselves tell a story of the greatest interest to the automobile, commercial vehicle and accessory manufacturers of the United States, disclosing as they do the tremendous extent of their German competitors' influence throughout the world. In other words, owing to the war in Europe, the great markets which Germany has heretofore supplied would seem to be open to our enterprise. But let us see what an analysis of the 1912 exports of German makers reveals.

An Analysis

According to reports in the annual year book of German statistics, monthly bulletins and other official documents, information is available on German automobile exports to practically all the countries of the world except Austria, Italy, Turkey, Greece, Servia, Bulgaria and Roumania. Of these, however, the only ones of any importance are Austria and Italy.

Germany's shipments to the other nations of the globe totaled $25,078,118 for the year 1912. This figure includes automobiles, motor trucks, parts for both classes of vehicles and motorcycles. The countries to which the $25,078,118 worth of automobiles, trucks and allied products were shipped are: All of Europe except the seven countries named, all of Asia, Africa, Australasia, Mexico, Central and South America, the United States and Canada.



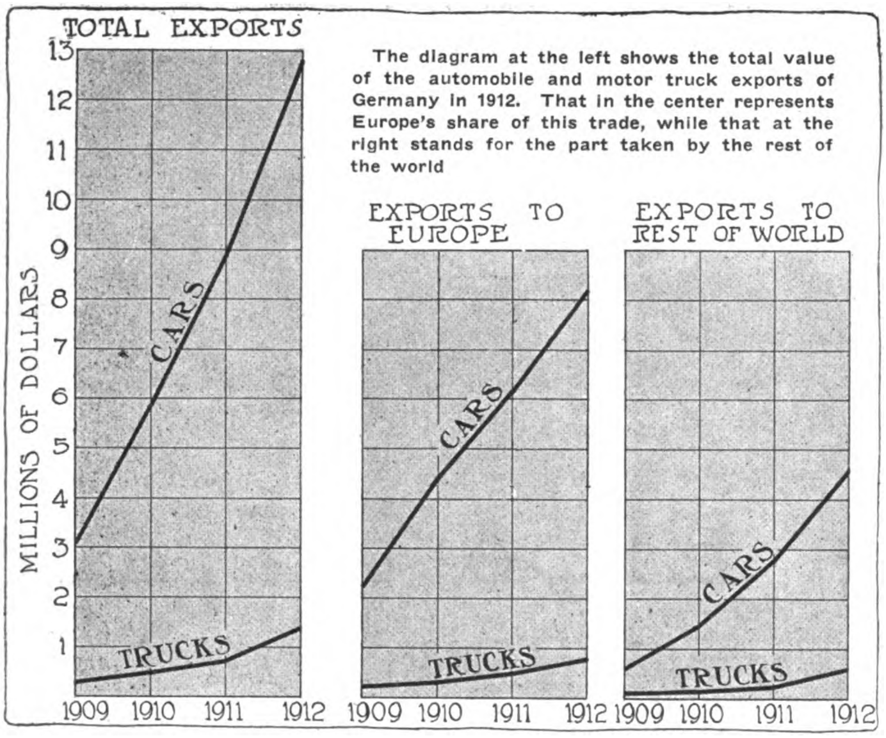


Above—Diagram showing relative value of automobile exports of the various nations. France leads with Germany second and United States third.
Below—A comparison of the export trade of Germany and the United States for 1912 and 1913

Europe's Share Largest

Naturally, the bulk of Germany's exports went to European countries, the total value of Europe's share being $15,945,834 in 1912, as compared with $8,470,-950 for the rest of the world, except the seven countries named and the United States and Canada, the total exports of Germany to the two last mentioned for 1912 being $258,250.

An idea of the importance attained by the German automobile and motor truck export industry may be gained from a comparison of the total values of cars, trucks, etc., shipped by other countries in 1912. An inspection of the chart on this page brings out clearly the fact that the world's export business in 1912 might be considered as divided into four parts, France, Germany and the United



The diagram at the left shows the total value of the automobile and motor truck exports of Germany in 1912. That in the center represents Europe's share of this trade, while that at the right stands for the part taken by the rest of the world

States each taking one and the rest of the countries, Great Britain, Italy, Belgium and Austria all together constituting the fourth.

France the Leader

France in 1912 was the great leader in motor car exports, her total figures for the year being $41,430,000. A further analysis of these figures show that of this total of French exports England took 27 per cent., Belgium 22 per cent., Algiers 7.8 per cent., Germany 7 per cent., Argentina 6.26 per cent., Brazil 5 per cent., Spain 2.4 per cent., United States 2.4 per cent., Switzerland 2.2 per cent., Italy 1.3 per cent. and Russia 1.2 per cent.

Britain Supplies Colonies

During the same year Great Britain exported motor cars and parts to the value of $18,412,340. Great Britain's exports are largely to her own colonies or possessions. Thus, in 1912, of her total automobile exports of $18,412,340 more than one-half went to her possessions, the exact figure being $10,765,500, as compared with a total export business on cars and parts to foreign countries of $8,397,970.

Belgium exported $6,349,534 worth of automobile products, her greatest consumers being Great Britain, Germany, France and Argentina, in the order named.

Italy's 1912 exports amounted to $7,158,000. Austria exported passenger cars and trucks to a total value of $1,286,314.

Returning again to the German industry: The information concerning automobile parts not being available for 1911, 1910 and 1909, we will deal principally with the motor car and motorcycle business only.

The Yearly Increase

Figures tell the story better than explanations. While in 1909 the German export trades in passenger vehicles represented a total value of $3,095,375, this increased to $5,859,350 in 1910, to $8,848,500 in 1911, and reached a total of $12,789,-550 in 1912.

Just as rapid was the increase in the commercial vehicle export business which totaled $301,500 in 1909, grew to $463,666 in 1910, rached $720,500 in 1911, and was almost one and one-half millions in 1912, the total being $1,405,734.

Motorcycles to a total value of $292,-250 were exported in 1909, while the following year the exports dropped to $254,-250. In 1911 the exports again increased, totaling $320,750, and in 1912 this total amounted to $471,250.

6,331 Vehicles in 1912

All told, the German manufacturers exported 6,331 passenger vehicles and chassis in 1912—not including the countries referred to above. The total value of these cars was $12,789,550 and the average price per car or chassis was $2,020.

The total number of commercial vehicles exported was 502, valued at $1,395,734 or an average of $2,780 each.

There were exported 2,352 motorcycles valued at $471,250, or $200 each.

Average Car Values

The average value of the passenger cars exported into European countries was $1,-924 and of those exported outside of Europe $2,025.

The total value of the automobile parts exported by Germany in 1912 was $10,-411,584 and it will be seen from the detailed statistics that fully 65 per cent. of the total represents automobile tires and inner tubes. Next in importance are motors and engines for automobiles and other vehicles.

Russia, the Big Buyer

Germany's best customer in Europe in recent years has been Russia, which purchased 1,120 passenger vehicles and 143 commercial vehicles in 1912, representing a total value of $3,152,500. The average price of the passenger car was $2,382 and of the commercial vehicle $3,386. The total increase of business over 1911 was a trifle over $1,000,000 and only a little less than $2,000,000 as compared with 1910, while in comparison with 1909 the increase was nearly $2,500,000.

Great Britain Second Buyer

The next best customer was Great Britain, which bought 1,072 passenger cars and twenty-four commercial vehicles or all told 1,096 of a total value of $1,886,750, which was an increase of less than $400,000 over the business of 1911. Including parts and motorcycles the total business of Germany with Great Britain in 1912 amounted to over $4,500,000.

France Slow on German Cars

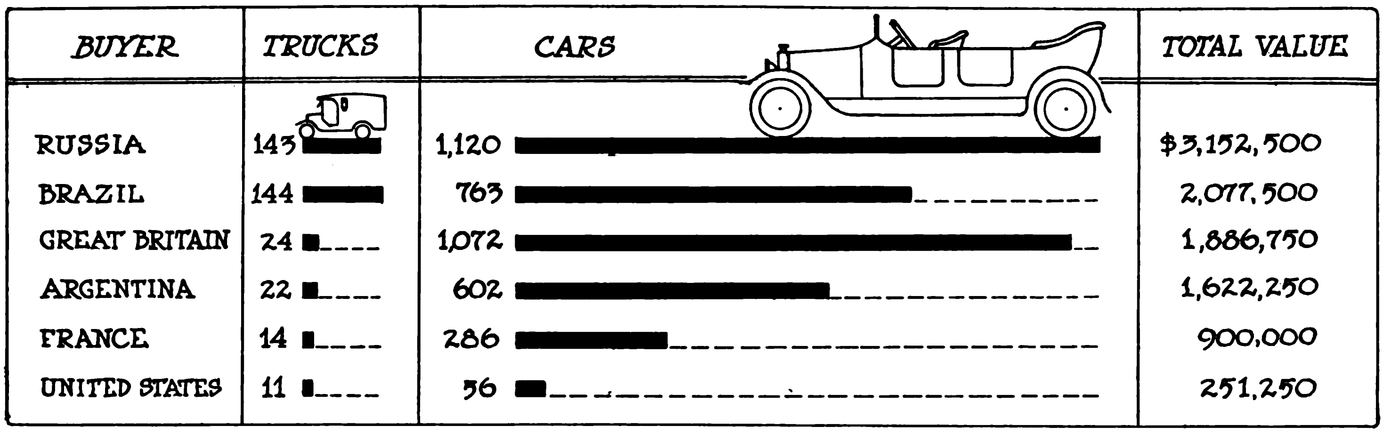
France imported only 300 German cars of which fourteen were commercial vehicles. The total value was about $900,-000, but with parts and motorcycles the total was more than $3,000,000.

France was Germany's second best customer for automobile tires, its purchases totaling $2,123,750, which was about $450,000 less than the British purchased of German tires in 1912.

Our German Imports

According to the government statements only fifty-six motor cars worth $220,750 were shipped to the United States in 1912 and their average value was $3,718, while the average value of the eleven commercial vehicles, worth $30,500 in all, exported to the United States was $2,772. Only thirteen motorcycles came to this country from Germany and their price was $211 each.

According to the German records the total value of the German cars, motorcycles and parts exported to the United



Chief buyers from Germany—A graphic representation of the number of cars and trucks and the total value in each case bought by the different leading countries from Germany in 1912. Russia, strange to relate, was the best customer, with Brazil second, Great Britain third, followed in order by Argentina, France and the United States

States was: $331,500 in 1909; $321,500 in 1910; $549,750 in 1911; and only $263,000 in 1912. This tremendous decrease of German imports into the United States in 1912 as compared with the amount purchased from the Empire in 1911, is a significant indication of the increasing influence of the American manufacturers.

In 1911 the German pleasure vehicles imported into this country represented a total value of $497,250. In 1910 the imported pleasure vehicles were valued at $265,250, and in 1909 their value was $271,000. In that year the imported commercial vehicles represented a value of $2,750, which increased to $17,500 in 1910, and to $23,500 in 1911.

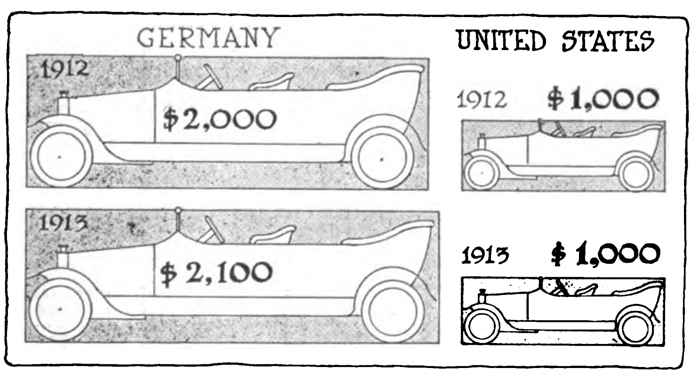
Small Canadian Business

The German business with Canada amounted to very little, totaling $18,250 in 1912, of which $14,000 represents automobile tires, $4,000 the value of two passenger vehicles and $250 the value of one motorcycle.

Quadruples in 4 Years

A table showing the grand total of German export trade of automobiles, parts, accessories and motorcycles with the most important countries in the world:

	1912	1911	1910	1909
PASSENGER CARS	$12,789,550	$8,848,500	$5,859,350	$3,095,375
COMMERCIAL VEHICLES	1,405,734	720,500	463,666	301,500
MOTORCYCLES	471,250	320,750	254,250	292,250
	$14,666,534	$9,889,750	$6,577,266	$3,689,125
PARTS	10,411,584	....	....	....
	$25,078,118	....	....	....



The diagram at the left represents the average value per vehicle exported by Germany in 1912 and 1913, while at the right is a similar illustration of the average value per vehicle for United States exports. The figures include both passenger cars and trucks

An analysis of this tabulation shows that this export trade has almost quadrupled in 4 years, growing from $3,000,000 in 1909 to $12,500,000 in 1912 in passenger vehicles alone. In commercial cars her exports have increased five fold in these 4 years.

Trade with Europe

The total value of the German export trade of automobiles, parts, accessories and motorcycles from 1909 to 1912 to countries in Europe only is shown in the following tabulation:

	1912	1911	1910	1909
PASSENGER CARS	$8,175,850	$6,045,500	$4,392,700	$2,476,475
COMMERCIAL VEHICLES	804,984	482,000	310,750	234,000
MOTORCYCLES	390,250	262,000	196,000	204,250
	$9,371,084	$6,789,500	$4,899,450	$2,914,725
PARTS	6,574,750	....	....	....
	$15,945,834	....	....	....

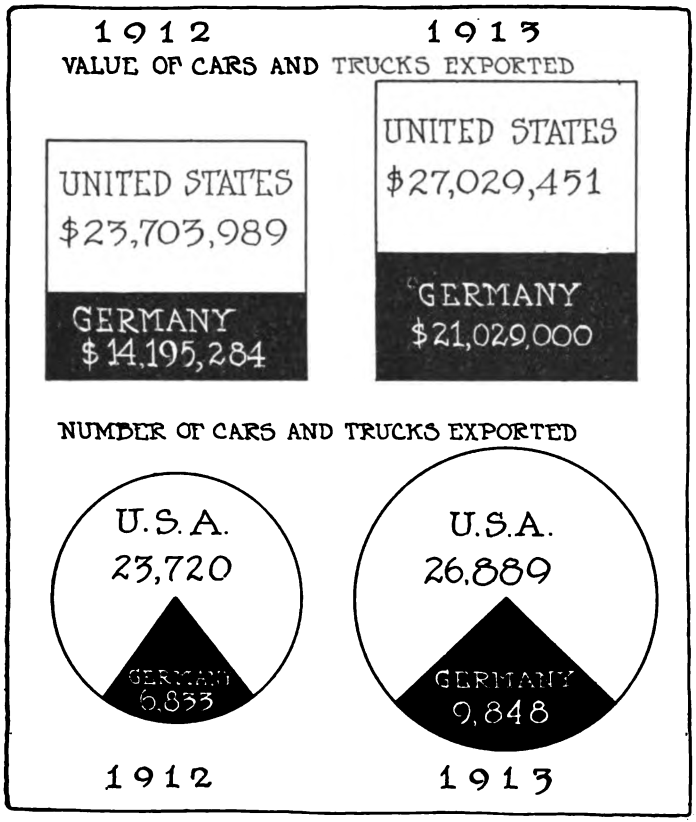
An inspection of the figures will reveal a story of greatly increased business, as the passenger car exports have more than tripled in the 4 years referred to; the truck business has similarly grown; and the motorcycle business has shown material gains. This condition of growth of exports is not local to Germany but applies to practically all European countries building cars except Austria and is largely due to the rapid development of the industry.

Business Outside Europe

To supplement the foregoing tabulation, the following statistics give the total value of German export trade in passenger cars, commercial vehicles and motorcycles to countries not in Europe, except the United States and Canada:

	1912	1911	1910	1909
PASSENGER CARS	$4,389,950	$2,305,750	$1,201,400	$347,900
COMMERCIAL VEHICLES	560,250	215,000	135,416	64,750
MOTORCYCLES	78,000	48,500	37,000	55,250
	$5,028,200	$2,569,250	$1,373,816	$467,900
PARTS	3,412,750	....	....	....
	$8,470,950	....	....	....

These figures aid those already quoted in bringing out the fact that the bulk of Germany's export trade is taken by



The upper diagrams represent a comparison of the total value of cars and trucks exported by Germany and the United States in 1912 and 1913 and the two lower charts contrast the number of vehicles exported by each of the two countries in these years. Note the greater number and lower average price of the American cars and trucks

European countries, but it must not be overlooked that German makers have extended their business into every quarter of the globe and have developed in a few years an export business of over $8,000,000 in countries outside Europe, the United States and Canada.

Exports, to South America, Africa, Asia, Australasia,

During 1912 Germany exported all told 2,241 automobiles valued at $5,028,200 to countries outside of Europe. The export trade in motor cars of the United States during that same year and to those same countries totaled 8,400 cars valued at $8,416,095 or an increase over the German business of nearly $3,500,000.

Americans Gain

Compared with 1911 the increase in business on the American side had been a little over $3,400,000 while on the German side the total showed an increase of only $2,500,000. The proportion of the increase of business is even greater for the American manufacturers for 1911 as compared with 1910, the total difference being $2,600,000 in favor of the United States and only $1,200,000 for the German manufacturers.

Comparing the German to the French export trade in 1912 to all countries outside of Europe, except the United States and Canada, and including parts, accessories and motorcycles, the official government records show that the value of the German exports totaled $8,470,950 while the total to the credit of the French manufacturers was $13,374,659 or nearly $5,000,000 more.

All the figures given in the charts or tables were taken from official German consular reports or from other official source. While the details for each country are available only for the year 1912 the totals are given for the years 1909 to 1911, and the data will give a fairly good idea of the rapid growth of the German automobile business with foreign countries which are now looking principally to the United States to supply them with these goods and others.

$2,000,000 Increase in 1 Year

Briefly stated, Germany exported $4,389,950 worth of passenger cars to South America, Asia, Australasia, Africa and Mexico during 1912, while the trade with those same countries in 1911 amounted to only $2,305,750, or a difference of over $2,000,000. In 1910 the total value of Germany's export business to all countries, excepting Europe, amounted to $1,201,400 for its passenger cars, which represented an increase of over $850,000 over 1909.

Truck Exports Double

The exports of commercial motor vehicles has followed about the same increase, its value in 1909 being only $64,750 while the following year it more than doubled, totaling $135,416. In 1911 the total was $215,000 and in 1912 it had increased to $560,250.

The motorcycle business has not followed the same ascending trend, for while in 1909 $55,250 worth of the little two-wheelers were exported, there was a sharp decline in 1910 when the exports showed a total value of only $37,000. The following year a gain of $11,500 was made, the total value being $48,500. In 1912 the German manufacturers had their banner year as they exported $78,000 worth of motorcycles outside of Europe.

$3,442,750 in Parts

For 1909, 1910 and 1911 the information for parts exported is not at hand, but for 1912 it totals $3,442,750 of which fully three-quarters represent tires and inner tubes.

$2,150 Per Car

All told, it appears from the records of the German government that only 2,241 passenger cars were exported outside of Europe in 1912 and their average value was $2,150. According to the detailed statistics per country the average value of the cars often varied, taking each country separately. Thus, for instance, the average value of the 763 passenger cars imported into Brazil was $2,183 while the average price of the 602 imported into Argentina was $2,582 or $399 more per car than those which went to Brazil. On the other hand, the average price of the thirty-six cars which were shipped to Japan was $1,660 or $523 less than those which went to

Analysis of German Passenger Car Exports in 1912

Passenger Cars and Chassis	No.	Value	Average Value per Unit
Exported	6,331	$12,789,550	$2 020
Sold in Europe	4,248	8,175,850	1,924
Sold outside Europe	2,025	4,389,950	2,167
Sold in U. S.	56	220,750	2,718

Analysis of German Commercial Vehicle Exports in 1912

Commercial Vehicles	No.	Value	Average Value per Unit
Exported	502	$1,395,734	$2,780
Sold in Europe	291	804,944	2,766
Sold outside Europe	200	560,250	2,901
Sold in U. S.	11	30,500	2,772

Brazil and over $900 less than those which were imported into Argentina. This is an interesting point as showing the trend of business in the different countries.

Trucks Average $2,801

The average price of the 200 commercial cars exported in 1912 was $2,801. The variance in average price per country was as marked as for the passenger vehicles. For instance those which went to Brazil averaged $2,858, those which were shipped to British Malaysia averaged $3,833 and those which went to Australasia averaged $2,125.

The average value of the 384 motorcycles exported was $203. The ninety-seven which went to Brazil averaged $219; the nine shipped to Mexico averaged only $166, while the twenty-seven purchased by Siam averaged $120.

A Steady Increase

The South American countries were Germany's best customers. The business in pleasure and commercial motor cars with Brazil totaled only $83,750 in 1909. One year later its total was $424,250. In 1910 it had come near the million dollar mark, totaling $826,750 and in 1912 it had passed the two million mark, the total being $2,077,500. The German trade with Argentina was about just as steadily on the increase, being only $82,500 in 1909 while in 1912 the total was $1,622,250.

2,801 Cars for Argentina in 4 Years

The German consular reports for the 4 years from 1904 to 1908 show that during that period a total of 2,801 automobiles were imported into Argentina and that 1,772 came from France, 348 from Germany, 236 from the United States, 216 from Great Britain, 180 from Italy, thirty-one from Belgium and nineteen from Spain.

During 1910 there were imported 1,610 cars, during 1911 the total was 2,473 and this reached 4,013 in 1912. About 39 per cent. of the cars came from France, about 25 per cent. from Germany, about 16 per cent. from the United States and about 13 per cent. from Italy.

The average value of the passenger cars imported by Argentina in 1912 was $2,582, while the trucks averaged $3,070. Motorcycles averaged $219.

Argentina's Growing Demand

The statistics representing automobile exports from all countries into Argentina in 1909, 1910, 1911 and 1912 are:

	1912	1911	1910	1909
	PASSENGER CARS			
602	$1,554,750	$619,000	$259,000	$80,000
	COMMERCIAL VEHICLES			
22	67,500	19,000	10,000	2,500
624	$1,622,250	$638,000	$269,000	$82,500
	PARTS			
...	*$853,000	......	......	....
	MOTORCYCLES			
41	$9,000	$14,750	$6,000	$6,500

*Includes automobile tire covers and tubes for $601,500.

One-Third of Brazil's Imports Are German

The imports of motor cars into Brazil increased from 735, valued at $1,123,400 in 1910, to 1,574, valued at $2,293,-700, in 1911, and to 3,785 of a total value of $5,368,000, in 1912. The average value per car for those 3 years was respectively $1,528, $1,457 and $1,418. One-third of the imported cars in 1912 came from Germany and one-fifth from the United States, while in 1911 the proportion was one-fifth for both countries. In 1910 the proportion was one-fourth from Ger-

NOTE.—No statistics were available on German exports of automobiles, trucks, etc., to Austria-Hungary, Italy, Greece, Turkey, Roumania, Servia and Bulgaria.

Fashion Hints for Winter Wear

Part II

NOWADAYS very few ladies who drive their own cars, or are used to the pleasure and convenience of riding about in them, let the weather conditions interfere with their frequent excursions into the realm of the open air. In a recent issue THE AUTOMOBILE reviewed and described the most up-to-date and most comfortable garments offered for the winter season for the masculine automobilist; herewith are similarly treated the latest dictates of Dame Fashion for the motoring lady who loves the snappy, zestful air of winter and the feel of the frozen road as the silent tires sweep the purring car briskly along.

A glance at the varied styles illustrated gives an idea of how carefully the supply companies have prepared for the winter trade. Almost every imaginable type of garment and accessory has been designed and manufactured for winter wear and great attention is given to include in the make-up of each article the qualities of comfort and stylish appearance. But look at the illustrations and you will recognize all these little features without further comment being necessary.

Ladies' raccoon coat finished with silk or blanket linings and designed to be at the same time comfortable, warm and becoming in appearance. While this is a midwinter type of garment, it will not be found too warm for the late fall and early spring. Auto Supply Co., $125 to $300. The silk-lined short gloves illustrated sell at $6.

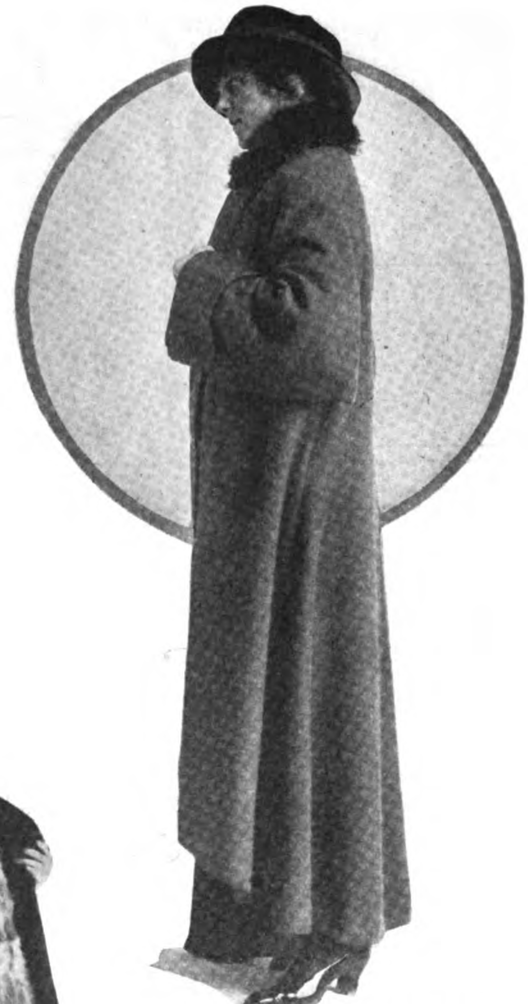
Cloth hat with velvet band. This shape presents a number of possibilities in the way of trimming and is sold either with or without plume. The hat will always be attractive and stylish. Smith-Haines, with plume, $7.50. Without plume, $5.

Above—An Angora wool muffler which is furnished in all colors and combinations. These mufflers are soft and warm, and are made long enough to prevent slipping loose, as may be seen. Auto Supply Co., $2.50 to $6.50. The velour hat illustrated is $10.

At the left—Retaino bonnet for ladies. The close-fitting shape prevents it from blowing off and its simplicity insures attractive appearance. The use of the bonnet with a veil is illustrated. Lowe Motor Supplies Co., $4.

Above—Automobile coat which comes in soft worsteds in all colors and combinations. The collar is convertible and the belt is an added feature of completeness in design. Auto Supply Co., $35 to $52.50. The velvet cap in all colors is $2.50 to $5.

Above — Another adaptation of the Retaino bonnet and a veil. This bonnet is slightly different in shape, material and construction from that illustrated on the opposite page and is a little lower in price. Lowe Motor Supplies Co., $4.

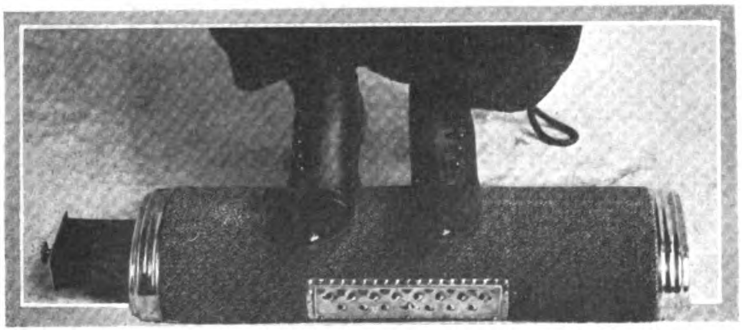


Above — Bedford cord robe for keeping the driver or passengers warm and cosy on a wintry day. The robe is made in all sizes and colors and is surprisingly light to carry, especially in view of its warmth-giving qualities. Auto Supply Co., $15 to $47.50. The cushion shown open is described at the bottom of the page.

A silk-lined coat with Australian opossum collar and well-designed set-in sleeves. The illustration gives an excellent idea of the becoming appearance of the garment, which is warm and cosy. Auto Supply Co., $40 to $55. The hat is the same as that shown at the left of the page.

Combination coat for wear in either street or car with large set-in sleeves and convertible collar. The material is worsted. Auto Supply Co., $30 to $50. The velour hat sells for $5 to $7.50.

Squirrel-lined coat with black fox collar. The coat material is black broadcloth. This is a very elegant, comfortable and becoming coat. It may be had in other material and different furs if desired. Auto Supply Co.. $75 to $1.50. The green plush hat is $5 to $7.50.



At the left is illustrated a charcoal foot warmer which comes in blue, maroon, black and gray, and in sizes from 12 to 24 inches length. The fuel drawer is pulled out at the left. Trimmings are nickel. Auto Supply Co., $2 to $10. The one illustrated is $10.

Leather cushion with pockets, shown open at the top of the page, for carrying veils, gloves, toilet articles, etc. This is a very useful article, especially for touring. The Retaino bonnet is illustrated on the opposite page. The cushion has handles for carrying it. Auto Supply Co., $6.50.

Left—Goggles with ball and socket joint over nose, allowing folding. The lenses are removable and interchangeable. There is provision for ventilation. A. J. Picard & Co., $1.50 with plain lenses. With amber lenses $2.

Right—Imitation tortoise-shell glasses for ladies' wear. They are made in one piece and do not fold or bend. A wide cheek-piece serves to keep out dust, dirt, etc. A. J. Picard & Co., $2.

At the left—Goggles of imitation tortoise-shell with gold-filled mountings and folding bows. The folding eye-cups serve to protect the eyes. These glasses are furnished with either amber or plain lenses and are light and comfortable. Lowe Motor Supplies Co., $1 to $5.

Above—Ladies' velour hat with buckskin band. This neat and serviceable sample of motor millinery comes in all colors and is both durable and comfortable, while at the same time being attractive in appearance. Auto Supply Co., $6.50.

One of the pretty silk mufflers which are furnished in all colors and combinations. They are of the best material and are soft, warm and of ample length to prevent slipping out of position. Auto Supply Co., $2 to $10. The hat is described on page 1014.

Photographs by Lazarnick.

New York Car Registrations Total 166,961

ALBANY, N. Y., Nov. 30—The records of the State Automobile Bureau show that registrations and receipts from fees for the first 9 months of 1914 are in advance of those for the entire year of 1913. According to the statistics from February 1 to November 17, there were 166,961 car owners registered as compared with 131,095 last year. Receipts from owners' fees this year total $1,283,895, a substantial increase over the $1,050,215, taken in during 1913.

An additional source of income is the chauffeurs' registration fee. To date there are 65,080 chauffeurs registered, 15,910 paying $5 fees, and 49,170 paying $2 fees. The fees total $177,890. In 1913 there were 55,185 chauffeurs registered who paid $157,866.

To November 17 this year there were 1,741 dealers registered in New York State, the amount of fees totaling $37,007. These figures compare favorably with the 1,735 dealers registered in 1913 and paying $37,080.

2,348 Foreign Cars

There were 2,348 foreign cars registered during 1914 to November 17 as compared with 2,134 in the preceding year.

Miscellaneous receipts totaled $16,871.86 as compared with $14,841.77. These miscellaneous receipts are made up of affidavit fees, lost plates, certificates, badges, etc. Vendee affidavits brought in $10,151 as compared with $7,116 for 1913.

In 1914 there are 1,355 numbers reserved, as compared with 1,017 in 1913. There are 418 registrations without fee, an increase of 108 over 1913. The commercial registrations without fee totaled 130 as compared with 75 last year. Owners' $5 fees number 68,059 and amount to $340,295. For 1913 these statistics were respectively 49,419 and $247,095. Owners' $10 fees number 50,764 and amount to $507,640 as compared with 42,176 fees amounting to $421,760 last year. The $15 fees totaled 18,894, bringing in $283,410. In 1913 16,762 fees brought in $251,430. This year $25 fees number 1,272, a significant decrease from the 1,358 of 1913.

Commercial fees of $5 were paid by 15,973 owners as compared with 12,263.

There are 60,628 original full rate numbers and 94,882 renewals. Last year the figures were 50,238 original numbers and 72,125 renewals.

There are 6,575 owners paying half rate or $2.50 in the $6 class as compared with $3,802 last year. When a car has been registered 4 years in succession it is entitled to half rate. In the $10 class 2,957 registered this year for $5. In the $15 class the half rate registrations totaled 925 and in the $25 class they amounted to 24.

Owners, Chauffeurs and Dealers Registered in New York State

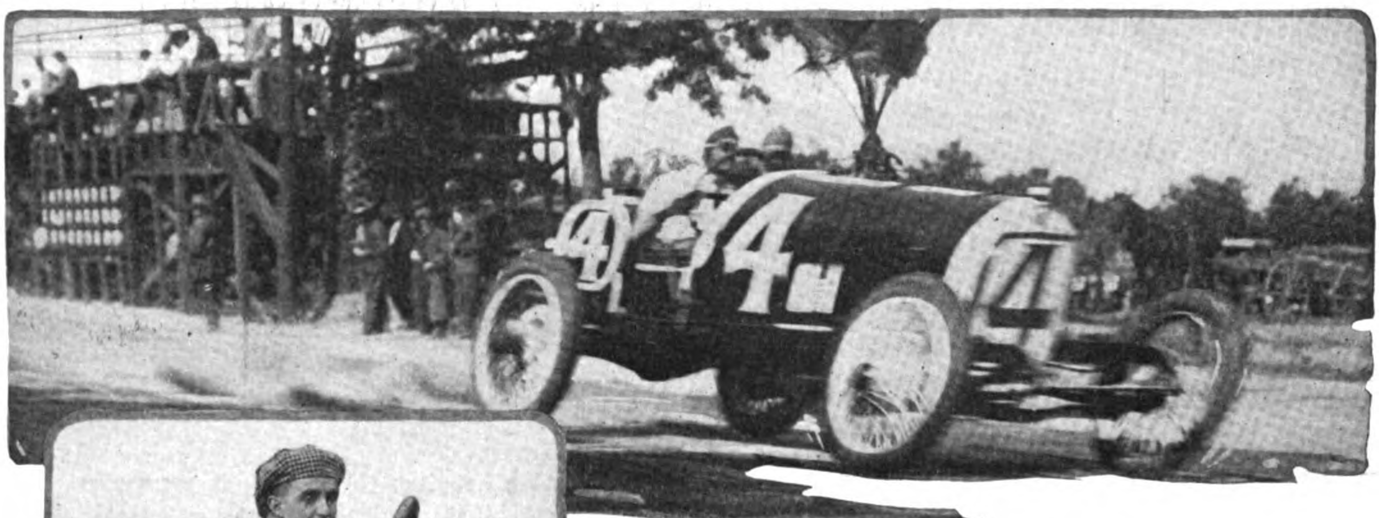
Pullen Wins Corona Race at 87.7 M. P. H.



Ed. Pullen swinging into the home stretch in his victorious Mercer which won the 301.89-mile road race at Corona, Cal., on Thanksgiving Day at an average speed of 87.7 miles per hour

Ed. Pullen, winner of the Thanksgiving Day road race at Corona, Cal., in his Mercer racer

Mercer Covers 302-Mile Course at a Record - Breaking Speed —Oldfield's Maxwell Second— O'Donnell, Duesenberg, Third

CORONA, CAL., Nov. 26—The greatest automobile race ever held on the Pacific Coast, the second annual Corona road race of 301.89 miles, was won by Eddie Pullen in a Mercer. He averagea 87.7 miles an hour, covering the 109 laps of the 2.76 miles in 3 hours 26 minutes 2 seconds.

It was a close, nerve-racking contest throughout. Pullen got the green flag at the finish, then Oldfield in the Maxwell shot across the line with O'Donnell's Duesenberg just 40 seconds behind. Less than 2 minutes after O'Donnell finished, DePalma crossed the tape in his Mercedes.

By capturing first place Pullen gets first money, the purse being $6,000; Oldfield in second place takes $2,500; O'Donnell wins $1,500 for third honors; DePalma $1,000 for fourth position; Gordon $750, or fifth money and Carlson takes the remaining $300 for sixth place.

Finishing Times in Corona Race

Car	Driver	Time	M.P.H.
Mercer	Pullen	3:26:02	87.7
Maxwell	Oldfield	3:29:58	86.3
Duesenberg	O'Donnell	3:31:12	86.0
Mercedes	De Palma	3:31:51	85.0
Gordon-Special	Gordon	3:48:29	84.0
Maxwell	Carlson	3:51:10	78.5
Mercer	Nikrent	3:55:10	77.2

How the Cars Went Out

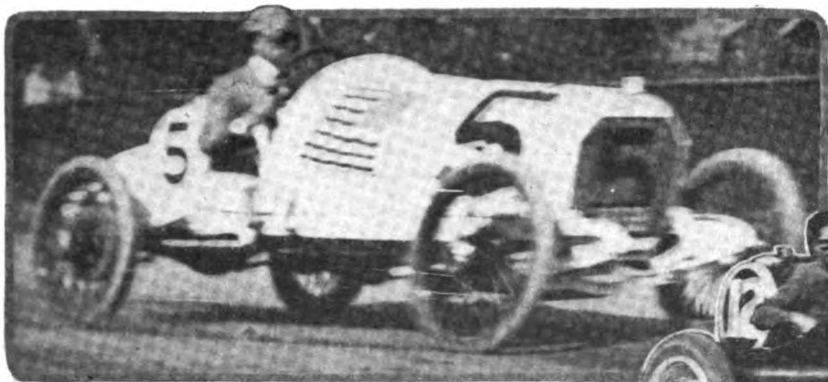
Car	Driver	Lap	How Eliminated
Marmon	D'Alene	1	Wrecked in smoke
Duesenberg	Alley	5	Broken clutch spring
Klein-King	Ball	30	Broken connecting rod
Peugeot	Rickenbacher	36	Transmission trouble
Stutz	Klein	34	Cracked cylinder
Stutz	Lewis	43	Broken bearing
Sunbeam	Grant	43	Burned up
Duesenberg	Callahan	58	Engine trouble
Marmon	Cadwell	63	Ignition trouble
Sunbeam	Babcock	88	Broken steering arm
Stutz	Cooper	107	Stripped timing gear
Mercer	Ruckstell	108	Out of gasoline

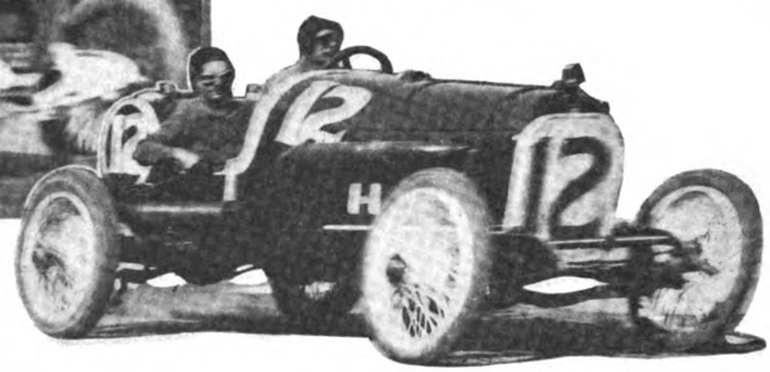
Pullen Takes the Lead

At the start Pullen took the lead and set a fast pace. For twenty laps he held the lead by a fair margin, averaging better than 96 miles per hour, with his right front tire giving way. When tire trouble set in he was thrown back several places losing practically a lap. Babcock in the Sunbeam, took the lead at the thirtieth lap and held the lead until the fifty-third lap when he struck a small dog and broke a steering arm. This was repaired and Babcock went back in the race but many laps behind, and when the eighty-seventh lap was reached, the repaired damage showed up again and the Sunbeam retired.

Earl Cooper in a Stutz held the lead from the sixtieth to eightieth lap when he was overhauled by Pullen and forced back into second position. Cooper held a close second from then to lap 108, when he went out with broken timing gears.

The only accident of the race was the wreck of the Sun-





Left—Huntley Gordon sending his Gordon Special along the last stretch of the Corona race. He finished in fifth place

Below—Louis Nikrent in Mercer No. 12 as the car appeared in the Thanksgiving Day road race over a 301.89-mile course at Corona

beam, driven by Harry Grant. The driver had built two 25-gallon gasoline tanks under the car. This was supposed to remedy the top-heavy trouble which has been claimed for the car. Grant was driving fast in fifth place on the forty-seventh lap, when a rear wheel collapsed. As the car had but about 6 inches clearance, the tanks dragged and sprung a leak. The scraping axle raising sparks on the course, set fire to the trail of gasoline. Before Grant could stop, the flames had caught up to the car and the fast racer was soon enveloped in flames. Unable to get out of the car, Grant and his mechanic, Harold Smith, were severely burned before they could get clear.

Early Eliminations

Almost from the start, the cars began to go out. The Marmon, driven by D'Alene, did not complete the first lap. Tom Alley, in the Duesenberg No. 20, was forced to retire at the end of the fifth lap with a broken clutch spring. The Klein-King, driven by Guy Ball, broke a connecting-rod and retired in the thirtieth lap.

The Peugeot, driven by Rickenbacher, held second position to Pullen's Mercer during the first twelve laps. A tire change was the first setback and in the thirty-sixth, Rickenbacher went out with transmission trouble.

Fast Stutz Speed

Arthur Klein, in the Stutz No. 2, averaged 98 miles an hour to the thirtieth lap when he stopped at his pit for a complete change of spark plugs. Going out again and traveling at a high rate of speed, Klein cracked a cylinder and was out. The cylinder had been welded the day before the race.

Dave Lewis, in the Stutz No. 3, was running in eighth position in the forty-third lap when a bearing burned out in the transmission.

A. A. Cadwell in the Marmon No. 11 changed a set of spark plugs in the sixty-third and after losing about twenty laps, returned to the race and was still running when he was flagged off the course after the last car in the money had finished.

Flying Speedway Start

At the start the leaders set a fast pace. This was largely due to the rolling start. The cars were lined up in sets of fours. It was a perfect start. The course was so fast that the drivers wore face masks, with one or two exceptions, to protect them from the small rocks thrown by other cars.

In the front rank were Oldfield, O'Donnell, Rickenbacher and Klein. The motors were started and the cars rolled around the course in a cloud of smoke. Oldfield tried for the jump at the start, but the starter held him back and when they got the flag, every car was in perfect position.

Nearly 100 M. P. H.

Averaging 98.6 miles an hour up to the thirtieth lap, the drivers circled the course like crazed demons, even Oldfield, said after the race that he never saw such a race and admitted that he was carried on by the speed of the others, realizing all the time that it was risky to do it, and expecting an accident at every turn.

When the cars began to thin out and the leaders came to the pits more often, the pace was cut down. From the third lap, Carlson, in Maxwell No. 17, had ignition troubles and was unable to get enough speed to catch the leaders. Louis Nikrent, in the small Mercer No. 12, did not have the speed of the other two Mercers nor the Gordon Special, which is a rebuilt Mercer. Nikrent drove a conservative and heady race, and finished just one behind the last money place.

DePalma, in the Mercedes, forged up to the front but when

the cars began to fall out, he dropped back and drove his usual heady race, but the course held the speed of the leaders and DePalma took only fourth place.

Oldfield was a feature of the race. He had only driven the Maxwell twice in practice for the race, and was not in physical condition. He said after the contest that he could have got more speed out of the car early in the race but as he did not know the machine, played safe. His non-stop record was one of the features of the race, however.

For 109 laps or 301.87 miles, Oldfield drove without a stop. Several times he was signaled from the pits to stop for oil and gas, but he shook his head and went on. Twice he had his mechanic open the tanks and look in to see how much fuel was left. This was done on the backstretch, where the course climbs about 100 feet, in the seventy-third and again in lap 103.

A Close Contest

At the end of the sixty-seventh lap with an average of 88 miles an hour, Cooper was in the lead, 48 seconds ahead of Pullen, and there were but ten cars left. Cooper was third and DePalma fourth, Ruckstell was in fifth place and O'Donnell sixth. Gordon and Carlson were together for seventh. At the seventieth lap Cooper still had the lead with Pullen a few seconds in his rear, but Ruckstell had taken third over Oldfield.

With a lead of 4 seconds, Pullen led the race at the end of the eightieth lap. Cooper was in second place; Oldfield third; DePalma fourth; Ruckstell having fallen back to fifth on account of a tire change, and taking on water, oil and gas. O'Donnell was in fifth.

When 100 laps had been covered, Pullen had the lead with 1 minute 36 seconds over Cooper. Ruckstell was third and O'Donnell had climbed into fourth over Oldfield.

This order continued until lap 108 when Cooper broke his timing gears. It was almost certain that Ruckstell would take second, giving the Mercer first and second, but on the last lap Ruckstell ran out of gasoline on the back stretch.

Close Finishes

Pullen finished amid the cheers of the 100,000 spectators who lined the course. Then came the Maxwell, driven by Oldfield, 40 seconds ahead of O'Donnell in the Duesenberg. Less than 2 minutes after O'Donnell finished, DePalma crossed the line. Fifth and sixth places were still in doubt and Gordon, Carlson and Nikrent were all the drivers left to fight for place. Although the Marmon was still on the track it was far in the rear.

Gordon had too much speed for Carlson, and took fifth. The last place went to Carlson, with Nikrent coming in eighth, four minutes out of the money.

It was truly a great race. There were 15,000 automobiles parked around the course and many thousands parked in the city back from the course. The attendance was estimated at 100,000. The first four cars to finish broke the world's speedway record and the road race record as well.

A new non-stop record was established and the Corona course which is now admitted to be the fastest in America with the possible exception of the Indianapolis speedway, is credited with the fastest time ever made.

Magneto Spark Vs. Battery-Coil Spark

Oscillograms Used to Show Characters of Both Sparks Wherein They Differ —Discharge Across Spark Plug Varies with Different Systems— Fuel Economy Directly Affected

By Dr. D. H. Cunningham

Chief Engineer, Splitdorf Electrical Co.

EDITOR'S NOTE.—*The oscillograms reproduced in this article were made by Dr. H. B. Williams and Dr. R. H. Cunningham, chief engineer of the Splitdorf Electrical Co., Newark, N. J. The experiments were made with an Einthoven string galvonometer in the Department of Physiology, Columbia University.*

NEWARK, N. J., Editor THE AUTOMOBILE:—The character of the spark bridging the gap in a spark plug with current from a magneto is different in many respects from the spark furnished by a battery-coil system and it is the purpose of this communication to show wherein these two sparks differ and how this difference affects the ignition of the explosive charge.

Why the Magneto?

Magneto ignition superseded old-time battery ignition by reason of its greater reliability. For, in addition to ignition troubles arising in connection with electro-magnetic vibrators, mechanical timers, and timer-distributers, the batteries proved to be non-durable and subject to rapid deterioration on standing.

Although the modern storage battery is a great improvement upon those in use 8 or 10 years ago, nevertheless experience teaches that even the present-day battery is far from being the dependable and durable reservoir for the storage of electricity which the exigencies of automobile ignition require.

The magneto, being a permanently excited electric generator, is always ready for its duties, requiring very little attention except an occasional drop of oil to its bearings and an infrequent adjustment of its platinum contacts. Unlike the storage battery, it may stand idle for months or years without attention and undergo no deterioration, being ever ready to deliver the required spark at a pull of the starting crank.

Battery Deterioration

All battery makers emphasize the necessity of care of the battery. The fluid electrolyte must be kept at the proper level. The battery must not be seriously overcharged, nor must its charge be allowed to fall too low, nor must too great an intensity of current be withdrawn from it at any time, for damage to the battery will result. In other words, the most important backstay of the automobile, the ignition, has for its anchorage, in the battery, a rather uncertain and variable foundation requiring constant care.

Promoters of the retrogressive innovation of return to ancint battery ignition glibly inform th uninitiated trusting intending purchasers that since the introduction of the lighting dynamo and its usually accompanyng electric starter, a reliable source of electric energy for the ignition will always be at hand; theoretically an alluring talking point for battery ignition, but in practice, seldom maintained for any great length of time. Mere observation at night of the lamps of the average automobile fitted with electric starting and lighting outfits, when standing with resting engine, usually demonstrates that few of their batteries are suffering from a plethora of overcharge. In fact, the lamps of most of the cars indicate that in but few of them are the batteries even normally charged, while in the majority the batteries appear to be undercharged.

Present-Day Gasoline

In former years when one bought gasoline, we received a fluid with a gravity of about 72 degrees Baumé. Nowadays we are lucky if we get gasoline of 65 degrees Baumé, and often we are handed lower grade gasoline of even 58 degrees Baumé.

This clearly indicates that what is now sold for gasoline is not the same kind of fluid as that of former years. Since the 72 degrees Baumé gasoline of former years was not a fluid of definite chemical composition, but was a fractional petroleum distillate composed chiefly of a mixture of hydrocarbons of the marsh gas or paraffin group, *it is evident that the lower grade gasoline of* 58 *degrees Baumé contains a smaller proportion of the more volatile components of the mixture and a greater proportion of the less volatile or heavier hydrocarbon members of the paraffin series.*

Gasoline Diagram

Without any great effort of the imagination one may readily form a crude mental picture of the probable microscopic structure of the charges of explosive gas obtained by carburetion of the above mentioned high-grade and low-grade gasolines. Thus, in diagram A, Fig. 1, the light space or white within the square may be considered to represent that part of the charge of gas that has been fully volatilized and thoroughly mixed with a requisite volume of air. The scattered globules of various sizes represent the various heavier hydrocarbon constituents that have been nebulized by the inflow of air through the carbureter during the suction cycle of the engine.

In diagram B, Fig. 1, representing a carbureted charge of a lower-grade gasoline, for instance, from gasoline of 58 degrees Baumé, as generally sold today, the space within the square is slightly shaded to indicate the more or less incompleteness of the volatilization, and many more nebulized globules appear in the explosive mixture. In other words, such a mixture consists practically of gasoline and kerosene and experience teaches us that the greater the proportion of kerosene present the greater is the difficulty of initiating the ignition of such mixtures by means of a thin *ionizing* spark of very brief duration.

While it is probable that ionization is intimately concerned in initiating ignition when a suitable explosive volume of a pure gas, such as methane* is used, my personal experience has been that where the mixture has been of a composition resembling more or less that depicted in diagram B, Fig. 1, namely, from 58 degrees Baumé gasoline, the use of a flame

*W. M. Thornton, Proceedings of the Royal Society May 28, 1914, page 272.

or arc spark of appreciable duration always proved to be the best form of ignition.

That the spark delivered by a properly proportioned and constructed high-tension magneto contains the so-called arc-flame is readily capable of demonstration, Fig. 2, by means of a sufficiently sensitive oscillograph; and furthermore, the intensity of current forming the arc and the time of its duration can be measured with considerable exactness, so that an accurate comparison can be made with the spark obtained from an induction coil actuated by a mechanical circuit breaker and current from a battery.

At each interruption of the primary current passing through an induction coil, the resultant spark or sparks have been demonstrated by scientists years ago to consist of but one single discharge of an extremely brief duration, or of several successive sparks or discharges, usually oscillatory in character and strongly damped.

Since the orthodox spark coil consists of two closely coupled mutually inductive electric circuits both containing inductance, capacity, and resistance, and since the terminals of one of these circuits, the high-tension or secondary circuit, are connected to the capacities of the high-tension cables of the plugs and of the frame of the automobile, with one or often more spark gaps included in the external circuit, it is probable that the secondary discharge over the spark gap or gaps is oscillatory in character, and it is evident that the frequency and damping of these oscillations will depend upon the magnitudes of the inductance, mutual inductance, resistance, and capacity of the circuits.

With the small induction coils usually employed with battery ignition, the magnitudes of the preceding factors are relatively speaking minute, while the frequency of the oscillations is correspondingly high and the damping strong. In fact, often the frequency of such oscillations is so high that it is hardly possible to obtain a photographic record of them, although their presence can generally be detected with a Gehrke oscilloscope or with a cathode ray or Braun tube.

Spark Character

In Fig. 3 is shown the current curve of a secondary spark delivered across a gap of .025-inch by a so-called single-spark timer-distributor. The capacities of the short high-tension lead and spark gap were very minute, and although a slight irregularity in the descending part of the curve can be detected on close inspection, the frequency of any oscillations present was entirely beyond the range of the instrument employed for their registration.

In Fig. 4, we have the curve of a spark from a larger two-section coil actuated by a type of interrupter that permits a preliminary closure of the primary circuit for 33 degrees. Inspection of the shape of this curve shows that oscillations were undoubtedly present in its descending portion, but their frequency was too quick for the instrument. In order therefore to more closely approximate to the conditions that are in an automobile when the spark plug gap is within a cylinder containing compressed gas, the gap was made .1875-inch, and a capacity equivalent to,—or in this particular instance, probably slightly greater,—that of the high-tension cable and of the frame, engine, etc., of a large six-cylinder motor. By this procedure, the frequency of the oscillations was considerably lowered, and a graph of the series of sparks composing the damped wave train is reproduced in Fig. 5. In other words, Fig. 5 is an analysis of the curve in Fig. 4, and shows that in reality the curve in Fig. 4 is nothing but a series of sparks of very brief duration and not so dynamic in exploding a charge as an arc such as shown in Fig. 2.

The spark plug gap is filled with electrons or ions which in an alternating field vibrate back and forth between the electrodes of the spark plug, Fig. 6. This is the alternation discharge we get with the induction coils such as illustrated in Fig. 5. In the magneto with a discharge similar to Fig. 2 the ions are projected out more into the surrounding gas, Fig. 7, and so tend to a quicker explosion. These ions radiate along the electrostatic lines in the field surrounding the electrodes of the plug. The ion is real parts of the electric charge of the atom and these inconceivable particles fly off

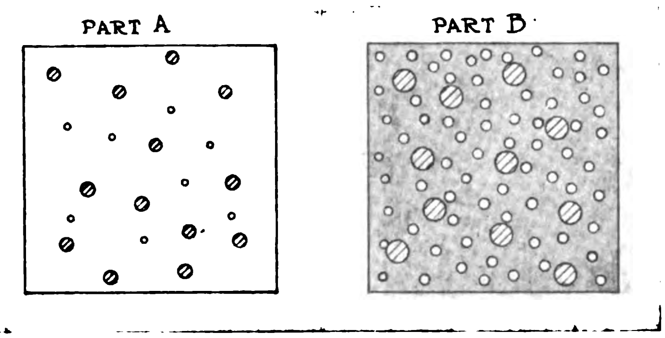

Fig. 1—Part A—Light portions represent fully volatilized part of a charge of gas while the scattered globules are the heavier hydrocarbon constituents nebulized by the inrushing air on the suction stroke

Part B represents a mixture of a lower-grade gasoline such as 58 degrees Baumé. Shaded sections show the more or less complete volatilization of the fuel. Note presence of numerous nebulized globules

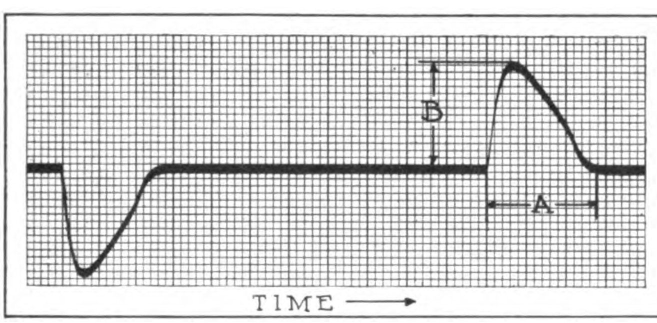

Fig. 2—Oscillogram of magneto high-tension spark bridging a gap in the spark plug .025 inch in length. The speed is 500 breaks per minute and the breaker box is in the retarded position. In this illustration the abscissae each section represents .001 second of time. The ordinates are 1 CM = .040 ampere. The maximum deflection indicated by the vertical line B = .058 ampere. The duration of the arc as indicated by the line A is approximately .0125 second. The maximum deflection B means maximum current which is synonymous with large volume and which characteristic is essential to the modern gasoline engine. The line A representing duration of the spark is interpreted as meaning that the current continues to flow across the gap in the spark plug for this interval

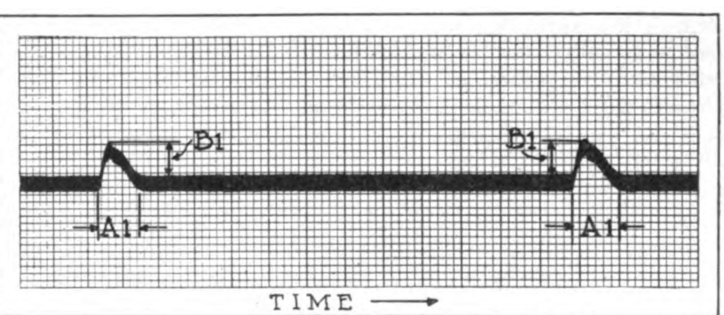

Fig. 3—This oscillogram of a high-tension current was made from a small induction coil actuated by a single-spark interrupter and a 6-volt battery. The gap over the spark plug was .025 inch, the speed 500 breaks per minute. In this illustration the abscissae, each section, represents .001 second time. The ordinates are 1 CM = .040 ampere. All conditions are the same as in Fig. 2. The line B1, which indicates the maximum current, is scarcely one-third in height of the line B in Fig. 2 indicating the same factor. The duration of the spark indicated by A1 shows it to be not one-half that indicated by A, Fig. 2. The frequency of any oscillations present was beyond the range of the instruments used for their registration, owing to their minuteness

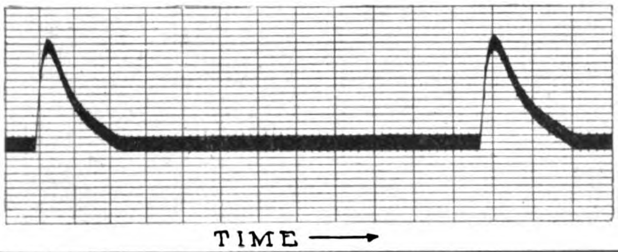

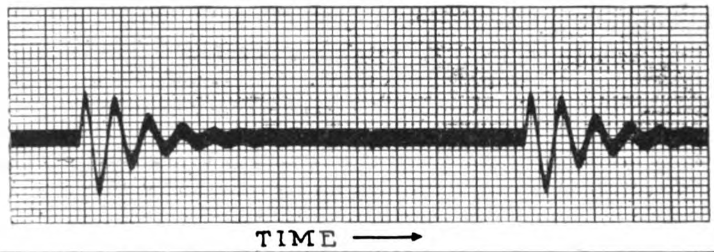

Fig. 4—Oscillogram of high tension current from large two-section coil actuated by a breaker allowing a preliminary 33 degree closure of the primary circuit. A 6-volt battery was used, the spark gap measured .025 inch, and there were 500 breaks per minute. Abscissae, one section, = .001 second. Ordinates, 1 CM equals .040 ampere. As is brought out in Fig. 5, which is in reality an analysis of the above curve, Fig. 4 is nothing but a series of sparks of very brief duration and not so dynamic in exploding a charge as an arc such as is illustrated in Fig. 2, which is that produced by a magneto high-tension spark

Fig. 5—A damped oscillatory discharge over a spark gap 3/16 inch in length. The coil, used in making this oscillogram was the same as in Fig. 4, namely, a large two-section one actuated by a breaker allowing a preliminary 30 degrees closure of the primary circuit. A 6-volt battery was used. In making this oscillogram the conditions were practically the same as in regular car use, namely, with compression as encountered in a cylinder. It will be noted that each discharge instead of being as in Fig. 4 is a series of very rapid sparks or discharges above and below the line. Abscissae, one section .001 second

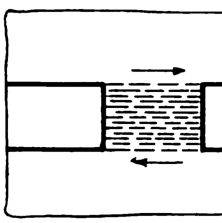
into the surrounding gas. Their action is somewhat similar to the mist that hangs in the air around the Niagara Falls. This mist is not a part of the cataract but an effect. The only difference with the ions is that they are radiated into the surrounding gas before the spark begins arcing over the plug, whereas in the comparison of the mist at the falls it follows after the water has been precipitated over the cataract.

Less Current Needed

WORKING WITH BREAK SPARKS OF DIRECT AND OF ALTERNATING CURRENTS, PROF. THORNTON FOUND THAT WHEN CONTINUOUS CURRENT WAS EMPLOYED, FIGS. 2 AND 3, LESS CURRENT WAS REQUIRED TO START IGNITION OF EXPLOSIVE MIXTURES OF GAS. HE ATTRIBUTES THE DIFFERENCE TO THE FACT THAT WHEN ALTERNATING CURRENT IS USED, THE RAPIDLY REVERSING ELECTRIC FIELD ACROSS THE SPARK GAP, FIG. 6, DRAGS THE IONS OR ELECTRONS FROM POLE TO POLE AND PREVENTS THEIR ESCAPE INTO THE GAS. WITH THE DIRECT CURRENT ARC THE IONS ARE PROJECTED OUT INTO THE GAS AND IGNITION IS MORE READILY INDUCED, FIG. 7.

High-Frequency Results

Apropos of the preceding results of Prof. Thornton is an experience that occurred to the writer some years ago during an investigation of the ignition qualities of a certain novel high-frequency magneto-ignition outfit. The spark delivered by this apparatus covered a gap of .5-inch in air, and appeared to be a veritable ball of flame. The effective high-tension oscillatory current from the small oscillator coil measured with a suitable hot-wire milammeter reached the high value of 350 milamperes, with the magneto-generator running at 1800 revolutions per minute. This ignition outfit was tested upon several different makes of four-cylinder motors with the uniform result that the engines were very sluggish, possessed little power on hills, overheated readily, and the speed of the cars lessened at least 50 per cent. From subsequent measurements and calculation the frequency of the oscillations across the gap was probably in the neighborhood of 300,000 per second.



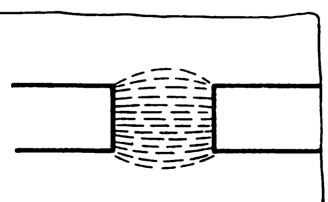


Fig. 6—Left—Diagram of the vibration of electrons or ions between the spark plug electrodes with an alternating discharge such as obtained with induction coils as illustrated in Fig. 5

Fig. 7—Right—Illustrating how the ions are projected out more into the surrounding gas by a magneto discharge such as that obtained in Fig. 2, tending to quicker explosion

Thin, Brief Spark

In other words, when a small induction coil is energized by a feeble primary current during a very brief period, as occurs in many of the present timer-distributor models, the resultant spark appears extremely thin, and is of such brief duration that often imperfect combustion of the explosive mixture with diminution of power results.

At high engine speeds, owing to the shortening of the time of closure of the primary circuit, the magnetic field of the coil does not have time to build up properly and hence the resultant sparks become progressively weaker and weaker and even fail altogether, unless a precaution similar to that used in the days of early battery ignition is taken; that is, the use of a type of timer in which the time of closure of the battery current through the primary of the coil is automatically increased as the speed of the engine increases.

Former experience with such appliances has demonstrated that, although these more or less complicated mechanisms frequently work well for a short time after their installation upon the car, ultimately they become loose, wabbly, out of time, and succumb to the effects of the action of grit, oil and vibration.

The Magneto Spark

Quite different, however, is the behavior of the spark from a high-tension magneto as the speed of the engine increases. Instead of growing progressively thinner it becomes hotter and hotter, until at about 1800 revolutions per minute of the armature, the maximum strength of the alternating current forming the arc-flame discharge between the spark plug points becomes approximately constant, and since each arc or spark lasts for an appreciable time and contains ample heat, it is evident that, as an ignition device for the highest engine speeds, so far nothing has been found that will fulfill the requirements as simply and effectively.

Spark at Slow Speeds

In former years, it must be admitted, that magnetos had not reached the perfection to which they have attained at present, nor was the present slow-speed, powerful gasoline automobile engine so much in evidence, hence to facilitate starting, or to be able to run on high gear at the very slow speed of 3 or 4 miles per hour, recourse had to be had to battery ignition. But high-tension magnetos capable of giving good sparks at 50 revolutions per minute are now made that will permit of this, provided the engine at such slow speeds is capable of propelling the car.

Advocates of battery-coil ignition extol the great advantage of the extensive range of spark advance necessarily provided with such outfits in order to compensate for the electrical lag inherent in such a system, but none draw attention to the fact, that in order to spark the engine with proper reference to its various speeds, almost constant manipulation of the spark advance lever becomes necessary. The closest attention of the driver is required at all times to maintain a smooth running of the engine. With modern types of magnetos, extensive range of advance is provided.

Simple Wiring

In the present combination of battery, ignition-lighting-starting outfits, one glance at the innumerable rat's nest of ignition cables, lighting cables, starter cables, cut-outs, and cut-ins, fuse boxes, etc., is enough to give one cold chills when he thinks of how he would be off for ignition were one or more short circuits to occur in that tangle of wires, when he is miles from anywhere on a stormy night. Generally, it means walking to the nearest garage and a tow, unless some good Samaritan in another car happens along.

On the other hand, consider the extreme simplicity of the wiring required by the usual high-tension magneto. Besides the requisite high-tension leads to the spark plugs only one wire leading to a simple grounding switch is necessary.

During the past season, numerous chauffeurs of cars fitted with battery ignition were interrogated for information regarding fuel consumption and car speed. Some of them having driven no car with magneto ignition could give no definite information, but none were enthusiastic concerning the speed of their car; all, in fact, admitted that their cars were not speedy. Many of them, however, were used to magneto ignition; in fact, a number of them had driven cars similar to what they had, but fitted with magneto ignition instead of battery ignition. Without exception, those with that experience regretted the fact that their bosses had bought the new model car fitted with battery ignition and expressed a very decided longing for their former cars with magnetos.

Where they had formerly with magneto ignition been able to get about 14 or 15 miles to the gallon of gasoline and had been able to attain a speed of 50 miles per hour, after the same type of car had been fitted with the battery ignition, they could get only about 11 or 12 miles to the gallon of gasoline, and could with difficulty get up to a speed of 40 miles per hour.—DR. R. H. CUNNINGHAM, Chief Engineer Splitdorf Electrical Co.

Baltimore Municipal White Truck Has Wireless Equipment

THE Electrical Commission of the City of Baltimore has placed in service a motor truck which performs an astonishing number of duties in the maintenance of the municipal conduit system. The truck was built by the White Co., Cleveland, O., and combines a vehicle for transporting repair crews and supplies and embodies a pumping station, lighting plant, repair shop and a wireless equipment, enabling the workers to keep in constant touch with headquarters.

The wireless equipment, unlike any other portable set, enables the crew to receive messages while the truck is being driven along the streets. When ready for action it is capable of pumping 12,000 gallons of water per hour from a flooded conduit and it will furnish a flood of light for inspection and repairs, to say nothing of carrying all the necessary paraphernalia.

Truck Is Receiving Station Only

The most unusual and interesting feature of the outfit is the wireless equipment, through the agency of which the department keeps in constant communication with its trouble crew, so that all emergency calls can be handled with the greatest dispatch before serious damage can ensue. The truck serves as a receiving station only.

The antennæ are suspended immediately under the roof of the car and are made of approximately 425 feet of No. 14 stranded, rubber insulated, copper wire, which was laced back and forth until forty wires were obtained with a separation of 1 inch.

A series of rigid tests proved conclusively that the equipment is entirely practical and that excellent results can be obtained, through the aid of a simple code of signals without resorting to the employment of trained wireless operators. It was also demonstrated that direct earth connection was unnecessary, inasmuch as the iron framework of the chassis serves admirably as a counter-poise ground, thereby enabling the truck to receive while in motion.

During all the preliminary tests the truck never failed to intercept any message sent to it within a radius of 10 miles of the sending station, and even under the most unfavorable conditions, with the truck running at full speed and blanketed by tall buildings of steel construction, no difficulty was experienced in reading the messages.

The body is specially constructed. Hinged entrance doors, one on each side, greatly facilitate the operation of the equipment, while hinged double doors in the rear provide a ready access to various inclosed compartments used as repositories for suction hose and other paraphernalia. The overhanging hood also forms a locker compartment which is used for the storage of boots and water-proofing clothing.

12,000 Gallons-per-Hour Pump

Just in the rear of the driver's seat is mounted a gasoline-driven centrifugal pump which is capable of exhausting water from manholes at the rate of 12,000 gallons per hour. For the sake of economy the pump is not driven by the 30 horse-power truck engine, but is directly connected to an independent four horse-power gasoline marine engine.

The pumping engine, however, is cooled from the same source as the larger engine, that is, water is pumped from the bottom of the truck radiator through flexible metal hose to the marine engine and returned to the top of the radiator after circulating around the cylinders of the truck engine.

The pumping engine also operates a small dynamo, which, in addition to furnishing ignition for the marine engine, supplies sufficient current for illuminating manholes. By the aid of the portable lamps, which can be plugged in on the dynamo current, duct chambers may be examined for a distance of 50 feet to determine the nature and cause of obstructions in the conduits.

White truck in the service of the Electrical Commission of the City of Baltimore, which, in addition to performing manifold duties, is fitted with a wireless receiving station by means of which it keeps in constant communication with the office

Top and Upholstery Often Neglected

Many Car Owners Do Not Realize Value of Their Part in Appearance—Artificial Leather Improving in Quality and Gaining in Use—Carpets Important

By M. C. Hillick

THE last word in top and upholstering goods is probably Morocco, water grain, French finish, hand-buffed leather. This leather is to be had in either pebble or straight grain, and in all the popular colors, black, green, etc. The Morocco leather, finished as above, represents the most elegant and expensive class of trimming leathers used in automobile work.

Next to the Morocco is the hand-buffed Spanish leather likewise furnished in practically all colors. This Spanish material yields beautiful effects. These leathers may also be obtained in machine-buffed form, and while they may not suit the buyer of exacting inclinations they nevertheless are capable of wearing durably and show a finish concerning which even the expert has small reason to complain.

Buffed Leather, etc., Good

Specially buffed leather, split grades, and so on, are extensively employed in automobile top and upholstery work, and such leathers show an attractive form and finish, and stand up nicely under severe service at a moderate cost.

Black enamel top leather, either in pebble or straight grain, and in various grades is, in addition to the above, being put into automobile trimming.

In the making of leather substitutes there is no end. The popularity of these goods, in all conceivable colors and styles of finish, is a matter of comparatively recent history.

With the great middle class of car buyers these artificial leather fabrics are favorites because they furnish such a variety of style, color and design, at a reasonable expense, that all may enjoy them.

Artificial Leather Gains

The increasing demand for artificial leather is, moreover, due to the steadily decreasing supply of cattle hides the world over. The present year, it is stated by those having access to the statistics, imported hides have constituted fully 45 per cent. of the total amount of raw leather used in this country. Should the prevailing conditions in the hide market fail to mend in the near future we may reasonably expect to find the consumption of artificial leather enormously increasing.

When the production of artificial leather first became a noteworthy business the process consisted, in the main, of covering cloth with a flexible composition and then embossing the resultant product in imitation of leather.

Processes Are Improved

Improvement in manufacturing process has developed a fabric which today is suitable for tops, curtains, cushions—in fact, suitable for anything about the automobile that leather is suitable for.

The most essential feature, among many, of the artificial leather, is the coating, and for the splendid resources of this medium we have to thank the chemist. The requirements of the coating are manifold. In the first place it must retain its chemical composition without change throughout all its life. During the cold of winter and the heat of summer, it must retain a uniform suppleness and flexibility. It must have toughness of texture to allow for the mechanical manipulation and stretching necessary to shape it into the fashions designed by the trimmer. This coating composition must have adhesive properties of such power that, regardless of time or nature of service, it will not peel. Originally it was applied to coarse-woven fabrics, but heavy sateen is at the present time chiefly, or at least very largely, used as the backing up cloth, although, of course, it can be, and, in fact, is applied to many fine cloths.

Close Imitation Required

No great demand for the embossing of this artificial leather for top and curtain uses exists. However, for cushions and upholstery goods applied to the interior of the car there is a large market, and the call is for the closest possible imitation. That public requirements in this respect are being successfully met is attested by the fact that expert judges of leather sometimes mistake the artificial material for genuine leather. The remarkably real feel and appearance of the artificial leather is due in large part, it is said, to the exceedingly fine embossing plates produced through the medium of electrotyping processes from the genuine leather.

Carpets a Factor

Carpets constitute an important feature of automobile upholstery work. Not only should they harmonize in color and design with the other interior appointments of the car, but they should, moreover, accentuate and add to the general charm and luxury of the whole upholstering scheme.

The loosely woven, flimsy carpet that persists in creeping under one's feet is a poor investment. So, too, may we describe the carpet carrying an inferior dye that discolors and bleaches out. Insist on the carpet with a guaranteed fast dye.

Quality Most Important

Carpets are furnished in many colors, kinds, and qualities, among which you will find horse hair in mixtures fancy and plain, wools, worsteds, jutes, and so on; but whatever the sort or color, make quality, first of all, the basis of your choice. Then see that the fitting is correct, that the carpet is well made, and that in all respects it is a distinct addition to the artistic appearance of the car interior.

The closed type of car is showing many beautiful novelties in upholstering fabrics. Among the recently introduced novelties are such leaders as bedfords, Parisian and Vienna cloths, etc. In broadcloth the so-called Four-in-Hand fabric is probably one of the best known. It has quality, richness of effect, fineness of finish, and great durability, the latter a very telling factor in the case of a material that is expected to do service for more than a season or two.

Plain Cloths Popular

The popularity of plain cloths, broadcloth finish, is notably on the increase among exclusive users of the closed car. These cloths reflect a modest, but unmistakable elegance quite unsurpassed by other textile fabrics, and they continue to have this refinement of finish until well worn beyond the point of renovation or repair.

Foreign fabrics for use in the above class of cars are said to be superior in practically all points to those of domestic manufacture, and recent tariff reductions have brought these foreign made goods to the consumer in this country at no advance in cost over the domestic article. However, should the present European war long continue the "Made in America" goods must suffice. The domestic manufacturer, it would seem, has only to create novelties in design, increase their suitability to automobile requirements, improve their finish, and impart to them the required measure of durability, in order to occupy a preeminent position in this field of work.

Bad Garage Practices

In the care of the car top, trimming and upholstery furnishings, etc., the car owner may very well regard it as a matter to be vitally concerned with. Garage practices are too often ruinous to the reasonable wear and the original appearance of the fabrics employed. Leather, and good artificial leather materials will naturally stand much abuse without, for a time, showing evidences of brutal treatment. On the other hand, the upholstery and interior furnishings of the car reveal at once the lack of care, or the wrong kind of care, which the garage attendant or the chauffeur may be guilty of. Many of the fine upholstery fabrics, in cleaning, should be worked over with a brush; never with an ordinary whisk room.

Special Upholstery Brooms

There are soft point brooms now specially furnished for this work which readily remove light dust without injury to the cloth. The vacuum cleaner properly handled will extract all manner of dry dust and dirt from the upholstery and the car interior. Grease spots, oil smears, and stains of many kinds may be removed from the cloth upholstering by saturating a piece of the same goods as that contained in the upholstering with ether, and rubbing the cloth sharply over the smear or stain. If, for any reason, the strength of the ether needs to be reduced this may be accomplished by mixing it with pure grain alcohol. Ether mixes in all proportions with alcohol, either grain or denatured. It should be used with great care, however, being very inflammable and its heavy vapor is a source of much danger from fire. Nevertheless, as a simple, effective medium for extracting stains, grease spots, etc., from cloth goods, without injury to the finest fabrics, it is unexcelled, if applied as above directed.

In looking after the automobile top fabrics, the leathers, hand or machine buffed, so long as the enamel remains in good condition will need when mud splashed or stained with the accumulations of travel, scarcely more than wiping off with a soft wool sponge wet in a weak solution of castile soap and soft water. It is a good plan to defer the application of dressings, renovators, etc., until the wear of the goods makes these renewal mediums necessary. The same advice applies to the artificial leather products. For mohair, as has already been stated in these columns, the whisk broom deftly used furnishes the most dependable results. The use of benzine, gasoline, naphtha, alcohol, or any other solvent, for cleaning the mohair top should be strictly prohibited.

Apply Dressing Sparingly

In coating up the leather, rubber or artificial leather top, the never to be violated rule should read: "Apply sparingly." A little of such mediums may with profit to the car owner go a long way. At the same time, some good reliable dressing material becomes a necessity in due course.

Things Worth Saving

What the car owner and user needs to appreciate is the fact that the useful life of the car depends to an important extent upon the character and quality of the top, trimming and upholstery fabrics, and the manner of promoting their wear and appearance.

Haynes Cabriolet Is An All-Weather Car

BUILT to be equally useful in all sorts of weather, the Haynes six cabriolet may be used as a coupé completely inclosed, or, at a moment's notice, changed into an open roadster. The cabriolet mounted on the model 30 chassis sells for $1,750. The body comes in light royal green finish.

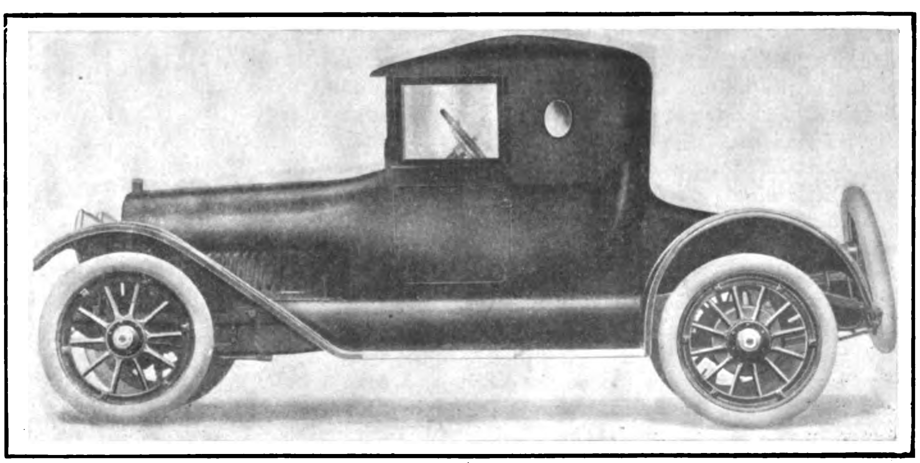
When used as a roadster the plate glass windows are dropped into recesses in the doors and the curtains are kept in a carrying space built into the back of the seat. The collapsible top is made of high grade black leather and is braced in such a manner as to stretch out all wrinkles when in the coupé position, giving a smooth, even appearance.

The transformation from roadster to coupé or vice versa may be effected in less than a minute's time by a person within the car.

The cushion is 46 inches wide and is unusually deep, and the car, although much lighter than any coupé, is remarkable for its Pullman-like riding qualities. A compartment is provided in the back of the driver's seat, out of the way and yet easily accessible, for carrying gloves, parcels and other small articles; and ample space is provided at the rear for carrying suitcases, grips, etc.

The upholstery is of the same grade black leather as the top and is deep and resilient.

A motor-driven tire pump, clear and rain vision ventilating windshield, Stewart-Warner speedometer, Firestone demountable rims, including extra spare rim, tire carrier at rear of chassis, electric horn located under the hood and operated from button at center of steering wheel, Leece-Neville electric starting and lighting separate unit system, large electric headlights with No-Glare bulbs and special dimming attachment, electric tail light, cowl light and dome lamp, 100-ampere hour storage battery, robe and foot rails, carpet on floor, and full set of tools are included in the regular equipment. A set of five Houk wire wheels is furnished for $100 extra.



New Haynes six cabriolet which, mounted on model 30 chassis, sells for $1,750

The Rostrum

Additional Treads Increase Gasoline Consumption

EDITOR THE AUTOMOBILE:—I have noted with interest the opinions expressed recently as regards the practicability of applying additional treads, or carcasses, of old shoes over casings in serviceable shape. I have not seen advanced any argument which is authoritative as to the economic principle involved and having had over 5 years' experience with tire damage and misuse and its origin, I have gained more than a fair knowledge of what is conducive and detrimental to tire longevity.

Tire resiliency is a most important factor, for the car mechanism, as well as the tires. Loss in this connection means increased gasoline consumption as the engine and its parts must function under more trying conditions. By applying an additional tread, it is most surely diminishing tire resiliency and I offer in substantiation the following examples:

Take five thin pieces of sheet metal, bend in the middle, continue a hinge-like action for several minutes. Now try a second experiment to obtain a comparison. Take ten pieces of metal similar to the above and repeat the action above mentioned. What do we find? Double the amount of energy required to produce the same degree of flexibility. A tire with an added tread is working under these latter conditions and as it must retain its normal speed, gasoline consumption is increased as well as wear and tear on the car mechanism. There is absolutely nothing illogical or theoretical in this comparison.

Second in importance is the heat occasioned by the additional opportunity for friction to develop. Under ordinary conditions there are several places for friction to occur. By adding a tread you will double this number and, therefore, increase the opportunity for development of this disastrous action. Canvas will give way from the inside first unless, provoked by an injury, and its durability under abnormal conditions will unquestionably be curtailed. Instead of increasing the number of plies of canvas in a shoe, such as one would be doing by the application of an additional tread, the tendency should be towards decreasing, as the ideal tire from an all-round standpoint would be one constructed of two plies, allowing only one place for friction to develop. The cord tire as manufactured in this country today is the achievement of this tendency and is found to be highly successful for the manufacturer and economical for the car owner. There are only two plies in the carcass of this tire regardless of its size and it is the strongest and most resilient tire in use today.

New York City. JOHN C. PEPPER.

Recommends Fabric Clutch Facing

Editor THE AUTOMOBILE:—I wish to say a word with reference to clutch facings, being prompted by reading your answer to J. F. Angstad in the issue of November 12. I have replaced a leather facing with one made of fabric such as is used for brake linings and have had no clutch trouble since. The fabric was bought endless and hence was applied very easily. I find that the fabric is better than leather for the reason that oil does not injure it—in fact it works better after a little oil is squirted upon the face. With the leather clutch both water and oil of a certain kind cause poor operation.

Another thing I have found, and that is that the fabric lining wears better and holds much better although at first I had trouble with grabbing due to poor adjustment of the clutch spring. I used the fabric lining because I heard that many racing cars had abandoned the leather. I read a letter in one of the trade magazines about a Duesenberg car, which I believe was equipped with Thermoid clutch facing. Then I tried the same and got very good results. One very important feature of the fabric, I think, which you do not mention is that it does not require the care that leather needs, and I believe the fabric is the most advanced form of clutch facing.

I would like to hear what other readers have done in the matter of clutch facing.

Chicago, Ill. J. McGOVERN.

Friction Drive Suitable for All Cars

Editor THE AUTOMOBILE:—I note that Mr. Frank A. Rice, Ithaca, N. Y., made inquiry as to whether there had been published in THE AUTOMOBILE an article on the advantages and disadvantages of the friction drive as compared with other types of transmission now more commonly used.

You state the disadvantages are that, "the friction disk must be renewed every few thousand miles. This is a small matter but worth noting." Permit us to state that since we have been using the copper alloy disk which we have now for over 4 years, that we have yet to renew a single one and we could show you many of them which have been run as high as 100,000 miles, and show practically no wear. The average life of the friction filler is all the way from 5,000 to 20,000 miles and costs but $5.00 to replace, at retail.

You further state that the amount of horsepower that it will transmit under the conditions found in automobile design is limited, therefore, has never been used to any extent on large cars but has found favor on some cars of medium size and on more small ones. The friction transmission is just as successful in a large high-power car as on a small one. It is simply a case of building the transmission to take care of the power. One of the most successful models we ever built was a seven-passenger car having a four-cylinder motor, 4.5 by 5.25 car weighing 4,000 pounds.

Pontiac, Mich. H. R. RADFORD, Gen. Mgr. Cartercar Co.

—The statement referring to the life of the disk was slightly in error. The fiber filler in the rim of the friction wheel was the part referred to but inadvertently the word disk was used instead of the word wheel.

Three Types of Radiator Construction

Editor THE AUTOMOBILE:—What are the different types of radiator construction? Illustrate them.

2—Where could I obtain the best book for the care and repair of storage batteries, principally those used for cranking and ignition systems?

Rices Landing, Pa. A. J. SHARPNACK.

—1—There are three principal types of radiator construction, the cellular, vertical tubular and horizontal tubular. These are illustrated in Fig. 1. There are many variations under the first head. The second and third types are generally provided with fins to increase the effectiveness of the cooling.

The best example of the cellular radiator is the true honeycomb which was introduced by the Mercedes company. This is shown in Fig. 2. There are both horizontal and vertical passages in this design. There are many types that resemble this closely in principle, the only difference being in the section of the individual tube through which the air flows. One of these is illustrated in Fig. 3.

There are many radiators that look like the honeycomb, yet are not, being more like vertical tube radiators. Two of these are shown in Fig. 4. Still another type of cellular radiator is shown in Fig. 5. This is a combination of the vertical and horizontal flow designs.

2—The Electric Vehicle Hand-Book, by H. C. Cushing, Jr., and Frank W. Smith, published by H. C. Cushing, Jr., 53 Park Row, and Manual of Exide Batteries in Electric Vehicles, published by the Electric Storage Battery Co., Philadelphia, Pa., are two good books.

Operation of Electric Furnace

Editor THE AUTOMOBILE:—Can electricity be used in any way to heat a furnace, or furnish heat? If so, how? Give instances.

2—What machinery is necessary for charging storage batteries?

3—What are the objections and advantages of the friction transmission?

4—What is the price of the 1914 Cartercar?

5—What company makes the frictions used in the transmissions of this car?

6—How many Cartercar cars are in use?

7—How long has the Cartercar been manufactured?

Cooper, N. C. S. B. TEW.

—1—Whenever an electric current flows it gives off heat. The amount produced when the current flows through an ordinary wire is small because the conductor, which is generally copper, has a low resistance and therefore does not heat to any extent under the transmission of normal current but if an excessive current flows, the wire may melt. In other words the amount of heating depends on the resistance the wire offers to the flow of current, and the amount of current flowing. The resistance varies with different materials, copper and silver offering the least resistance, and also with the size of the wire. A wire with a cross-sectional area of .1 square inch will offer twice the resistance of a wire of the same material but with half the area.

Electric furnaces may be divided into two classes. Those in which the heating effect is produced by the electric arc between the electrodes which are generally made of carbon—in the spark plug, which is an electric furnace on a small scale, the electrodes are metal, and those in which the heat is produced by the passage of the current through a resistance which either forms part of the furnace proper or else is the material which is to be treated.

In the Moissan arc furnace two chalk blocks are bored out to receive a carbon crucible which incloses the center or hearth of the furnace proper. In this cavity pass two massive carbon electrodes, through openings in the walls which are held together by clamps. The arc established between the ends of the carbons when the current is turned on, plays over the center of the crucible, heating the contents.

The other type of furnace which is known as a resistance furnace may be illustrated by the Acheson furnace which is used for the manufacture of carborundum.

It is a rough firebrick structure, through the end walls of which project the electrodes consisting of composite bundles of carbon rods set in metal clamps. The space between the two electrodes is bridged by a conducting path of

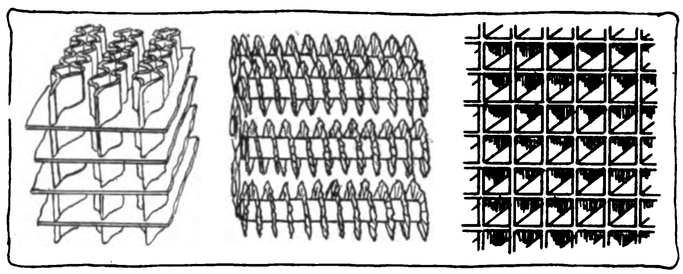

Fig. 1—Three principal types of radiator construction. At the left is the vertical tubular, in the center the horizontal tubular and at the right is the cellular

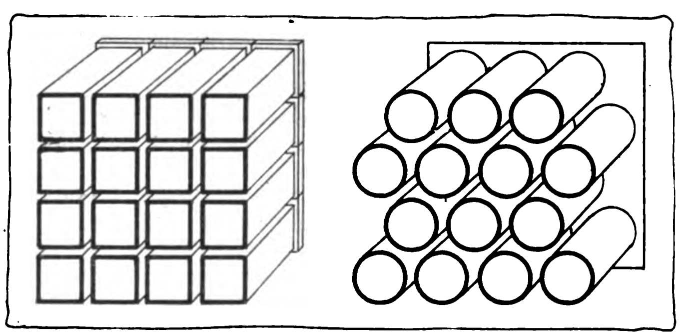

Fig. 2—Left—True honeycomb radiator. Fig. 3—Right—Radiator resembling Mercedes somewhat in principle

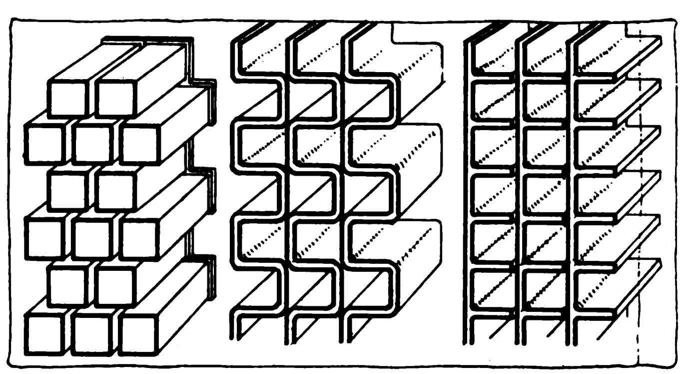

Fig. 4—Right and Center—Cellular radiators which appear to be honeycomb. Fig. 5—Left—Another cellular type

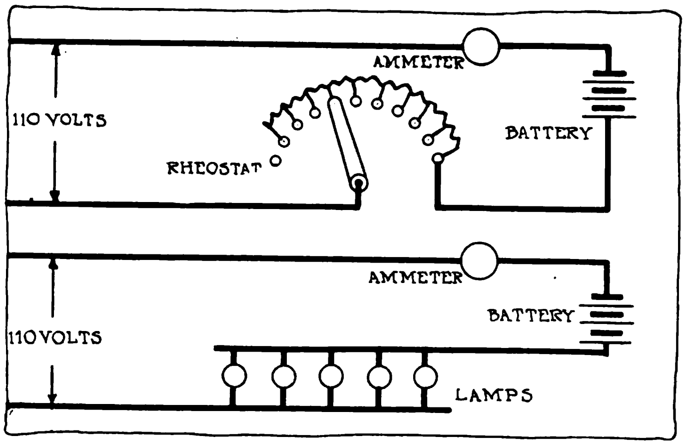

Fig. 6—Upper shows wiring diagram for charging a storage battery from direct current by the use of a rheostat. Fig. 7—The lower illustrates the use of a lamp board resistance in place of the rheostat. The resistance is varied by screwing lamps in or out

coke, which constitutes the core of the furnace. This coke is packed around with the raw material, consisting of coke, sand, sawdust and common salt.

2—The apparatus required for charging a storage battery depends on whether the current available is alternating or direct. If the latter, all that is required is an ammeter, some form of variable resistance to vary the rate of current flow, the necessary switches and wiring, and a hydrometer. If the former, a rectifier will be required to turn the current into direct, as it is obviously impossible to charge a battery with alternating current.

Fig. 6 shows the method of connecting a battery for charging on direct current. The positive of the charging line should be connected to the positive side of the battery. The rheostat is for the purpose of controlling the flow of current through the battery.

A lamp board, Fig. 7, may be used instead of the rheostat. Every lamp in circuit means decreased resistance, and increased current flow. If 110-volt lamps of 16 candlepower and carbon filaments are used, each lamp in circuit allows the passage of about .5 ampere, therefore if the charging rate were 5 amperes, ten lamps would be needed.

3—See The Rostrum for November 5 and this issue, page 1026.

4—The price of the 1914 model is $1,250.

5—Rockwood Mfg. Co., Indianapolis, Ind.

6—There are about 10,000 according to the Cartercar company.

7—The Cartercar has been actively produced since 1906, although a few cars were turned out before this time.

Gasoline Consumption High

Editor THE AUTOMOBILE:—1—I have a 1912 model 40-horsepower Michigan automobile and would like to know if it would be advisable to put radius rods and an additional torque tube on same.

2—What company made the above car, and why was it discontinued?

3—What would you suggest to lower my gas consumption? The car is equipped with a Stromberg with hot-air pipe. I have tried every possible adjustment on the carbureter with no satisfactory results.

4—About how many miles per gallon of gasoline should I get? The compression is very good and the engine runs nicely on high and low speeds.

5—What did the above car cost new? It is a five-passenger 40-horsepower, and was the car made entirely in the Michigan shops?

Brigham City, Utah. A READER.

—1—Unless you are certain that fitting a torque rod and radius rods will improve the running of the car do not do it. You do not state why you desire to make this change. If you are having trouble with spring leaves breaking, it would be better to install new leaves or complete springs, as required. This car was designed to operate properly without the use of torque or radius rods, and therefore it is likely that it will give satisfaction without the addition of these members, providing defects are corrected.

It would be difficult, if not impossible, to fit radius and torque rods so that they will work properly.

2—The Michigan Buggy Co. made this car. The company failed.

3—How do you know the carbureter is at fault? Possibly you are driving with too late a spark. Keep the spark lever advanced as far as possible at all times without allowing the motor to knock. Jack up the front wheels and note whether they turn freely. Do the same with the rear wheels with the gear lever in neutral. If any great resistance is encountered in turning the wheels, look at the bearings and also note whether the brakes are dragging. Then repeat this part of the test with the lever in gear and the clutch out. If the system turns hard there must be excessive friction in the gearset.

Make certain that you are receiving full measure when you buy your fuel and that there are no leaks in the system.

4 and 5—This information is unobtainable.

Starting on Cold Mornings

Editor THE AUTOMOBILE:—I am the owner of an Overland roadster, 1914 model, and since the cold weather has come I have experienced a little difficulty in starting in the mornings. Would it be any benefit to double the number of dry batteries so that the additional number could be switched on and off at the moments of starting? In other words, would increasing the number of dry batteries approximate a high-tension magneto and again, would increasing the number of batteries injure the coil?

Lansford, Pa. L. DOUNELLY.

—No. This would injure the coil by allowing an excessive current to flow through it. If your present cells are in good condition, they should furnish a satisfactory spark for easy starting.

The spark is probably all right but the real difficulty is due to the gasoline not vaporizing. To overcome this trouble you might use a lighter grade of gasoline, such as you can probably obtain at your drug store. Ether might also be used. Either of these fuels may be injected through the priming cups or introduced through a special priming device.

There are several devices on the market which facilitate starting on cold mornings by warming the fuel; one of these might be a good remedy for your trouble. You might also use a radiator heater to keep the motor warm at night.

Mitchell Six Motor Information

Editor THE AUTOMOBILE:—1—Who manufactures the motor that is used in the 1914 Mitchell Big-Six 4 1-4 by 7?

2—At what speed does it give its best results?

3—What is the highest speed obtained by these motors?

4—What timing should be used for speed?

5—Would the intake valves stand more than one tooth advance from its present timing? Would exhaust?

6—What is the maximum speed of the Wisconsin model K motor?

7—What ratio of weight is used in determining the weight of the crankshaft to the connecting-rods and pistons? Also the flywheel to the other masses?

8—Are the steel cylinders, like those used in De Palma's Mercedes, a difficult engineering problem, and are they very expensive castings to make?

9—What percentage of steel is used in the pistons in the racing Delages?

10—What gear ratio would be best on a 1914 Trumbull?
Manchester, N. H. R. & L.

—1—This is built completely in the Mitchell plant.

2—It gives a maximum of 72.7 horsepower at 1,300 revolutions per minute.

3—The maximum speed is 2,000 revolutions per minute.

4—Use the regular timing. If maximum speed is desired the ratio of the bevel gears should be changed from 3.357 to 2.936 to 1.

5—The timing of the intake and exhaust can be very easily advanced if so desired, although it is doubtful whether an increase of power will be noted.

6—The type K motor which is a six-cylinder, T-head design, 5.25 by 7 inches, with the cylinders cast in pairs develops about 112 horsepower at 1,400 revolutions per minute. This motor is also built as a racing design known as the KR. This model will give 175 horsepower at 2,000 revolutions per minute, it is stated.

7—There is no definite relation between the weight of the connecting-rods and the crankshaft. The crankshaft must be stiff enough to stand the stresses imposed upon it not only without breaking but without deflecting sufficiently to cause uneven wear on the bearings. Likewise the connecting-rods must be strong enough to take the piston loads without giving out.

The size of flywheel depends on the speed of the motor. A very high-speed motor that is not expected to throttle down can have a very small flywheel. Some such motors have been built with none at all.

The function of the flywheel is merely to store energy. Part of the explosive force of each power stroke is stored in it by accelerating it slightly. This energy is drawn from the flywheel later, the flywheel slowing down a small amount. On a high-speed, racing motor the impulses come so close together that there is little need to store energy for use between the power impulses.

8—The cylinders used on De Palma's latest Mercedes were very costly to make, since they were machined from individual blocks of steel.

9—The composition of these pistons is not known.

10—The stock gear ratio is probably best. In a very hilly country a somewhat lower gear might be found better, and on the other hand in a very level country, a higher gear might be more satisfactory. You must use your own judgment in this matter.

Wood Alcohol—a Good Carbon Remover

Editor THE AUTOMOBILE:—Please advise me whether you recommend the use of wood alcohol as anti-carbon treatment.

I used it twice, when the motor was very hot, using about 4 ounces per cylinder. When the car was started the next day, it smoked, had an alcohol smell but seems to run better. In my opinion it is superior to kerosene.

2—Are 4 ounces too much?

3—Does it injure any part of the motor or does it affect the oil in the base?

4—What temperature will half wood alcohol and half water stand safely in a radiator during the winter?

Fall River, Mass. E. J. D.

—1—Wood alcohol should be satisfactory. Four ounces should be enough for each cylinder. After injection of the liquid to all cylinders the motor should be cranked a few times to distribute the alcohol to all parts of the combustion chambers.

2—No.

3—No. Alcohol has no action on metals nor on lubricating oil. The only effect it would have would be to dilute the oil in the crankcase, but the alcohol in this oil would soon evaporate.

4—Thirty degrees below zero Fahrenheit. This subject was fully discussed in the Rostrum for October 15.

To Go from Los Angeles to Chicago

Editor THE AUTOMOBILE:—Can you refer me to any pamphlet or article describing a trip from Santa Fé or Los Angeles across to Chicago? Am principally interested in finding out the best summer route and condition of roads from the coast through to Omaha.

Three Rivers, Mich. CHAS. P. WHEELER.

—According to the *Automobile Blue Book* there are two main routes, Fig. 8, both of which are good in summer. One is by way of Salt Lake City and the other through Santa Fé.

The former is not practicable before April 15, but the latter is open all year.

Starting from Los Angeles over the Northern route go through San Francisco, Sacramento, Reno, Winemucca, to Ogden, thence through Cheyenne, to Omaha. The Southern route lies through Needles, Flagstaff, Springerville, Santa Fé, La Juanita, Hutchinson, Kansas City, St. Joseph, Omaha. An alternative route through from Los Angeles is by way of San Diego, Yuma, Phoenix, Springerville. The parts of the road which are indicated by the full black line are good. The Northern route follows the Lincoln Highway from Salt Lake City to Omaha. From Omaha, go to Chicago by way of Des Moines and Clinton.

Fan Flywheel Requires Small Clutch

Editor THE AUTOMOBILE:—Would you kindly explain why the fan for cooling is not made integral with the flywheel on cars having the transmission combined with the rear axles?

During the last 3 years I have driven a car having the fan integral with the flywheel and have not found anything wrong with the cooling system.

2—Was this system of cooling used on Mercedes cars? If so, to what extent?

Cleveland, O. T. J. MILLER.

—1—First of all the flywheel type of fan does not produce as rapid a circulation of air as the ordinary type just behind the radiator. Second, even with the gearset on the rear axle it might not be possible to use a fan flywheel. This type of flywheel, when at the rear, requires that the clutch be very small, in other words a multiple-disk clutch of small diameter or a clutch of the original Mercedes type must be used. A cone clutch, expanding band or large-diameter, dry-plate can not be used.

In other words less is required of the radiator. It may be smaller, the water circulation and pump speed slower or a less effective radiator may be used.

2—This method of air circulation has always been used on Mercedes cars.

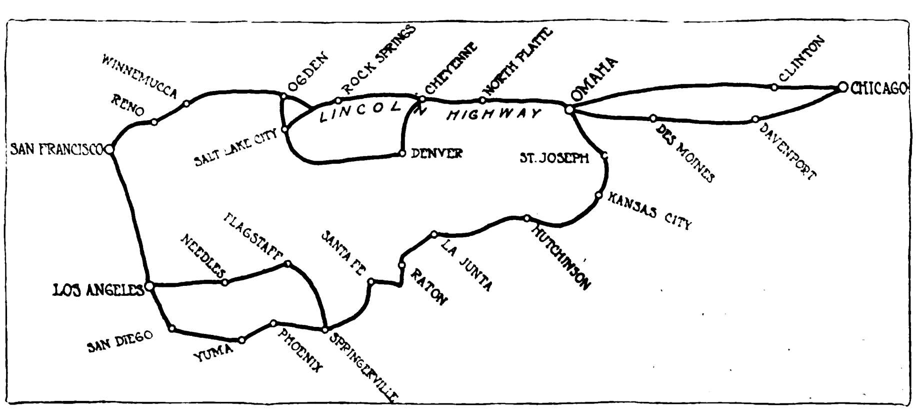

Fig. 8—Map showing best routes between Los Angeles and Chicago

Trucks and the Traffic Engineer

Motor Truck Is a Hauling Machine Built to Compete with the Horse-Drawn Vehicle and to Be Sold to Business Men as an Investment

THE traffic engineer is the efficiency doctor of motor truck selling, and motor truck operating. A motor truck is a machine designed and built in a variety of sizes for hauling materials, its chief competitor being the horse-drawn vehicle. The motor truck has a high first cost and is bought by business men as an investment.

The Sales Problem

Now here you have the entire sales problem boiled down into one statement. A motor truck is a hauling machine which is to compete with the horse-drawn vehicle, and which is to be sold to business men as an investment.

Handling the Customer

We know the sales problem—how are we going to solve it?

The first step in selling any machine to a business man is to reach him and interest him. How is this to be done? It can be done in two ways:

First.—By proper advertising.

Second.—By supplying dealers and their salesmen with reliable, accurate, and undisputable data, carefully collected from all the various lines of business which the truck is designed to fit.

Real Advertising

By proper advertising is not meant advertising the chemical properties of your springs and axles for the horsepower, bore and stroke of the motor, but it means advertising the service value of the truck and the economies to be affected by its installation.

Here is where the traffic department must start. It must collect the data which should form a basis for all advertising and furnish the dealer and his salesmen with the ammunition which should not only interest the prospective buyer but make him ask for an investigation of his own delivery equipment.

Trucks Are Profitable

After we have reached and interested a customer what is the next step in selling a machine? The next step naturally is to show him that it will be a profitable investment for him to buy. This can only be accomplished after the salesman knows such facts as:

What is the present equipment doing?

What does it cost to operate and maintain it?

Editor's Note—At the recent convention of motor truck makers and dealers held in Detroit, Mich., by the Motor Truck Club of America, the question of traffic engineering was one of the most pertinent topics. One of the best suggestions on traffic engineering was that of having each truck company open a school on traffic engineering for the benefit of its dealers and their salesmen. The school would partake of a series of correspondence courses between the factory and the dealer, and the dealer in turn could use whatever means he desired for getting the information to his sales force. This plan was suggested by E. L. Shumacher, traffic engineer of the Denby Motor Truck Co., Detroit, Mich.

Can it be improved in any way?

What can the motor truck do operating under these conditions?

What will it cost to operate and maintain trucks working under these conditions?

The Salesman Expert

Such facts can only be learned after a thorough investigation has been made. A very large percentage of firms think they know what their delivery equipment is doing and what it costs, but actually a very small percentage knows, hence a motor truck salesman must be a transportation man, capable of analyzing conditions, comparing costs, accurately figuring savings and correctly advising the proper installations. In other words he must fit trucks to the business and not permit the business to be fitted to the truck.

Business Methods Needed

Merely going into a prospective customer and telling him he can replace three teams with one truck and save money because one of his competitors did so, is ridiculous and won't serve much longer. Why I have recently investigated two similar lines of business and found the cost per mile of operating the same kind of wagons doing the same class of work to vary over 100 per cent.

It is suicidal to the truck industry to sell trucks predicting savings on this information. The conditions under which deliveries are made, the efficiency of operating the equipment all vary so widely that it is impossible to accurately compare costs, calculate savings, or advise installation without a thorough investigation. And eventually the truck salesmen must be able to make these investigations for it is only after such investigations that business men can be shown that a motor truck is a profitable investment.

Know Your Truck

After the average business man has been interested in a machine and convinced that it will be a good investment there is still one point he must be convinced of. He must be convinced there is no better machine on the market from the standpoint of price, adaptability and economy.

Here again it is up to the salesman and he must know his product. This does not mean he must talk transmission, magneto or wheels, but it does mean that the buyer must be convinced that the cost per mile of operating and maintaining the proposed truck will be a minimum and that it will be the proper capacity and design for his particular requirements.

Competent Salesmen

This is nothing new in selling machines. I don't believe there is one type of machine excepting the motor truck which is not sold as just described. Take for example the gas producer, steam engine, locomotive machine tool, before any one of them can be sold the purchaser must be shown:

1—That he needs one.

2—That it will be a profitable investment.

3—There is no more profitable machine on the market.

Can you imagine a salesman selling steam engines without being so schooled in his product that he could not figure the cost per b.h.p. or the saving to be effected by replacing an older or less efficient equipment?

Can you imagine a gas producer salesman unable to accurately predict the quantity and B.t.u. value of the gas produced together with the savings it should effect over the installations?

Can you imagine tool salesmen unable to predict the advantages and exact performances of his milling machines or lathes? And the savings to be effected by this installation?

And likewise in the near future you will be unable to imagine a motor truck salesman unschooled in transportation analysis, costs and economies. Furthermore there is not one of the above named machines which is not sold along the same lines as trucks are being sold.

Now you will say, "What is it going to cost to sell trucks, under this plan?" and in answer, I will say, "the selling expense per car will be less, and the number of sales should very quickly double and treble."

You will then most probably ask, "Where are we to get salesmen capable of making these investigations, etc.?" and in answer I will say here is where the traffic engineering department comes in again. It does not take any more intelligent or higher grade salesman.

With a little schooling and coaching your present salesmen can all be supplied with the proper data and training and shown how easily they can make these investigations, and it should be one of the most important duties of the traffic department to help in this development.

Fooling Yourself

There is one other point in connection with motor truck selling which I wish to touch upon and that is "fooling the customer." Motor truck salesmen must realize that it is the truck buyer and not the manufacturer who pays their bills. Just as soon as they realize this they will have the backbone to advise him not to buy if it will be unprofitable, and the foresight to see that a sale made which will not be satisfactory to the customer will most probably spoil the chances for making a dozen or more similar sales, for one dissatisfied owner will do more harm to future business than a dozen satisfied owners can do good.

With the exception of motor truck selling I believe that motor truck operating offers the greatest field for advancing the motor truck industry quickly. This advancement will be made along three distinct lines:

1—By waging an educational campaign for truck owners and operators. This is being done at the present time by getting the truck owners and operators together once a month. At these meetings there is generally a couple of educational papers presented and the operators exchange their experiences and get light on their troubles.

2—By injecting efficiency into delivery equipments and methods. Deliveries have been considered necessary evils and have been run in a haphazard way. Very few are run economically. In some cases little things such as changing routings, or lengthening loading platforms will save considerable time and money. The salesman when making his investigation should be quick to detect such defects. There is no quicker or better way of convincing a firm that you know hauling problems.

3—By the development of time saving appliances such as quick loading and unloading devices, specially designed bodies, etc. It is in this direction and not in motor truck design that the opportunity for effecting large savings is offered. There undoubtedly will be many thousands of dollars saved in this direction.

This work naturally is one of the chief duties of the traffic engineering department and should do much in advancing the economies to be effected in motor truck operation.

Three Ideas

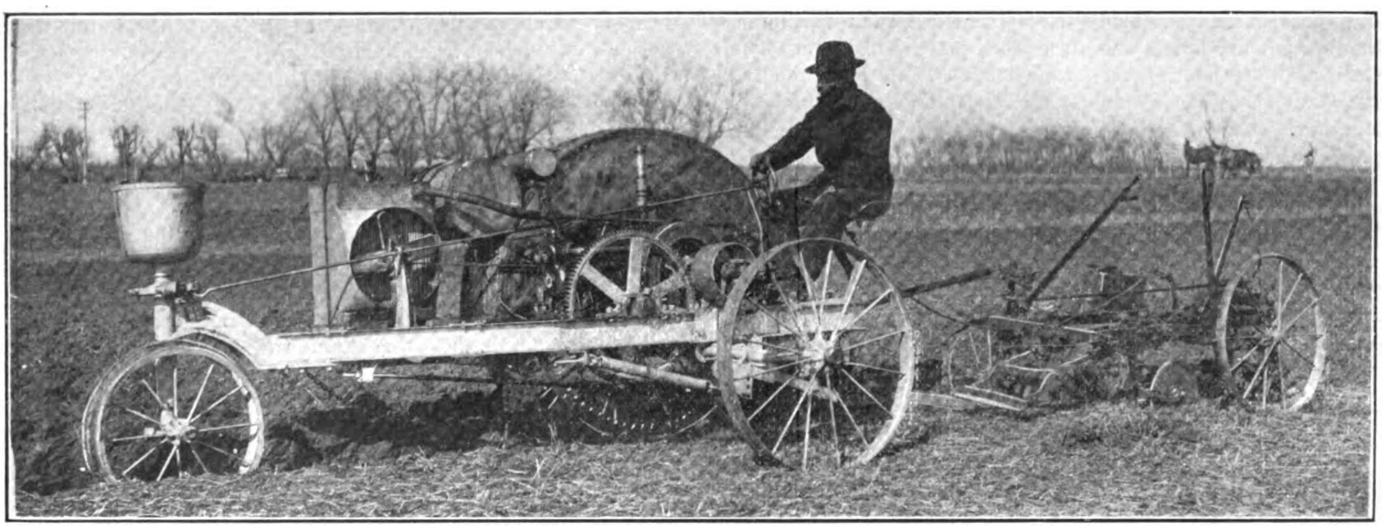
In conclusion I would simply like to add that any traffic engineering department if it ever expects to be a success or accomplish results, must bear in mind three things:

1—That every truck owner must be a satisfied owner.

2—That every dealer must make money.

3—That to accomplish 1 and 2 the traffic department and the dealer must work hand in hand to not only sell more trucks but to also sell them better.

Bull $335 Farm Tractor Does Work of Five Horses

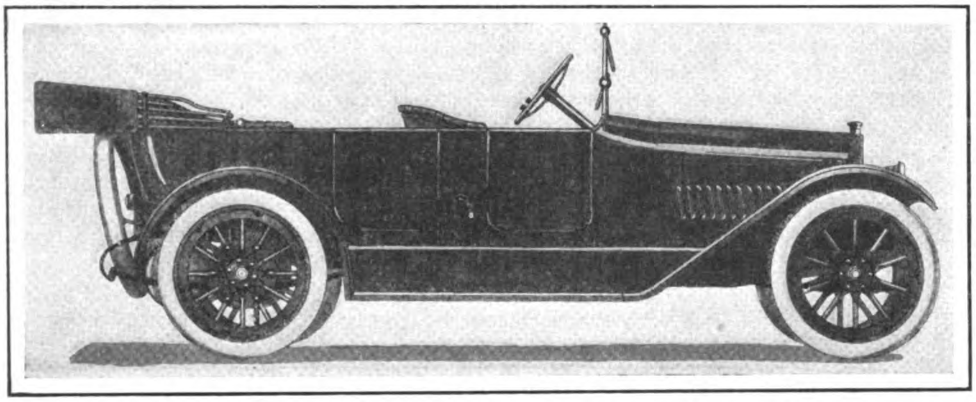


THE Bull Tractor Co., of Minneapolis, Minn., is manufacturing a farm tractor for $335 that is capable of pulling two 14-inch stubble plows or their equivalent in any other work on the farm. The tractor, which is shown in the accompanying illustration at work with a plow, employs a two-cylinder, four-cycle opposed motor having a bore of 4.75 and a stroke of 6.5 inches. It operates at from 750 to 800 revolutions per minute and delivers 5 horsepower to the draw-bar and 12 horsepower at the belt. It is 12 feet overall, 5 feet 4 inches high and 6 feet 6 inches wide. It operates on gasoline or Motor Spirit and the makers claim for it an average fuel consumption of 1.75 gallons per acre.

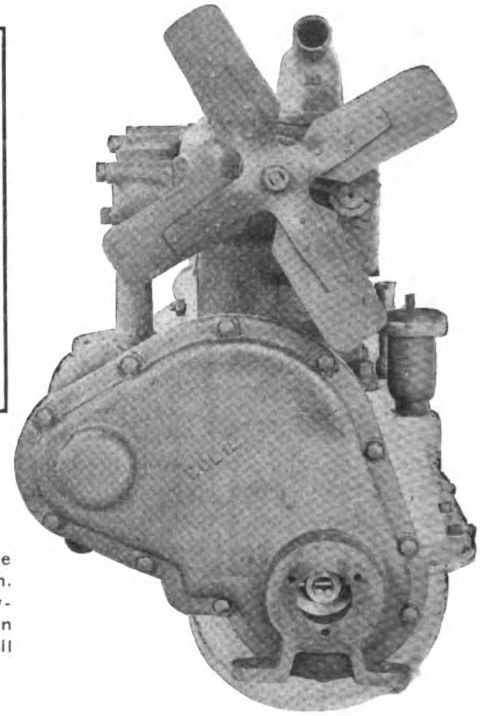
The Bull Tractor Co., estimates that the tractor is able to do the work of five good horses and for that reason represents a considerable saving of money to the farmer employing it. It is operated by one man who is seated on it and who guides it by means of the 28 inch front wheel which serves the double purpose of supporting the frame and at the same time automatically following the furrow for guidance in plowing. In other work it steers the same as an automobile.

CHICAGO, ILL., Nov. 27—The Illinois Public Utilities Commission has granted a license to the Chicago Automobile Transportation Co. which will launch Chicago's first boulevard motor bus line. The company expects to operate 150 cars. Four other motor bus companies have applied to the commission for licenses.

Kline Adopts Unit Power Plant



Touring body fitted to the six-cylinder Kline car for the 1915 season



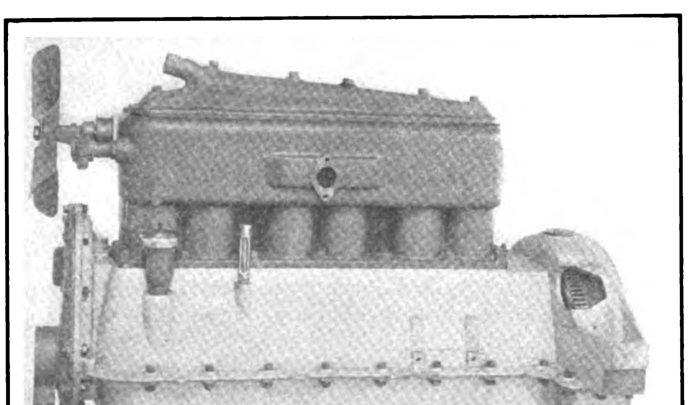
Front end of the new 3.5 by 5.125-in. power plant, showing mounting of fan and crankcase oil filler

Five Bodies on Two Chassis Similar Except Wheelbase—Change to Three Speeds

TWO chassis which are practically the same in every detail with the exception of the wheelbase will compose the line of the Kline Motor Car Corp., Richmond, Va., for the coming season. These chassis which are known respectively as 6-42 and 6-42A embody a six-cylinder motor which differs from previous Kline practice in that it is a unit power plant instead of the separate engine and amidship gearset as previously used. The cylinder castings on the new car are now a one-piece block instead of the separable block as in former practice. Last year Kline cars had their cylinders cast in pairs with the ends machined and bolted together.

New L-Head Motor

The new motor is an L-head which is not altogether new for the company as in a four previously manufactured it was employed, although the T-head has been used on the previous larger models. The three-point suspension heretofore employed has been changed. The pivot point was formerly at the flywheel but has now been changed to the front on account of the change to the unit power plant. The radiator suspension has been changed from the main side members to studs placed in the bottom of the radiator and bolted to a cross-member. This change was made on account of relieving the strain on the radiator, due to the twisting of the side members. In practice the company has found that the new suspension works out better as regards the elimination of strains on the radiator structure.



Left side of the six-cylinder L-head Kline motor

The four-speed gearset formerly used, which was direct on third and geared up on fourth, has been replaced by a three-speed type. The reasons advanced for this change is that the new motor is more flexible and more powerful than the old and the direct drive on high is quieter than the overgeared drive. It has been found, according to the company's engineer, that a speed of from 3 to 58 miles per hour can be obtained with the regular gear ratio of 3.75 to 1.

The electric starting motor has been changed to the left side of the engine above the frame line and bolted directly to the crankcase. This change has enabled the designers to completely inclose the Bendix gear by means of which engagement with the flywheel is effected, providing a more dirt-proof construction and at the same time silencing the engagement. The former mounting was on the right side of the motor below the line of connection to the frame and in muddy weather it was found difficult to keep the dirt from entering between the pinion and the teeth on the flywheel.

The lighting generator is now located on the right, next to the water pump, and is driven by the pump-shaft at 1.5 crankshaft speed. The former mounting was on the frame next to the gearbox and a silent chain drive was taken from a gear from the rear end of the gearset shaft. The generator has been decreased in speed by the difference in ratio of the former 3 to 1 and the new 1.5 to 1.

Vacuum Fuel Feed

A change in the gasoline system has been effected by placing the 20-gallon tank at the rear of the chassis and feeding by means of the Stewart-Vacuum system which carries the gasoline from the rear tank to a small tank on the side of the dash next to the motor and from there to the carbureter by gravity. Formerly there was a gasoline tank under the seat and a gravity system was used. By the new system it has been possible to shorten the intake manifold, which has resulted in more advantageous carburetion and a more accessible carbureter. There is a gain by this of 3 gallons in the capacity of the gasoline tank.

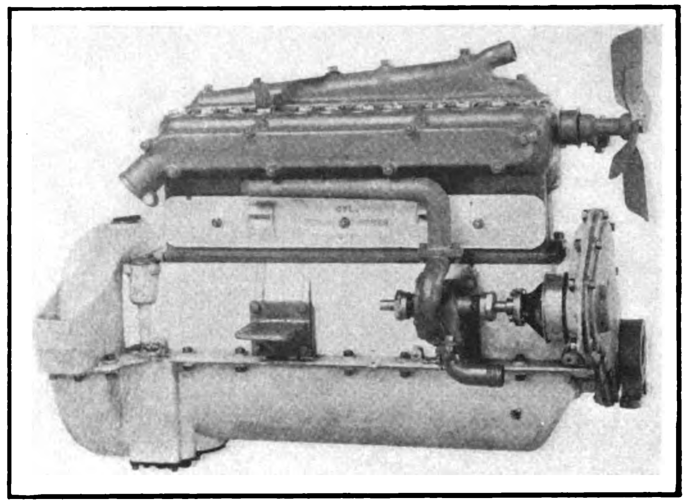
12 Per Cent. Lighter

A streamline body completes the list of innovations for the Kline car of 1915. It has a rounded radiator and hood, oval mud guards, built-in windshield, low, long body lines, deep upholstery and an up-to-date appearance throughout. The weight has been decreased more than 12 per cent. according to the Kline company, by using the unit power plant construction eliminating the sodpan, lighter body, top, rims, tire irons, etc., and by the fitting of narrower drip-pans between the motor base and frame.

The cylinders are 3.5 by 5.125 inches and have the valves on the right. The manifolds are formed with the intake integral with the cylinder casting and the exhaust separate. Cooling is accomplished by a centrifugal pump which circulates the water through ample water jackets and a cellular radiator.

Lubrication is taken care of by a combination pressure and splash system. The oil is forced by pump to the main bearings and thence flows to the splash trough, whence it is splashed to the cylinders and other bearings within the motor.

The entire electric equipment with the exception of the storage battery is taken care of by the Westinghouse company. The battery is a Willard. The system works at 6 volts and provides a dual-ignition system together with lighting and starting. The battery capacity is 130 ampere-hours at 6 volts.



Right side of Kline six-cylinder power plant

The clutch is a dry disk located in the flywheel with the driving surfaces engaging against asbestos and copper lining. The power is delivered to a three-speed gearbox which on direct provides a reduction of 3.75 to 1. Final drive is by spiral bevel and propulsion is through the springs. The rear axle is three-quarter floating. Thirty-four by 4 tires and a 123-inch wheelbase are found on the 6-42 chassis upon which are mounted a touring, toy tonneau or roadster body, while on the 6-42A chassis the wheelbase is 127 inches, the tires are 35 by 4 1-2 and the bodies are a seven-passenger touring and a seven-passenger limousine. The prices of the bodies on the 6-42 are $1,750. On the 6-42A, the touring is $1,850 and the limousine $2,850.

Completeness Features Moline-Knight Closed Cars

COMPLETENESS and luxury are the keynotes of the two closed cars recently brought out by the Moline Automobile Co., Inc., East Moline, Ill. They are a seven-passenger limousine and a five-passenger sedan mounted on the 50-horsepower Moline-Knight chassis. Three speed gearbox is standard, though a four-speed type may be furnished. Wheelbase is 128 inches for both cars and 36 by 4 1-2-inch tires are used. The limousine sells for $3,800 fully equipped and the sedan for $3,250 with wood wheels and for $3,340 with wire wheels.

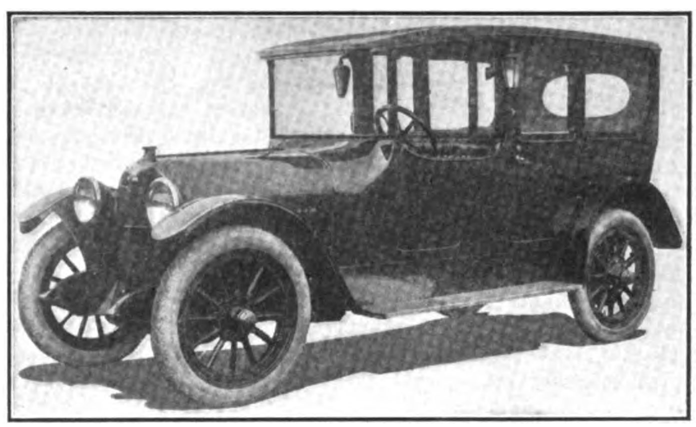
The tonneau of the limousine is trimmed with medium gray whipcord while the front seats are finished with hand buffed, long grain, black enamel leather. The body is painted blue above the panels and black beneath.

The window ledges are finished with aluminum drip molding and there are aluminum door moldings and nickel fence rails. The roof is three-ply veneered wood and the top over the driver's seat is painted black. The rear doors are hung with concealed upper hinges and the lower hinges are exposed covered joint types. The front door hinges are concealed. Equipment is complete.

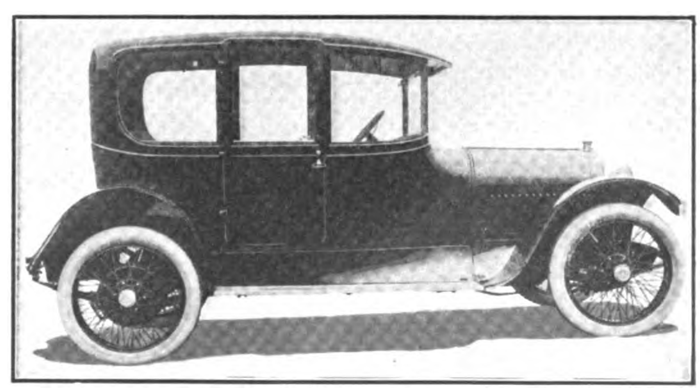
Removable auxiliary seats face forward and are arranged so that they may be folded against the side of the body or placed in sockets on the division when not in use.

Doors and windows are prevented from rattling by bumpers or antirattlers, and a pair of pillar lamps are so arranged that the light will be thrown on the running board.

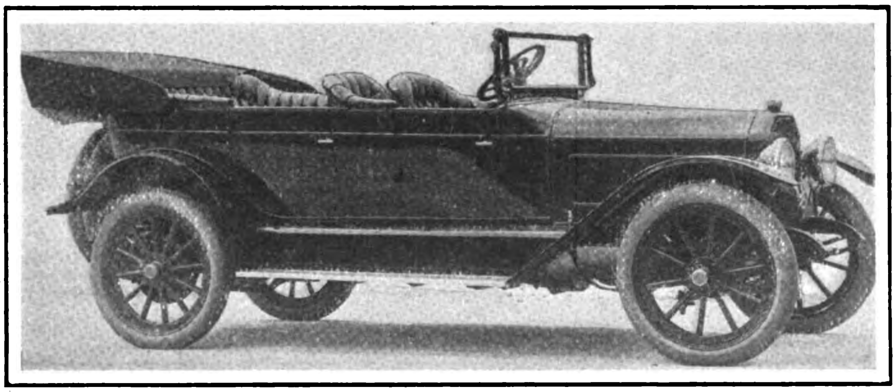
The general make-up of the sedan is similar to that of the limousine. A dark gray whipcord upholstering is used in place of the lighter gray in the limousine. All panels are of 22 gauge cold rolled automobile body steel with joints either welded or covered with aluminum molding. Equipment is similar to that of the limousine.



Moline-Knight limousine, which sells, completely equipped, for $3,800



Sedan at $3 250, with wood wheels, and at $3,340, with wire wheels



Five-passenger, six-cylinder Peerless touring car with individual front seats and selling for $2,250

New Peerless Four, $2,000—Six at $2,250

Block-Cast Unit Power Plants of Similar Design and Largely Similar Dimensions Used in Both Models

IN bringing out its two lighter and lower-priced cars, which have been styled all-purpose models, the Peerless Motor Car Co., Cleveland, O., has produced a type of machine new to its factory. Heretofore only big cars of the $5,000 and $6,000 class have borne the Peerless name, and the striking part of the move is that the new models 54 and 55, the latter a six, are none the less distinctive in appearance and finish or carefully designed than are the larger cars on the 48-six chassis. In the open models, the new four sells for $2,000, and the six for $2,250.

Block Cast Unit Power Plants

The motors, with the same dimensions wherever possible, are consistently alike in construction. They are block-cast unit power plants with L-head cylinders. Other chassis specifications include left drive and center control, open driveshafts with two universals, disk clutch, semifloating rear axle, 34 by 4 tires on all models, Gray & Davis cranking and lighting, Atwater Kent ignition, Stromberg carbureter, Stewart vacuum gasoline feed from tank at the rear of the chassis, and drive through platform rear springs.

A special point is made of the short wheelbase—113 inches for the four and 121 for the six. By saving space at points which would not affect the comfort or convenience of the passengers, this has been accomplished. Credit is due the engineers for this wheelbase shortness, when the roominess of the bodies is considered. The open bodies are interchangeable on the two chassis, and have a distance from the dash to the front edge of the rear seat of 74 inches, and from the dash to front seat of 23 1-2 inches.

Individual Front Seats

Both the bodies and the chassis are practically identical, such differences in dimensions as are to be found being incident to the longer motor of the six. A feature of the touring body is the use of individual front seats, these providing a passage way from front compartment to tonneau. The arrangement aids in the ventilation of the front compartment and makes it easy to manipulate the one-man top.

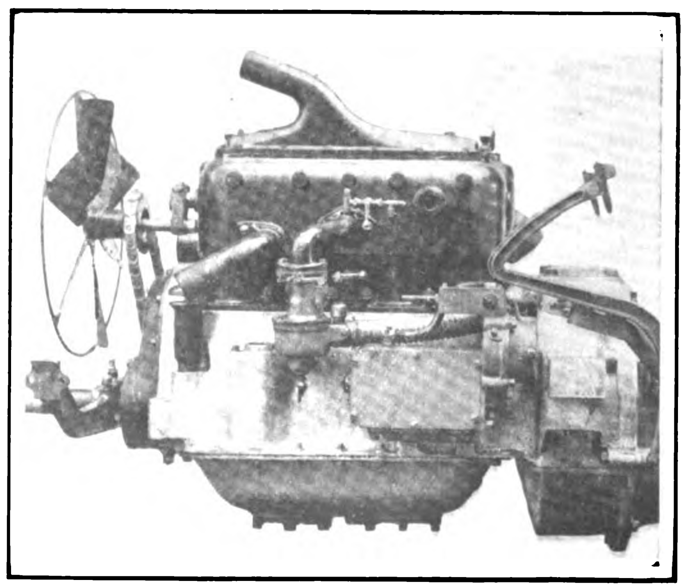
Other than the differences due to the two additional cylinders, there are only two dimensional items not alike in four and six engines. These are the bore and the valve diameter. The four is a 3 3-4 by 5 motor, and the six a 3 1-2 by 5. The former has 1 7-8 valve diameter and the latter 1 11-16. Despite the fact that the S. A. E. formula, which is based upon 1,000 feet per minute piston speed, accords the four 22.5 horsepower and the six 29.4 horsepower, the former develops 38 and the latter 50, they reaching their highest efficiency at 2,000 revolutions per minute, which is a piston speed of about 1,666 feet per minute with this stroke of 5 inches. The piston displacement of the six is 288.6 cubic inches and of the four, 220.92 cubic inches.

The general arrangement of the motors places most of the external fittings on the right side. Valves are all on this side, as well as the exhaust manifold with individual opening to each cylinder. The generator shaft is here also. It drives a centrifugal water pump on the six, the four having thermo-syphon cooling. On this shaft there is also a gear for driving the single-cylinder Kellogg tire pump.

On the left are only two parts, the Stromberg carbureter and the cranking motor which gears to the flywheel. There is no external intake manifolding, the distribution of the gases to the several intake ports being through cored passages within the cylinder casting. Only a single opening in the center of the block communicates with the carbureter through the intermediary of a short L tube. The fan has adjustable belt drive at the front end.

On these motors, crankcase and oil pan are separate; the former is an aluminum casting. The latter is made of pressed steel, thus saving several pounds in weight over cast aluminum. All bearings are carried in the crankcase and are accessible after the oil pan is removed.

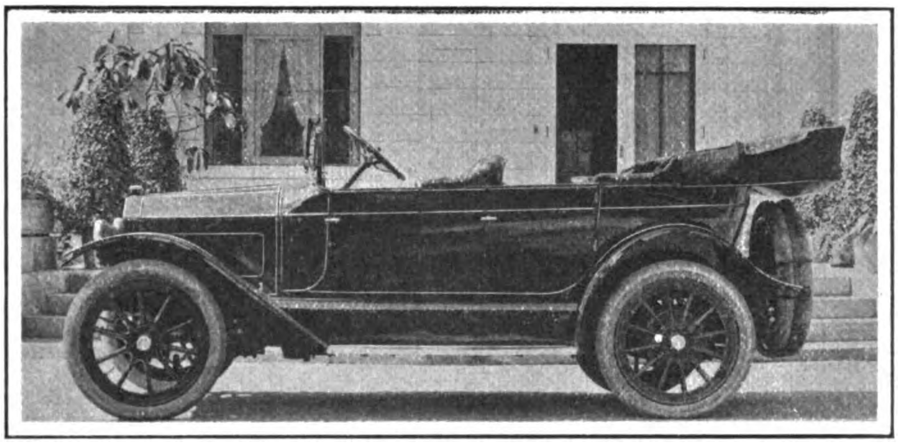
The pistons cast from the same grade of metal as used in the cylinders carry three, diagonally-split, eccentric, expansion rings which, having gone through a special machining process which relieves all strains, are ground. Oil grooves



Left side new Peerless four motor, showing mounting of carbureter are turned on the outside of the piston for distributing the oil splash over the cylinder walls, yet special provision is made to prevent excessive amount of oil reaching the combustion chamber.

The piston pin is of special steel tubing, hardened and ground to size, is held stationary in the piston bosses by a locking device and has its bearing in a large bronze bushing which is pressed into the connecting-rod. Ample lubrication is obtained through an opening in the upper end of the connecting-rod in which oil from the splash is trapped.

Connecting-rods are I-beam .35 carbon steel, drop-forged and heat-treated. The crankshafts of both motors are three-bearing types with well proportioned and liberal sized bearings. It is made of a special crankshaft steel, drop-forged and heat-treated, giving a tensile strength of 90,000 pounds per square inch. Flanges are provided on both ends of the center bearing to take any end thrust which may be imparted from the clutch or other source.



Peerless all-purpose four-cylinder touring car listed at $2,000

The camshaft is drop-forged from a single piece of low carbon steel, the cams being integral with the shaft, which runs on three large, white bronze bearings, lubricated from oil pockets cast in the crankcase for this purpose. The camshaft may be readily withdrawn after removing the gearcase cover.

The crankshaft bearings and connecting-rod bearings are made of nickel babbitt, backed with bronze and held in place by brass retaining screws. Bearing adjustment is secured by means of a number of punched sheet steel shims varying in thickness from .002 inch to 1-16 inch.

Valves Are Interchangeable

Inlet and exhaust valves are interchangeable and have nickel steel heads electrically welded to carbon steel stems. The clearance around the valve heads is so proportioned as to attain the best efficiency, and the ends of all the valve stems are hardened to insure against wear from the tappet action. The removable metal plates which cover the valves not only keep them free from dirt, but also tend to quiet the motor.

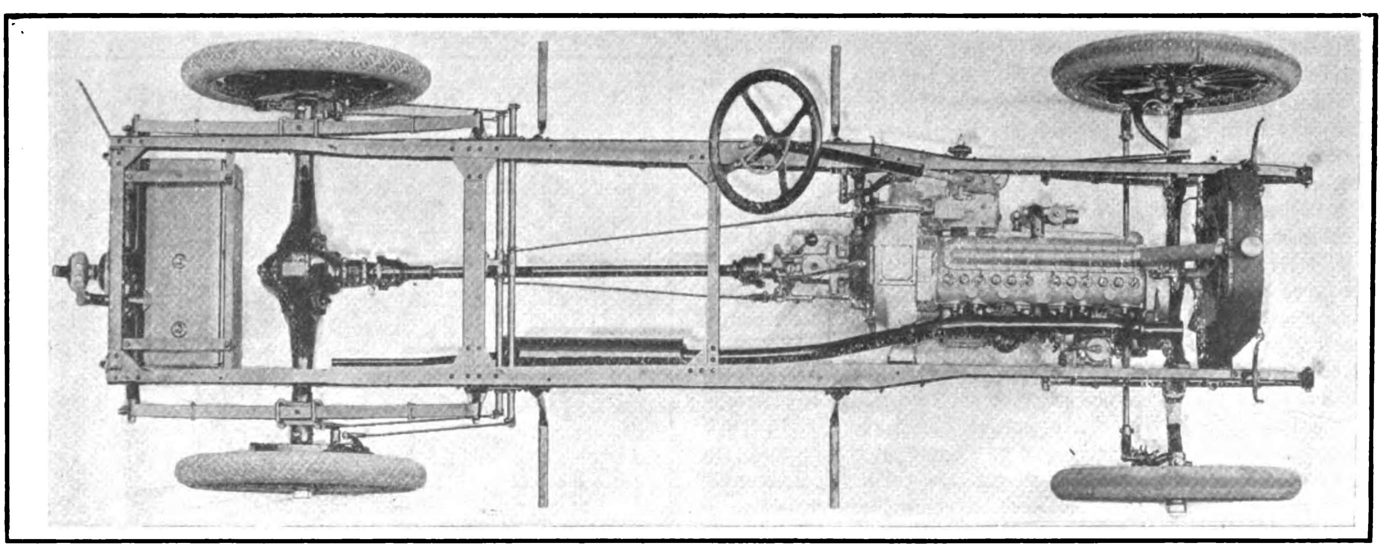
Both the four and six-cylinder motors have a combination force feed and splash system of lubrication. A horizontal plunger pump driven by an eccentric on the camshaft forces oil through copper tubes direct to the timing gears and main bearings. It then drains back into the oil troughs, thus maintaining a level for the splash lubrication of pistons, connecting-rods and other bearings. From the oil troughs it overflows into the oil pan, passes through a filter which removes any foreign particles and is again picked up by the pump.

Timing gears are helically cut and in order to secure best results, particular attention has been paid to the maintenance of accurate gear centers. Each set is housed in the usual gear case on the front of the motor.

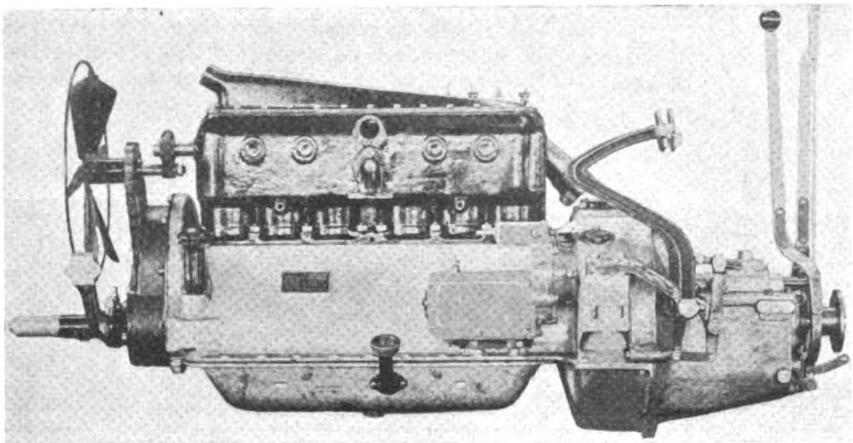
Vacuum Fuel Feed

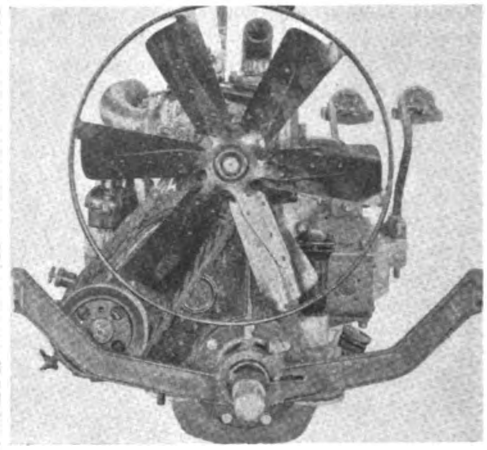
Gasoline is supplied from a 20-gallon tank at rear of car to the carbureter through Stewart vacuum feed system. The upper chamber of the gravity tank on the dash receives fuel drawn up from the main tank due to action of vacuum in the inlet manifold. When the upper chamber becomes filled, the contents are automatically discharged into the lower reservoir, whence gasoline flows by gravity directly to the carbureter. This system does away with the pumps, gauges and filters necessary on the older pressure feed systems and makes an especially neat installation on small and medium sized motors.

Ignition is provided by the Atwater Kent Unisparker which receives current at 7.5 volts from dry cells for cold weather starting, and 6 volts from storage battery for regular running. The dash switch is of unique design which automatically provides for frequent reversal in direction of primary current through the interrupter, thus lengthening the life of the contacts. Interrupter, distributer and governor providing automatic advance, are combined in a com-



Peerless six chassis, showing block motor, left drive, center control, main fuel tank at rear and platform spring





Left—Intake side of new six-cylinder Peerless power plant. Right—Front view of motor, showing pivot support for front end

pact unit positively driven from the shaft of the lighting generator. Open wiring is employed, the high tension leads to spark plugs being carried on fiber block insulators to insure protection against leakage or grounds.

Single Wire Lighting

The lighting system is a single wire type using Gray & Davis 6-volt generator. The generator is mounted on a bracket at the right side of the motor and is driven through a leather disk coupling on the gear-driven shaft. The generator also is arranged to carry and drive the igniter unit.

The generator is a variable-speed, shunt-wound type T machine with cut-out coil and two-point voltage regulator mounted thereon. The shunt winding of the coil causes the generator to cut into the lamp and battery circuit at 600 revolutions per minute. Voltage is then regulated against effects of fluctuations in engine speed by means of the two-point regulator which automatically inserts or cuts out resistance from the two generator shunt field windings. A main cut-out acts also as protection for the generator against possible reverse currents from the storage battery.

No Side Lamps Needed

Head and service lamps are combined and provided with two bulbs, one of 15 candlepower for country driving and the other of 4 candlepower, and out of focus, for city driving. The storage battery is a 6-volt 80-ampere-hour Willard, common to both lighting and starting systems and interchangeable on models 54 and 55. Dry cells are provided for emergency ignition.

The cranking unit is a Gray & Davis type Y, series wound, motor, mounted on a bracket at the left side of the engine and driven through a self-contained countershaft and pinion, meshing with a ring gear on the flywheel only when starting. The operation of starting consists in pulling a knob on the instrument board which transmits force through leverage and a helical spring to the sliding pinion on the countershaft. The helical spring causes meshing the instant the pinion begins to turn over.

The electric motor gives a breakway torque at the crankshaft of approximately 285 foot pounds. It will spin the engine at 125 revolutions per minute with a current consumption of 70 amperes, which speed is so high as to insure easy starting of the engine in all weather, it is said.

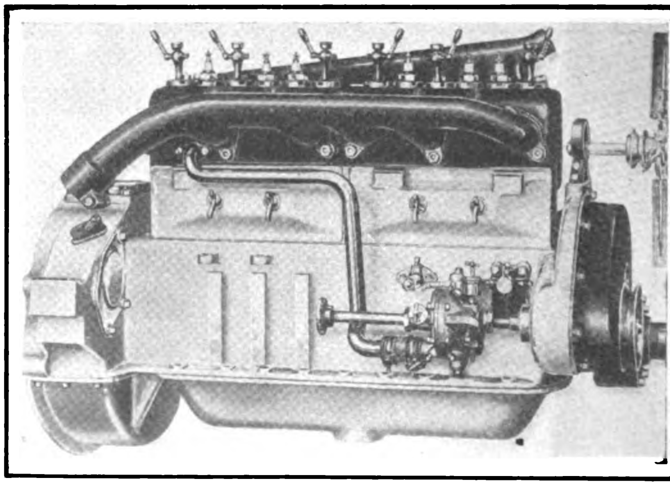
Clutch and change-speed gearset are assembled in a single transmission unit with case bolted directly to motor bell housing. All moving parts are protected by the aluminum case and are accessible for inspection through removable plate and cover. The units are interchangeable on models 54 and 55.

The clutch is of the multiple-disk type and controlled by pedal through ball bearing thrust, a special lever design providing easy clutch action and pedal adjustment. Inside clutch plates are 3-32-inch stock hardened and ground. Outside plates are cold rolled steel covered with asbestos friction surface and driven by twelve case-hardened keys, riveted to the pressed-steel clutch driving-drum.

The gearset is a sliding, selective, with three speeds forward and one reverse. Gears are 6—8 pitch with wide face, and are of 3 1-2 per cent. nickel .20 carbon steel, heat-treated and carbonized. Other features are a square driveshaft of .80 carbon, crucible tool-steel, tempered; Timken roller bearings on mainshaft; S. R. B. ball bearings on countershaft; die-cast, babbitt pilot bearing and special ball thrust bearing between front and rear members of the mainshaft.

Universal joints are provided at both ends of the open propeller shaft. These joints are packed in grease and oil, and are protected from leakage and dust by sheet metal boots. The propeller shaft is integral with the universal joint member at the rear axle end, while at the gearcase end it has a fluted sliding joint, thus providing for movement of the rear axle on rough roads. The propeller shaft center is of steel tubing.

The rear axle is semi-floating, with the main housing of reinforced pressed steel with pressed steel rear cover. The differential and pinion shaft form a unit with the front cover, thus insuring alignment, yet giving commendable accessibility. The pinion shaft and differential are each carried on two taper roller bearings which care for both the radial and thrust loads. The pinion is of 3 1-2 per cent. nickel steel and the gear is of nickel-chrome steel. They are of the helical bevel type which insures quiet running. Live axles are of



Exhaust side of six, showing cover plates inclosing valves, etc.

1 1-2-inch nickel-chrome steel provided with single taper roller bearings near the outer ends to take the wheel load.

Easy Brake Adjustment

There are the usual two sets of hub brakes. The foot or service brakes are of the contracting-band type while hand brakes are of the expanding-shoe type. Both are provided with asbestos friction lining. Adjustment of service brakes is made simple through the use of wing nuts.

The new cars have a pressed steel frame of 4-inch channel section, dropped at the rear and inswept at the front. Frames of both models are of the same general design, but the dimension from dash to front end is 8 inches longer on Model 55. The frame is trussed to give maximum stiffness with minimum weight.

Platform type of rear spring suspension, which has been featured on former Peerless cars, is continued on Models 54 and 55. Lightness and simplicity of chassis are furthered in these smaller models by eliminating radius rods and using the rear side springs to take the drive from rear axle to frame. They also take the torque reaction, thus permitting the omission of a separate torque member.

Data on New Peerless Motors

	FOUR	SIX
Firing order	1-3-4-2	1-5-3-6-2-4
Valve diameter (inlet and exhaust)	1 7-8 inches	1 11-16 inches

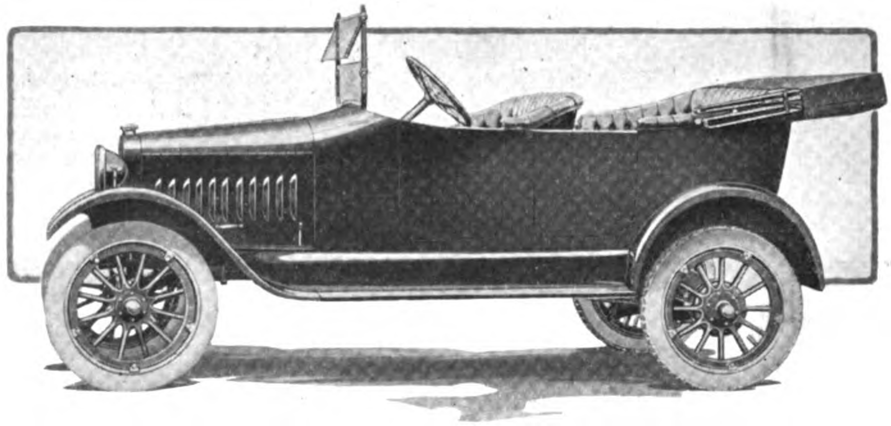
Connecting-rod length	10 1-4	10 1-4

Saxon Six To Sell for $785

FOLLOWING up its success in the field of low-priced fours the Saxon Motor Co., Detroit, Mich., has joined the move for really low-priced sixes. Bringing out a car with a power plant of this type for $785 is the newest development offered by this Detroit concern.



Five-passenger, six-cylinder Saxon touring car, which sells for $785, completely equipped

To take care of the added production facilities necessary in marketing the low-priced four and six-cylinder cars, as reported elsewhere in this issue, the company will take over the building formerly occupied by the Abbott Motor Car Co., in Detroit. The output of the four will be increased and the Saxon company states that the price of the six is based upon an output of 25,000 cars.

The new model is fully equipped and mounted on a 112-inch wheelbase and uses 32 by 3 1-2 tires. It has a five-passenger capacity. The tread is standard 56 or optional 60-inch width. The motor has its six L-head 2 7-8 by 4 1-2-inch cylinders cast in a block. The valve action is inclosed by cover plates and the valves are of nickel steel with carbon-steel stems.

A drop-forged steel crankshaft of 1.875 inches in diameter carried on three main bearings is used. The camshaft is also a drop forging of 1-inch diameter and is carried on four bearings. The cams are integral with the shaft which is driven by helical gears.

Thermo-Syphon Cooling

Oiling is by splash to the cylinders but by pressure to the main bearings, the circulating pump taking the oil from the crankcase to these bearings and from this point a gravity flow carries the oil into the splash trough. The oil is carried through a strainer before again reaching the pump to be re-circulated. Cooling is by thermo-syphon with a cellular radiator and fan.

Ignition is by the Atwater Kent system which provides either automatic or hand control. Gasoline is fed by gravity from the 10-gallon tank located in the cowl.

Power is taken from the motor by a multiple disk dry-plate clutch with steel against Raybestos bearing surfaces. The gearset provides three speeds forward and is mounted on the rear axle being carried on Hyatt roller bearings with ball thrust. The driven pinion gear is adjustable and the shafts are all of nickel-steel. The shaft connecting the clutch and gearbox is of solid alloy steel 1-inch in diameter with two universal joints and with a concentric torque tube.

Two sets of brakes are used on the car, both of which are on the rear wheels. The service brake is external contracting, 10 inches in diameter with a 2-inch space. The emergency is internal expanding having a diameter of 9.75 inches and a face width of 2 inches. Both these brakes are lined with Thermoid. The steering gear is a worm and full gear with a 17-inch wheel. The steering connections throughout are all drop-forged and heat treated.

The front axle is a single-piece I-beam drop forging, heat treated, with ball bearing in the hub. The rear axle is three-quarter floating and is contained in a pressed steel housing. The main driveshafts are alloy steel 1 1-16 inches in diameter. The differential is a two-pinion design carried on Hyatt rollers. The frame is a channel section of .25 carbon steel.

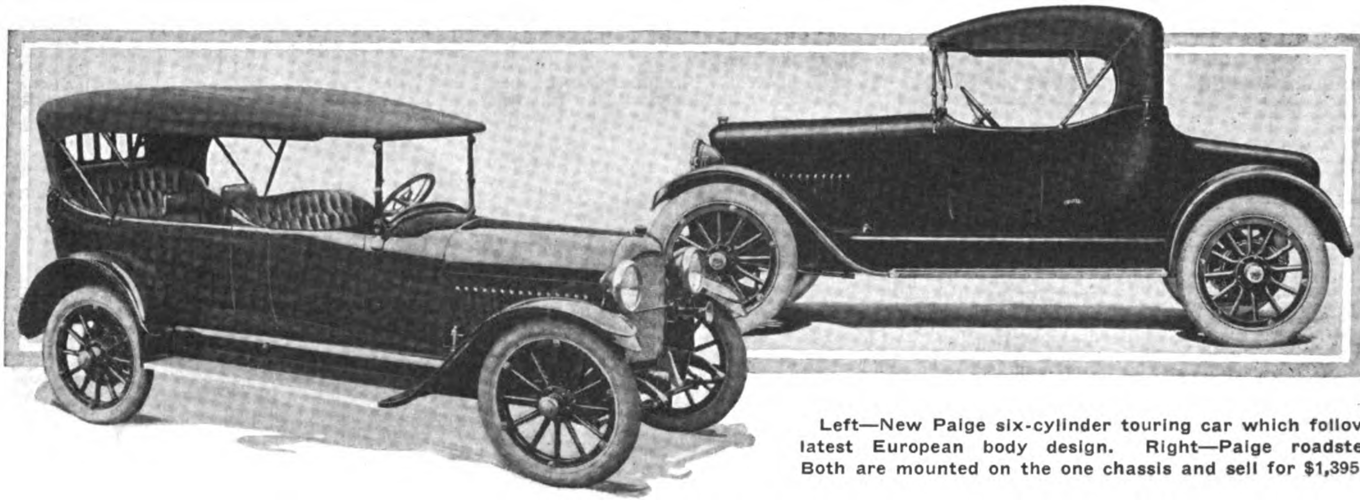
Cantilever Springs Used

The springs are cantilevers, 30 inches long and 2 inches wide. They are of vanadium steel. The bodies are designed to have the maximum room. The streamline touring design seats five passengers. The distance from the heel board to the dash is 28 inches. The front seat inside the upholstery is 41 inches wide and 16 inches deep. The rear seat inside the upholstery is 47 inches wide and 18 inches deep. The front cushions are 7 inches in depth and the rear cushions 8 inches. The doors are 19 inches wide for the front and 21 inches for the rear. All doors have concealed hinges. The standard color is Richelieu blue with black running gear.

The equipment includes electric starting and lighting without side lamps, but with dimming bulbs in the headlights. Top, windshield, speedometer, extra rims, etc., are also included in the equipment.

Paige Has New Block Six at $1,395

Made in Both Touring and Roadster Form—Streamline Bodies and Crowned Fenders



Left—New Paige six-cylinder touring car which follows latest European body design. Right—Paige roadster. Both are mounted on the one chassis and sell for $1,395

THE Paige-Detroit Motor Car Co., Detroit, Mich., is bringing out a new six under the model number of 6-46. Mounted on a 124-inch wheelbase, either a touring car or roadster may be had at $1,395, with streamline body and full equipment.

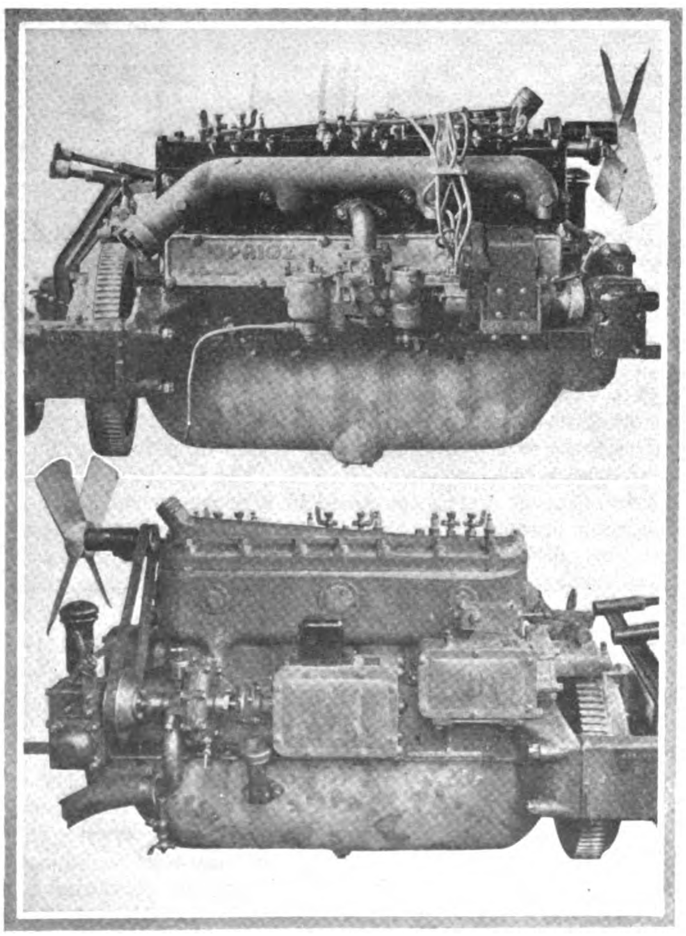
The power plant used in connection with this new car is a Continental product having its six L-head 3 1-2 by 5 1-4-inch cylinders cast in a single block. The material used in the cylinders is reverberatory air-furnace iron. The cylinders and the upper half of the crankcase are cast together, a feature which is claimed to add both accessibility and strength. The cylinders are bored and ground to a finish fit. A three-speed gearbox is provided.

Detachable Heads

The waterjacket heads are cast separately and are fastened to the cylinders by twenty-two bolts. Water leakage is prevented at the point of connection by a copper asbestos gasket. When these heads are removed the interiors of the cylinders are accessible for inspecting the valves, pistons and cylinders. The oil pan is of stamped sheet steel and the false bottom containing the oil troughs is separate, being riveted to the pan.

Valves on the Right

The valves are all on the right side and are completely housed with aluminum plates giving an oiltight chamber in which the valve action operates. The valves are all driven from a single camshaft. The camshaft taking its drive from a cross shaft at the front of the motor. The latter shaft also serves for the magneto, generator, water pump and the fan pulley. A bronze spiral gear on the end of the crankshaft drives a cross shaft which in turn drives all the auxiliary parts to steel spiral gears which operate in oil. This form of drive is claimed to be as quiet as it is possible to secure and at the same time to be accurate in keeping the timing of the valves correct under all conditions. Because the parts having frictional contact run in oil, the wear is reduced to a minimum.



Upper—Right side of motor showing piping and mounting of carbureter and magneto

Lower—Left side of motor showing water pump, oil gauge and starting and lighting units

The electrical equipment is provided by Gray & Davis for lighting and starting and by Bosch for ignition. This is a two-unit installation, 1 unit, the Gray & Davis motor generator takes care of lighting and starting and the Bosch magneto takes care of ignition. The mounting of the starting motor and generator is such as to provide accessibility with an aim of maintaining freedom from dirt, grease and oil.

Two arms extending from the back of the motor form a housing to which is fastened the gearset housing providing a unit transmission. The clutch is in the flywheel and is a multiple disk with cork inserts. The continuous housing is oil-proof, allowing the clutch to operate continuously in a bath of lubricant. The drive is transmitted through a three-speed gearbox to a driveshaft having two universal joints. The rear axle is a three-quarter floating design with a housing of malleable iron. A .625-inch crossbar takes the strain of the road shocks from the axle housing.

Cantilever Spring Suspension

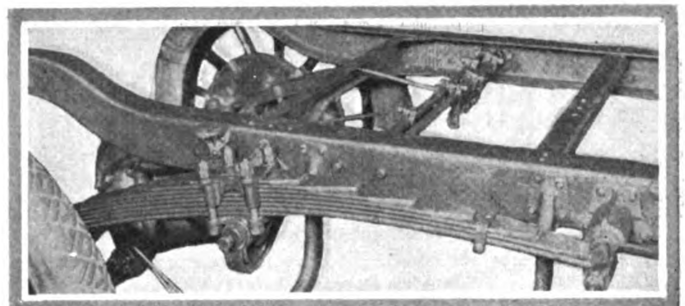
The brakeshafts are mounted on stiff brackets. There are two sets of brakes on the rear wheels. The drums are 14 inches in diameter and the face width is 2 inches. Cantilever spring suspension has been adopted. The length of the springs is 48 inches and the width 2.5 inches. The drive is taken through the cantilever springs and through the torque arm. The front axle is an I-beam section drop forging. Spring pads are forged integrally with the axle and have a curved shape so as to conform with the spring seat. The spring leaves are made of high carbon steel, heat-treated, for resiliency and strength. The spring eyes are provided with means of lubrication.

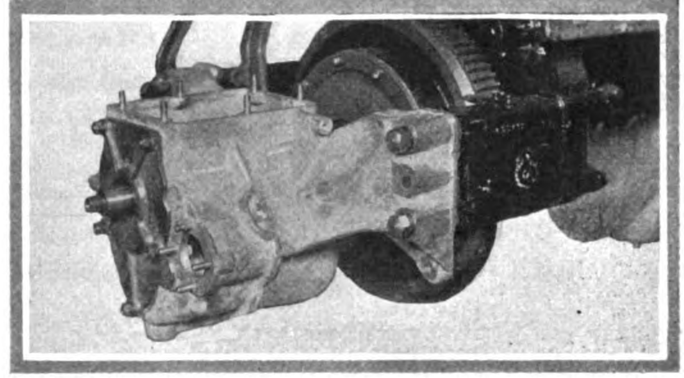
Easy Steering Control

Irreversible steering is used. The trunnion arm is in a straight line so that the road shocks transmitted to the wheel do not give a turning moment on the steering wheel thus removing the strain from the driver's hands. This gear is a nut-and-sleeve type made by the Jacox company.

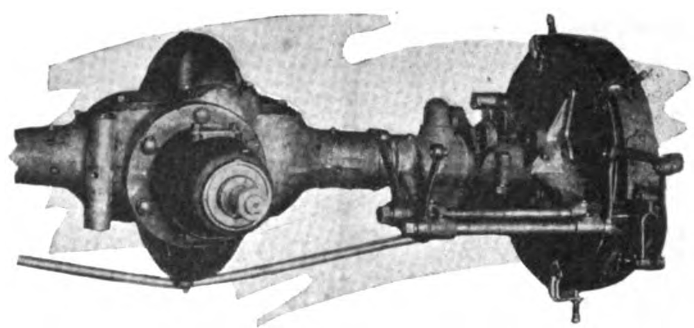
Streamline Body and Crowned Fenders

The body is a streamline design capable of carrying seven passengers. The doors are U-shaped with flush tops. The upholstery is of leather and the tonneau is supplied with a foot and robe rail. Two auxiliary disappearing seats fold against the back of the front seats. The fenders are of the latest design, being crowned. Running boards are steel stampings covered with linoleum. Equipment is complete.

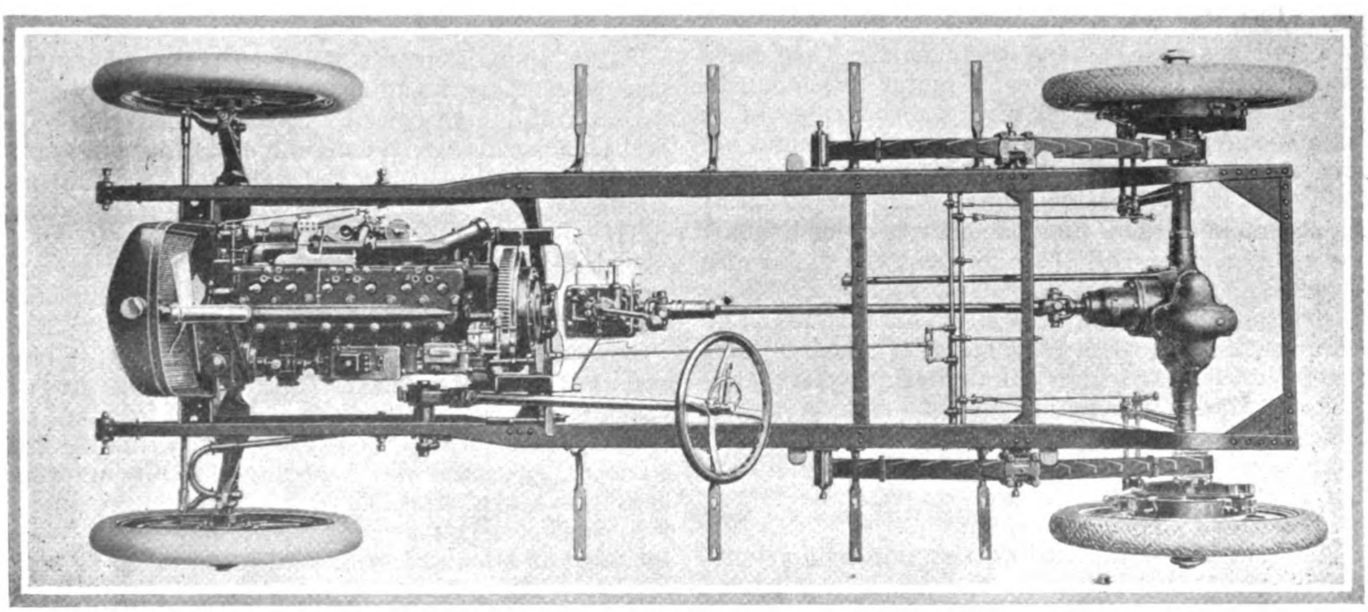




Upper—Paige cantilever spring construction. The drive is taken through the springs but the torque reaction is taken care of by a torque arm. Lower—Gearset showing attachment to crankcase. Note teeth on flywheel for starting the motor by Gray & Davis system



Rear axle illustrating details of differential housing and brake members. A cover plate makes the differential easily accessible and the driving pinion may also be removed without much difficulty



Plan of Paige chassis showing block motor in unit with gearset, contilever rear springs and three-quarter floating axle. The frame is strongly braced

Speedway Opportunities

WITH practically double the number of automobile speedways for next year, it is anticipated that the use of these special speed creations will be broadened and that something more than speed and endurance will result. Races have done much for the advancement of the motor science and are still playing their part. They have been pioneers in many lines of motor development.

But a greater variety of tests can be conducted on these speedways, tests which, while they cannot vie with the speed spectacle in public approval, nevertheless do much to solve many of the problems of the automobile. The fuel efficiency tests of the last few months have had their lessons; the endurance tests have brought out not a few factors in motor lubrication and cooling, as well as carburetion; and there yet remains room for a series of research tests that would be particularly illuminating. The question of wind-resistance at various speeds is not appreciated as it should be and some research tests along this line would be very valuable to manufacturers and interesting as well as valuable to car owners.

The question of lubricating the motor of a touring car when traveling with its load and equipment at maximum speeds is a problem yet far from being settled with all makers. True this condition is not frequently met with in regular use, but it is for the extreme cases that the factor of safety must be provided. Oil temperatures at different sustained speeds could be measured; tire temperatures and pressures might be noted; the question of wheel slip at different speeds is a vital factor in tire wear and could be looked into to advantage; in fact, there are several forms of research tests that could be carried out, tests equally essential to the maker, the dealer and the user.

Body Comforts

IT is rarely that any one season witnesses so many refinements in body construction and finish as are found in many of the 1915 cars. Frequently more than a dozen alterations of one nature or another exist, all carried out with the one thought of giving greater comfort to the passengers. That this is essential is well borne out by the comment of a pioneer automobilist, who has been driving cars since the days of the early steam types, to the effect that comfort in riding is today one of the major considerations in an automobile, if not the great one!

Comfort has been increased for next season by a general improvement in seat design, the cushions in many cars being properly tilted to meet the needs of the passenger, as well as the upholstery being heavier in most low and medium-priced machines.

The low body is always desirable, and many of the new models are well featured in this respect. The underslung spring has played its part in this movement, so has the dropped frame, and so has the dropped front axle.

Four-passenger bodies give evidence of being slightly more popular than the present year, this tendency being in line with European trends previous to the war. The four-passenger body gives a much better design, getting away from the width at the back seat and making it possible to have the maximum body width between the front and rear seats, if so desired. This design adds to the streamline effect.

Early announcements point to more colors than this year, there being many more color options in medium and high-priced cars than formerly. The staid black will not be so dominating, notwithstanding the natural tendency the war would have toward somber colors. While black is the great predominating tone and greens, blues and grays in many varieties have large followings, there are many concerns that are giving other semi-gaudy color combinations that should suit the most fastidious.

Production and manufacturing requirements have produced a few tendencies for next season. In general there are fewer body models with many of the lower-priced cars, the one-body policy taking hold in not a few cases. With medium and higher-priced cars there are often more models than formerly, the cabriolet, coupelet or other new ideas being included as standard types and often listed as stock models. The number of limousines has not materially increased, but coupés and sedans are more in evidence.

Washington Road Men Want H.P. Tax

225 Delegates at State Good Roads Assn. Meeting Adopt Resolutions for Increasing Highway Funds

SEATTLE, WASH., Nov. 26—Closing the most interesting, educational and successful session in the 15 years of its existence, the annual convention of the Washington State Good Roads Assn. adjourned at Spokane last week to meet in November, 1915, at Ellensburg, Wash. Two hundred and twenty-five delegates representing twenty-two counties and representatives from Oregon, Idaho and Montana, were in attendance at all four sessions held during the 2 days' convention.

Serious consideration was given the subject of road maintenance, and the convention adopted resolutions urging the Washington legislature which meets in January to increase the present maintenance fund of 5 per cent. The resolutions also declared in favor of completing the comprehensive construction program begun in 1913 before additional appropriations are made for extensions and laterals; that the present levy of a mill for state roads and a mill and a half for permanent highways, which annually produce approximately $3,500,000, be continued; that automobiles be taxed in proportion to their horsepower, the receipts therefrom to go into a maintenance fund and returned to the counties from which the money comes; that a new and more modern automobile code be adopted; that a compulsory road dragging law be enacted; that danger signs and signals on all roads be standardized; and the continued use of convicts on roads under the present honor system was favored.

Never before in the history of the Pacific Northwest was so much genuine interest displayed in a good roads convention. Speeches, papers and stereopticon illustrated lectures were given by men of national prominence. The office of Public Roads, United States Dept. of Agriculture, was represented by E. W. James, who delivered an address on highway maintenance, which subject was the keynote of the convention. Others who spoke were Governor Ernest Lister, of Washington; Lieut. Governor Louis H. Hart; former Governor M. E. Hay; Governor-elect Alexander, of Idaho; Samuel Hill, president of the American Roads Builders' Assn.; and H. S. Earle, of Detroit.

Lincoln Highway Is Now Complete

DETROIT, MICH., Nov. 28—Every mile of the 3,389-mile Lincoln Highway is now in condition. A demonstration such as was never before made in connection with any good roads movement was made yesterday by all the consuls of the Lincoln Highway Association. Along the entire route, from coast to coast, each consul or some one representing him, drove over that section or part of the route over which he has jurisdiction, for the purpose of demonstrating that the road is fit for travel. Thus about 200 Lincoln Highway workers took part in the run, which was started as near as possible everywhere about 6 a. m. and completed as near as possible by 6 p. m., to make it a 12-hour run.

The runs ranged as to distance from 8 and 10 miles to over 300 miles, although this was quite exceptional. In addition to inspecting their territory the consuls and observers will later make detailed reports as to what is still to be done in their respective section. The principal object of the demonstration has however been to show that it does not require any longer that a tourist take side roads or other roads than the official Lincoln Highway route.

Wants Better Roads in Mt. Rainier Park

WASHINGTON, D. C., Nov. 30—Motor cars and motorcycles contribute so large a share of the revenues of the Mount Rainier national park in the state of Washington that Ethan Allen, superintendent of the park, in a report made today to the Secretary of the Interior, predicts that as soon as the roads are improved so that these vehicles can move with safety over all of them the revenues will be sufficient to meet the expenses of an economical administration of the park affairs.

Desirous of getting this revenue just as quickly as possible, Superintendent Allen recommends expenditure of funds for road improving, and suggests that an "engineer corps" be attached to the park service to prepare improvement and maintenance details.

The report shows that during the year ended September 30, 1914, 1,594 permits were issued to owners of private motor cars to use the roads of the park for travel. These permits are good for repeated entrances until December 31 of the year of issue. For each of these permits a fee of $5 was exacted, making the revenue collections from this source $7,970, while public motor cars paid $650. "It is confidently predicted," says Superintendent Allen, "that park revenues will be sufficient to meet the expenses of an economical administration of park affairs as soon as the present road is permanently improved and safety and comfort assured to motor car users."

59,507 Fords Sold in 3 Months

DETROIT, MICH., Nov. 30—During the first 3 months of the buyers' profit-sharing plan of the Ford Motor Co., which started August 1, 1914, a total of 59,507 Ford cars were sold, or an average of 19,835 cars per month.

The buyers' profit-sharing plant calling for a return or refund of $40 or $60, according to the car bought, provided that between August 1, 1914, and August 1, 1915, a total of 300,000 cars are sold and delivered, the 59,507 cars sold to October 31 represent a refund of at least $2,380,280 on the basis of a rebate of only $40 per car. By taking the average of $50 as the return to each buyer, the amount to be returned by the Ford company would be $2,975,350 for the first 3 months' business on the new plan. If the 300,000 cars are sold and delivered then the return to buyers will amount to between $12,000,000 and $15,000,000.

Argo Production 750 Per Month by March

JACKSON, MICH., Dec. 1—W. R. De Voe, of the Argo Motor Co., states that the first run of the company of 200 cars is in full swing and will be completed about the time material for the second lot, 500, reaches it around December 5. These are to be followed by 500 cars in January, and it is anticipated a production of 750 per month will be reached by March 1.

Canada's Imports 1,406 Cars Under 1913

OTTAWA, CAN., Nov. 30—Canada's imports of automobiles even in war times continue to increase. During September, the second month of the war, Canada imported from the United States 260 automobiles, as compared with 253 in September, 1913. Total imports for the 9 months of 1914, however, show a contraction of 1,406, this year's imports being 3,854, against 5,260 in 1913.

Canada Forbids Rubber and Graphite Exports

OTTAWA, ONT., Nov. 30—An order-in-council has been passed forbidding export from Canada to any country other than part of the British Empire of rubber and graphite. This action has been taken to prevent supplies of the commodities reaching Germany. Canada imports $4,000,000 worth of crude rubber each year and exports about $500,000. About $120,000 worth of graphite is exported, principally to the United States, and the production in Canada amounts to about $100,000 worth per year. It is produced at Buckingham, Que.; Calabogie and Port Emsley, Ont.

DETROIT, MICH., Nov. 30—Walter B. Brady, for the past 6 years special representative with the Studebaker sales department, has resigned to join the Maxwell forces in the same capacity beginning December 1. Mr. Brady was the oldest of the present Studebaker organization in point of years of service. He will travel the entire United States in the Maxwell interests.

Saxon Leases Abbott Factory

Adds 120,000 Square Feet—To Increase Production of Fours and New Six-Cylinder Car

DETROIT, MICH., Nov. 30—The Saxon Motor Co. has taken a 5-year lease of the plant of the Abbott Motor Co., and will occupy the premises January 1, 1915. This will give the Saxon company a total floorspace of 180,000 square feet, of which 60,000 are in the present plant of the Saxon company on Bellevue avenue.

For some time the manufacturers of the Saxon cars, whose business has increased very rapidly, have contemplated either locating in another city offering suitable inducements for a new plant, or building a new plant in Detroit. When it became known that the Abbott company contemplated locating in another plant negotiations were started with that company. Recently the Abbott plant at Beaufait avenue and Waterloo street was purchased by Wallace Bros., from the purchasers of the Abbott assets, but this deal also involved the transfer of subdivision real estate valued at $40,000 and the final transaction was only concluded last week.

It is rumored that the Saxon company will some time next year have a new modern plant erected on Bellevue avenue. At the present time this cannot be undertaken without interfering greatly with the general workings of the company.

The Saxon Motor Co. was organized the latter part of 1913 and has a capital stock of $350,000. The leasing of the Abbott plant involves, all told, about $140,000.

The Saxon company will for the time being continue to occupy its present plant at Bellevue avenue, but as soon as it will be possible the whole works will be located in the Abbott plant, which will be altered or such changes effected to suit the Saxon requirements.

Automobile Securities Quotations

NEW YORK CITY, Dec. 1—Automobile stocks in general experienced a slight increase in the trading on the curb and in private deals this week and tire securities made an even better showing. The following bid and asked quotations are those which a prominent brokerage house finds to obtain in private sales and are to be taken only as a guide until the re-opening of the Stock Exchange.

The par value of these stocks is $10.00, all **others** $100.00.

Buick Ships 125 Cars a Day

FLINT, MICH., Nov. 28—Although the working force of the Buick Motor Co., was reduced somewhat November 1, an average of 125 cars were made and shipped daily this month, with several higher marks of 150 to 175 and with a low mark of eighty. This was due to the shortage on freight cars as whenever a sufficient number of railroad cars were available they were generally all filled.

Up to the middle of this month the company was fully 10,000 cars ahead in production and sales over the number at that time of the year in 1913. The following figures show the actual number of the year's new models made during July, August, September and October, 1913 and 1914, and represent at the same time the number of cars delivered.

1913		1914
12	July	1,849
859	August	4,671
2,116	September	5,630
3,450	October	5,219
6,437		17,369

Thus in those 4 months of 1914 the company made 10,932 more cars than during the corresponding period in 1913.

Rubber Imports 5,476,049 Lbs. in 3 Weeks

NEW YORK CITY, Nov. 30—The imports of Para rubber at this port from October 29 to November 19 amounted to 5,476,049 pounds. The largest shipment was on October 29, when 1,379,626 pounds were brought in on the steamer Denis from Para and Manaos. The November 19 shipment amounted to 539,147 pounds by the steamer Sao Paulo from Para. The receipts of rubber from Para during the month of November amounted to 1,200 tons, with 400 tons more now afloat for December arrival. The receipts of plantation rubber amounted to 2,583 tons. It is estimated that there is now afloat from Ceylon to London about 700 tons of plantation, in three boats, namely, the St. Egbert, City Delhi and Kabinga, but under the present embargo, of course, none of this will reach the New York market. Advices from Germany are to the effect that all the crude rubber in that country is now being used for tires and other military equipment.

U. S. Rubber Export Co., Ltd., Incorporated

NEW YORK CITY, Nov. 30—The United States Rubber Export Co., Ltd., which has been incorporated under the laws of Delaware with an authorized capital of $100,000, will be a subsidiary of the United States Rubber Co. to handle the export business of the parent company and of its various subsidiary manufacturing companies.

The incorporators are: J. D. Carberry, assistant secretary of the United States Rubber Co.; Samuel Norris, secretary of that company, and F. V. Glynn, who is attached to the secretary's office. Next week the organization of the company will be completed by the election of directors and officers.

Lower Prices on Federal Casings

NEW YORK CITY, Nov. 30—The Federal Rubber Mfg. Co., Milwaukee, Wis., has announced a reduction in prices on its rugged tread casings. The new prices, effective December 1, 1914, are as follows:

SIZE	FORMER PRICE	PRESENT PRICE
30 x 3	$18.20	$13.80
30 x 3½	24.30	18.50
31 x 4	31.55	25.70
33 x 4	33.70	27.55
34 x 4	34.80	28.50
36 x 4½	45.65	40.95
36 x 5	55.60	47.65

Finds Western Conditions Greatly Improved

CLEVELAND, O., Nov. 25—C. A. Emise, sales manager of the Chandler Motor Car Co., has returned from a trip through the South and Pacific coast, during which he visited sixteen states. Everywhere conditions were found greatly improved, in fact they are quite normal, according to Mr. Emise. In the territory west of the Mississippi river the dealers declared themselves very optimistic over the business outlook for 1915. "The great irrigation projects in Arizona, New Mexico and Western Texas are inaugurating a wonderful era in agricultural prosperity, which is bound to have its effects on the sale of automobiles," said Mr. Emise. "In Texas and the other southwestern states the recent improvement in the cotton situation has started a renewal of business acivities all along the line. Cotton planters and brokers are confident that within a very short time the South will forget the temporary embarrassment which followed the fall in the cotton market."

—

DETROIT, MICH., Nov. 30—The regular quarterly dividend of 1 3-4 per cent. upon preferred stock of the Packard Motor Car Co. will be paid December 15 to stockholders of record at the close of business on November 30.

—

N. A. C. C. Co-operates with Congress

NEW YORK CITY, Dec. 2—At a meeting of the directors of the National Automobile Assn. of Commerce, Inc., held today all members were present excepting L. H. Kittredge, of the Peerless company. The question of what action the chamber shall take in fighting the present Kardo patent litigation was gone over thoroughly and definite action will be taken at the meeting of members tomorrow.

Today a trade committee was appointed, whose duties will be to co-operate with the federal authorities at Washington by furnishing them with any and all information they may be in need of with regard to the automobile industry. The feeling among the automobile makers is that there is no disposition on the part of Congress to inflict any hardships on the industry and the industry in turn is making every advancement to co-operate for the general benefit of trade.

—

PIERRE, S. D., Nov. 28—As reflecting the conditions of prosperity in South Dakota the record of ownership of automobiles is significant. From Pierre comes the word that the total number of licenses taken out this year is 20,600 and that before the year is gone the number will undoubtedly pass 21,000.

—

Gilbert Answers Allen in Patent Suit

NEW YORK CITY, Nov. 30—E. G. Baker, New York representative of the Gilbert Mfg. Co., New Haven, Conn., has filed an answer in the suit brought bv the Allen Auto Specialty Co. in the United States District Court in New York. He denies that the Gilbert tire cover infringes the Nathan tire cover patent No. 799,662, and declares the patent invalid. Aside from the usual denials in infringement actions Baker alleges that the claims of the Nathan patent, if properly restricted, do not cover the Gilbert device.

—

Lozier Hearing Postponed Until Dec. 8

DETROIT, MICH., Nov. 27—Judge Tuttle, of the United States District Court, has postponed the hearing of the Lozier Motor Co. until December 8, or the day after the meeting of the stockholders of the company, who are to decide upon the reorganization plans at a meeting specially called for that purpose for December 7.

—

Scarborough Co. Files Bankruptcy Petition

INDIANAPOLIS, IND., Nov. 18—The Scarborough Co., of this city, engaged in the business of manufacturing guide maps for use by automobile tourists, has filed an involuntary petition in bankruptcy and James W. Taylor has been appointed receiver for the concern.

—

To Sell Benham Plant Dec. 8

DETROIT, MICH., Nov. 28—The plant of the bankrupt Benham Mfg. Co., at 1882 Mt. Elliott avenue, will be sold at public auction December 8 by the Union Trust Co., trustee. The sale will be subject to confirmation by the district court. The plant consists of a two-story brick and reinforced concrete building 90 by 170, a two-story frame building 53 bv 116, another frame building 40 by 93 and a heating plant. The main building is equipped with machinery and other equipment for automobile manufacturing, while the smaller of the two frame buildings contains machinery and equipment for a wood working plant. The total value of the plant is estimated to be $50,000.

Makers of New Fuel Incorporate

—

Zoline Co., a $100,000 Corporation, to Proceed with Manufacture—Car Builders Interested

INDIANAPOLIS, IND., Nov. 30—The Zoline Co. has been incorporated with an authorized capitalization of one hundred thousand dollars. The company is to manufacture Zoline, a substitute fuel for gasoline, invented by John Andrus of McKeesport, Pa., which has been tested at the Indianapolis speedway as reported in THE AUTOMOBILE for November 26. The fuel was tried out in a 1,000-mile run by a Marmon six. The car made 7.42 miles per gallon.

All of the capital stock, except ten shares, will be issued to Mr. Andrus, Carl G. Fisher and Dr. W. H. Chambers of McKeesport, Pa., in consideration of an assignment by them to the corporation of all respective rights under a contract entered into by and between Mr. Andrus and Mr. Fisher on October 10, 1914.

Others interested in the company are James A. Allison, Ernest W. Bradford and Howard C. Marmon, Indianapolis, and Henry B. Joy, Detroit, Mich.

—

Willems Is Dodge Foreign Representative

DETROIT, MICH., Dec. 2—*Special Telegram*—G. E. Willems has been appointed as foreign district representative for Dodge Bros., assigned to territory in the Far East. Mr. Willems' appointment is understood to be the first of similar steps to be taken by this company in the near future, looking toward the building up of a stable foreign export business. For several years he represented a large French company in Egypt. Later he left for India where he took up the importation and sale of motor cars.

Market Reports for the Week

Most of the changes in the market reports this week were of the usual order. A number, however, which have been quite steady of late, made changes. These were lead, cyanide potash and rubber. Lead went down $0.10 per 100 pounds, closing at $3.80; cyanide potash dropped from $0.25 to $0.23 and rubber closed at $0.71 a gain of $0.04. Both coppers went up $0.00 1-4 per pound. There was some buying for export to France and more sales to domestic consumers for December, January and February delivery. Tin dropped $0.85 per 100 pounds, closing at $33.15. The local market was quiet. The London market was, however, strong and higher. Since the first of January the imports of tin at New York City and outports have been 39,627 tons. The oils and lubricants markets remained unchanged. The petroleum markets continue steady. Cottonseed oil rose $0.21 a barrel, closing at $5.75.

Peerless Gets Big Truck Order Abroad

London Firm Orders 250 and 50 Per Week Thereafter—Standard Also Reports Sales

NEW YORK CITY, Dec. 2—It was learned on good authority today that the Peerless Motor Car Co., Cleveland, O., has recently made a sale of 250 trucks in London through Gaston, Williams & Wigmore. The trucks are mostly 4-ton types to be fitted with conventional army body. Besides this initial order of 250 there is an order for fifty a week after this number has been fulfilled for a period until notification terminating such has been given.

It is also understood that the Standard Motor Truck Co., Detroit, has made a large sale of trucks in London and that shipments of these have been in progress for some time.

Four-Cylinder Pratt $1,950

ELKHARDT, IND., Nov. 30—Two new Pratt models will be marketed for 1915 by the Elkhart Carriage Mfg. Co., Elkhart, Ind. One is a four-cylinder Forty selling for $1,950 with five-passenger body and the other is a six-cylinder Fifty priced at $2,150 when equipped with five-passenger body. Four body styles will be offered with each chassis; two, four, five and seven-passenger types.

These cars are made from standard parts throughout. Continental motors with multiple-disk clutch and Brown-Lipe four-speed gearset with direct on third are used. The four-cylinder motor is an L-head design with cylinders 4.125 by 5.25 inches cast in a block. The six has a bore and stroke of 3.75 by 5.25 inches. The cylinders are cast in threes. The electrical system includes a Gray & Davis starting and lighting system and an Atwater Kent ignition outfit. Timken axles are used on all cars.

The equipment includes a one-man top, Collins curtains, Kellogg power tire pump, Troy clear-vision windshield, Jones speedometer, eight-day rim-wind clock, electric horn, nickel-plated bumper of channel steel, etc.

NEW YORK CITY, Dec. 2—Russell T. Kingsford, chief engineer of the Rushmore Dynamo Works of the Bosch Magneto Co., has tendered his resignation to accept a similar position in charge of the private laboratory now being fitted out by S. W. Rushmore, who recently sold the Plainfield works to the Bosch company.

NEW YORK CITY, Dec. 2—The Donnelly Motor Equipment Co., a local corporation dealing in automobile accessories, has made an assignment to Edward J. Walters. It was incorporated in June, 1913, with a capital stock of $5,000, and Richard F. Ely is president.

Engineer Petard Wounded at Meuse

RACINE, WIS., Nov. 28—Capt. Wm. Mitchell Lewis, president of the L. P. C. Motor Co., Racine, Wis., has received a cablegram from Paris that Capt. René Petard, chief engineer and vice-president of the Racine concern, has been seriously wounded in the fighting at Meuse. M. Petard is a captain of engineers in the French army and has taken part in practically all of the heavy fighting since the outbreak of the war. He was with the range-finding corps in the trenches, but is now in the hospital at Cote d'Or, southeast of Paris. Capt. Petard went to Europe last June to test out the Lewis six, but was pressed into service at once and the car commandered for use by staff officials.

S. A. E. Winter Session January 5-7

NEW YORK CITY, Dec. 2—A tentative program for the winter session of the Society of Automobile Engineers has been announced. The meeting will be held in this city Tuesday, Wednesday and Thursday, January 5, 6 and 7. The meeting on Tuesday will be for the standards committee in the morning, governing committees of sections in the afternoon and council in the evening. All members are invited to attend the session of the standards committee. These meetings will be held in the rooms of the society at 1790 Broadway. Thirteen papers and fourteen standards committee division reports will be submitted for discussion.

The remainder of the schedule will be held at the Engineering Societies Building. It is the regular professional session and is made up as follows:

WEDNESDAY, JANUARY 6, 10 A. M.

President's Address.
Treasurer's Report.
Report of Tellers of Election of Officers.
Report of Membership Committee.
New Business.
Report Ball and Roller Bearings Division.
Report Carbureter Fittings Division.

WEDNESDAY, JANUARY 6, 1 P. M.
In the Auditorium, Engineering Societies Building,
(29 West Thirty-ninth Street.)

PROFESSIONAL SESSION

Recording Devices for Commercial Power Wagons.—Bruce Ford.
Report of Truck Standards Division—Wm. P. Kennedy, Chairman.
Report of Commercial Car Wheels Division.—Wm. P. Kennedy, Chairman.
Report of Electric Vehicle Division.—A. J. Slade, Chairman.

INFORMAL DINNER, AT 6.30 P.M.
At the Engineers Club
(32 West Fortieth Street.)

WEDNESDAY, JANUARY 6, 8 P. M.
In the Auditorium, Engineering Societies Building,
(29 West Thirty-ninth Street.)

Pros and Cons of Correct Tire Inflation.—C. B. Whittelsey.
Report of Pleasure Car Wheels Division.—Henry Souther, Chairman.
Wire Wheels versus Wood Wheels.—R. B. Mudge.
Wire Wheels versus Wood Wheels.—Geo. W. Houk.
Report of Lock Washer Division,—J. E. Wilson, Chairman.
Report of Miscellaneous Division.—J. G. Utz, Chairman.

THURSDAY, JANUARY 7, 10 A. M. SHARP
In the Auditorium, Engineering Societies Building,
(29 West Thirty-ninth Street.)

PROFESSIONAL SESSION

Report of Electrical Equipment Division.—A. L. Riker, Chairman.
Railway Gasoline Locomotives.—A. H. Ehle.
Railway Motor Cars.—H. G. Chatain.
Warning Signals.—Alden L. McMurtry.
Report of Research Division.—David L. Gallup, Chairman.

THURSDAY, JANUARY 7, 1 P. M.
In the Auditorium, Engineering Societies Building,
(29 West Thirty-ninth Street.)

PROFESSIONAL SESSION

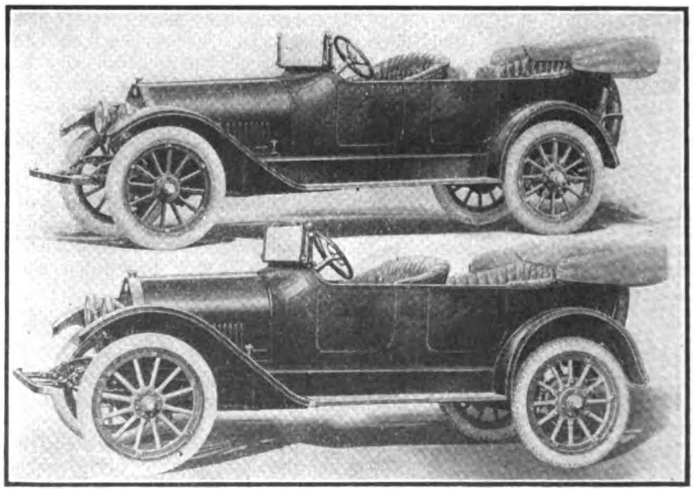
Malleable Iron Castings.—Dr. Richard Moldenke.
Report of Frame Sections Division.—J. G. Perrin, Chairman.
Report of Iron and Steel Division.—Henry Souther, Chairman.
Nomenclature of Car Parts.
Allowances for Piston Fits.—E. W. Weaver.
Worm Gears.—C. T. Myers.

INFORMAL DINNER, AT 6.30 P.M.
At the Engineers Club
(32 West Fortieth Street.)

THURSDAY, JANUARY 7, 8 P. M.
In the Auditorium, Engineering Societies Building,
(29 West Thirty-ninth Street.)

PROFESSIONAL SESSION

Automobile Engineering Curricula.—Prof. W. T. Fishleigh.
Motor Car Testing.—A. B. Browne.
Report of Springs Division.—C. W. McKinley, Chairman.
Report of Standards Exchange Division.—K. W. Zimmerschied, Chairman.
The European Situation as Affecting America.—A. Ludlow Clayden.



Upper—Pratt six-cylinder Fifty selling at $2,150 when equipped with five-passenger body. Four styles are furnished, two, four, five and seven-passenger for both this model and the four-cylinder chassis. Lower—Pratt four-cylinder Forty selling at $1,950 with five-passenger body

To Make Low-Priced Electrics and Trucks

Storms Company Organized to Build Passenger and Delivery Cars Selling at $650 to $950

DETROIT, MICH., Nov. 28—The Storms electric passenger and commercial cars which are to be placed upon the market in January will be made by the Storms Electric Car Co., a new concern, which has just been organized. William E. Storms, formerly with the Anderson Electric Car Co., is the designer and president of the company, Ferdinand H. Zilisch, a business man of Milwaukee, Wis., is vice-president and F. T. King, Detroit, is secretary and treasurer.

One standard chassis will be made by the new company, to take three different bodies, a coupé, a roadster and a delivery body. Wheelbase will be 90 inches and tread 44 inches. completely equipped with electric lights inside and outside, electric horn and other stock equipment, the coupé is to sell at $950, the roadster at $750 and the delivery car at $650. The coupé will be made to seat three persons and the roadster two. The vehicles will be fitted with a specially designed battery which will travel 40 to 50 miles on a single charge. The commercial car will have a body to carry a load of 500 pounds.

Temporarily the headquarters are with F. T. King, 340 Gratiot avenue. Negotiations are now pending concerning a plant.

PLAINFIELD, N. J., Nov. 28—The Spicer Mfg. Co., maker of universal joints in this city, has issued a series of five data sheets for the handbook of the Society of Automobile Engineers. These data sheets give complete illustrations and measurements of the different universal joints manufactured by this company. The illustrations show that only minor details have been made in these joints for 1915, but that radical changes are being made in propeller shafts in motor cars and trucks. The tubular construction has taken hold very strongly as it is lighter and stiffer than the solid shaft, thereby being less susceptible to whipping. With longer propeller shafts due to increased wheelbases in both passenger cars and trucks the time is opportune for greater development in the tubular propeller shaft.

BOSTON, MASS., Nov. 28—Massachusetts motor organizations are now planning a campaign to have the law regarding blowing horns changed so that there will not be such a constant din in the city streets day and night. Under the law the drivers must blow the horn at every cross street where the view is obscured, also to warn pedestrians of danger. Another section states that it must not be sounded so as to make a harsh, and unreasonble noise. But when a driver is in the thickly settled part of the cities he must blow the horn every few feet because of the cross streets.

Goodyear Safety Work Brings Good Results

AKRON, O., Nov. 28—A comprehensive report is being prepared by the Goodyear Tire & Rubber Co., showing the result, at the close of the fiscal year, of the Safety First movement in the factory.

For several years the company has had a safety engineer, whose business it is to install safeguards for machines and make safe places found dangerous. It is interesting to note that when the safety movement was first begun Goodyear factory employes were skeptical and some of them regarded the whole proposition as a joke. But, so greatly have factory accidents been cut down in number that the skepticism is all gone and nearly all of the 7,500 workmen are aiding the movement heartily. They are helped in this by a series of suggestion boxes, in which employes are requested to drop written recommendations, etc., the valuable ideas being rewarded accordingly.

The organization operates as follows: First there is a Central Committee, with the assistant to factory manager as chairman, and a membership of nine men from various parts of the plant who have opportunities for getting about. They report regularly on dangerous conditions found, and each Central Committeeman is chairman of a division inspection committee, so the work is very thorough. One result is that only four out of the 307 men on the committees have been victims, of injury, serious or otherwise.

A new development of the welfare work is a school for foremen,—two lessons a week for 6 months on Organization and Management. Other movements firmly established are lunch room, factory newspaper, library, labor department, hospital and police department, and fine results from all these movements for improving working conditions are reported.

Oldsmobile Co. Advances Pioneer Employees

LANSING, MICH., Nov. 28—Statistics prepared under the direction of D. F. Edwards, comptroller of the Olds Motor Works, reveal that the automobile business holds out assurance of just reward for employees who apply themselves diligently and display intelligence in their work.

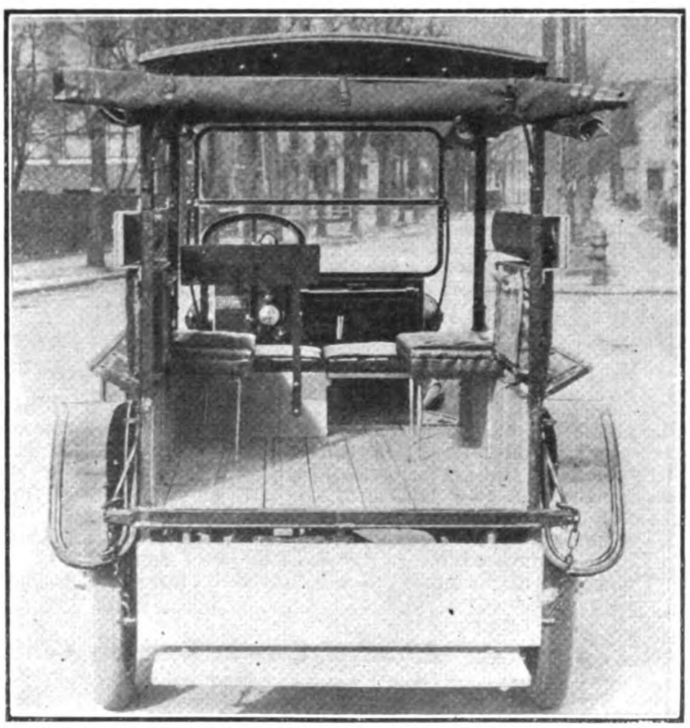
It was shown by Mr. Edwards in the course of his investigation that approximately 30 per cent. of the money paid in salaries and wages by the company since August 1 was paid to employees who had been identified with the company for a period of 3 years or longer.

It was also pointed out that 37 per cent. of the people on its payroll for the period ending October 31 had been in the employ of the company for 3 or more years, and that 30.9 per cent. of its employees had been on the payroll for 5 years or more.

What was even more noteworthy was the fact that 7 per cent. of the employees had been constantly connected for 10 years or longer with this company.

Reasonable remuneration of employees was a point touched upon by Mr. Edwards. To pay in proportion to the worth of an employee and to promote men long identified with the organization in preference to men secured from outside sources is a policy which, Edwards states, has resulted in keeping employees satisfied and living up to their best possibilities.

SPRINGFIELD, ILL., Nov. 28—The officers of the Wilson Tire and Rubber Co. announce that the stock in that concern, which has been selling at a par value of $10 per share, was advanced 25 per cent. on November 24. They state that the factory building in Harvard Park is practically completed, that some of the machinery has already arrived and that much equipment is on the way.



The Studebaker Corp., Detroit, Mich., is now furnishing its dealers with the ten-passenger car of convertible type illustrated above. This vehicle is identical in general construction as far as the chassis is concerned with the four-cylinder delivery car, the only difference being the body. The latter has collapsible seats running lengthwise, and if there are no passengers these seats may be pulled up and the entire body used as a baggage car. Even with all the seats occupied there is still enough room to carry extra luggage

306-Mile Open Race for Oklahoma City

Road Contest for $5,000 Purse Planned for May 1 as Annual Event

OKLAHOMA CITY, OKLA., Nov. 30—A 306-mile road race for a $5,000 purse, to be known as the Southwest Sweepstakes, open to automobiles of every make and horsepower to be held in Oklahoma City May 1 of next year, and annually thereafter is the plan now under way to completion by the Automobile Dealers' Assn., Oklahoma City.

Other purses and other races are being planned by the members of the association to arouse interest in automobile affairs in the southwest. George W. Woods, a publicity agent, conferred with a number of local automobile dealers and the plans for the races are now in progress. Dick Carhart, Overland agent and vice-president of the association, proposes that the event shall be made an annual affair. It is his proposal that the Oklahoma City 26-mile boulevard be linked with a portion of the Gulf-to-Winnipeg road, making a 9.9 mile course for the races.

Surveyors have been employed and are making blueprints of the proposed course which will be submitted to the A. A. A. for approval. It is the plan of those boosting the races that many of the dealers and manufacturers shall be interested in the Oklahoma City race as an opportunity to tune up their cars for the 500-mile Indianapolis race on Decoration Day.

Definite plans have been arranged already, however, for a 99-mile, free-for-all road race for stock cars, to be held here Thursday, April 29, or two days before the proposed Southwest Sweepstakes. To make the races a success an association to be known as the Southwest Racing Assn. is being organized.

To put the course in shape for fast time, the association plans to resurface many of the soft spots at a cost of several thousand dollars, eliminating a few bad turns and banking others, as well as dragging and rolling the entire course. In addition the entire course will be oiled. The automobile clubs of several of the Southwestern states have already written that they would assist.

Race Planned for San Diego, Jan. 9

LOS ANGELES, CAL., Nov. 27—A road race has been projected for San Diego which may take on the color of one of the big speed events of the 1915 season. The date as named by the boosters for the event is January 9, and it is believed that the racers entered at Corona will remain in Southern California for the San Diego event and then go north for the Vanderbilt and Grank Prix races, which are to be held on the exposition course February 22 and 27. The San Diego purse is to come from private individuals. The plan as outlined is for 100 sportsmen to give $100 each, making one of the largest purses ever offered for a motor racing event in the Pacific coast.

Maxwell First Entrant for Indianapolis Race

INDIANAPOLIS, IND., Nov. 28—First entry for the next Indianapolis 500-mile race has already been made, three Maxwells being sent to the post 6 months ahead of the contest. Billy Carlson, the Los Angeles veteran, is the only driver to be named thus far, however, the rest being reserved for choice later on, with Tetzlaff and Oldfield as favorites.

The design of the Maxwells, as last year, is attributable to Ray Harroun, winner of the 1911 500-mile contest.

The piston displacement of the cars falls barely under 300 cubic inches, the limit prescribed by the speedway management. Their bore and stroke is 3 3-4 by 6 3-4, classifying them as of the so-called long-stroke type.

One of the machines will be finished shortly and taken to the speedway for a thorough tryout, lasting a week or 10 days. Harroun himself will conduct these tests.

Originally Harroun planned to produce a double set of cars, reserving one for entry in the French Grand Prix. The European war, however, called a halt to that program.

Hudson 6-54 Wins Harrisburg Economy Run

HARRISBURG, PA., Nov. 26—Eighteen cars were entered in the annual Economy Contest of the Motor Club of Harrisburg held on Thanksgiving Day when the 111-mile run over Pennsylvania hills, a Hudson 6-54 carried off first honors by a narrow margin over a Buick six. A Hudson 6-40 finished third and a Haynes six fourth.

The trip included a route from Harrisburg to Gettysburg, Abbottstown, York, Columbia and Elizabethtown. An average speed of 18 miles an hour was set, but nearly every car made the trip in an average better than 20 miles an hour. The cars were examined, weighed and filled early in the morning by a technical committee under the supervision of Referee W. R. Douglas. Atlantic Refining automobile gasoline of 63-64 gravity was used.

The awards were made according to the weight carried for the gasoline consumed and the heavier loaded cars had something on their lighter rivals. Honors for gasoline consumption went to a little Metz roadster with an average of 32.9 miles to a gallon, but in the touring car class an Overland took first honors with 26.9 miles. The Haynes sixes also made splendid records. Much interest centered in the Cadillac eight, which made an average of 16.9 miles to a gallon. An Autocar truck with passengers also made a successful trip.

The cars that checked at the final control and their records are given in the accompanying table.

Trucks to Be Exhibited at Detroit Automobile Show

DETROIT, MICH., Nov. 30—The annual automobile show of the Detroit Automobile Dealers' Assn. will be held in the plant of the Detroit Lumber Co., West Jefferson avenue, between Campbell and Junction avenues, January 16 to 23.

The building where the show was held in former years was found entirely inadequate for the ever-increasing automobile industry and it was not deemed advisable to take several buildings located far from each other.

The local show will be held in two buildings separated from each other by only 30 feet. The first building from Jefferson avenue, which will be reached from a 100-foot covered walk, is a frame structure one story high, 210 by 136 feet. The trucks, delivery wagons, traction engines, marine motors and motor boats are to be shown there also, and, if possible, the latest Wright biplane. The main building is a three-story concrete structure with two floors 210 by 138 and the third floor 210 by 40. The passenger cars and the accessories are to be shown on the first two floors, all the stands for parts and accessories being against the walls. The third floor will have a café, a cabaret and a dancing pavilion.

One of the features of the show is to be a historical section in the main building where manufacturers will be urged to show their earliest models, either of passenger or of racing cars. Oldfield has promised to have his famous "999" on display and the Winton company is to send its Winton Bullet.

J. C. Ayres, Detroit manager of the General Motors Truck

Scores of Cars in Economy Contest of Harrisburg, Pa., Motor Club

Co., is in charge of the truck section and it is reported that thus far manufacturers of the Buick, Commerce, Federal, General Motors Truck, Packard, Pierce and Standard trucks have applied for space.

Eleven More Exhibitors for Big Shows

NEW YORK CITY, Nov. 28—More accessory exhibitors for the Fifteenth National Automobile Shows in the Grand Central Palace, New York, and the Coliseum and First Regiment Armory, Chicago, next January have been allotted space. During the past week room for the following concerns were found at both shows: Cox Brass Co., Albany, N. Y., and the Standard Roller Bearing Co., Philadelphia, Pa. Additions to the New York show only include the Commercial Lubricating Co., Meadow and Jackson streets, Philadelphia, Pa.; B. W. Spitter, Dorchester, Mass.; Mutual Auto Accessory Co., 58 W. Sixty-fifth street, New York; Zenith Carbureter Co., Detroit, Mich.; New York Sporting Goods Co., 15 Warren street, New York; Dujardin Rubber Co., Brooklyn, N. Y.; Hampton Kerosene Carbureter Co., 1876 Broadway, New York, and Van Norman Machine Tool Co., Springfield, Mass.

There is still some space being made available in Grand Central Palace, New York, but the Chicago buildings are about filled to capacity.

Germany's Export Trade—1912 Foreign Business

(*Continued from page* 1013)

many and one eight from the United States. The statistics for the years from 1909 to 1912 inclusive are:

PASSENGER CARS

	1912	1911	1910	1909
763	$1,663,000	$671,750	$313,000	$35,750

COMMERCIAL VEHICLES

144	411,500	155,000	111,250	48,000
907	$2,077,500	$826,750	$424,250	$83,750

PARTS

...	*$349,250	....	....	....

*Of which $216,750 for automobile tire covers and tubes.

MOTORCYCLES

97	$21,250	$8,000	$6,500	$3,250

British India Important

The British India business is becoming more and more important every year. During the last 7 years ending March 31, 1914, the total value of the cars and parts imported, according to British reports, was $21,055,000 of which $2,-110,000 was credited to the year 1907-1908 and $5,750,000 to the year 1913-1914. Exports from Germany for 1909, 1910, 1911 and 1912 were:

PASSENGER CARS

	1912	1911	1910	1909
48	$83,250	$47,750	$56,000	$20,000

MOTORCYCLES

22	$4 000	$6,250	$3,500	$5,000

PARTS

...	*$312,500	....	....	....

*Including automobile covers and tubes for $176,250.

A $4,275,000 Total

During the 12 months ending March 31, 1914, there were imported a total of 4,419 motor cars and motorcycles, having a total value of $4,275,000, while during the 12 months ending March, 1913, the total was 3,089 cars and motorcycles, having a value of $2,985,000. Out of the 2,880 passenger cars and seventy-six commercial vehicles imported in 1914, 1,669 of the former and forty-two commercial vehicles came from Great Britain, whose share out of the total imports in 1914 was $3,035,000 or three-quarters of the total imports.

The average value of the British car or chassis imported was $1,540, while the average value of the other foreign cars imported was $1,000.

The value of the imports from other countries in 1914 was $370,000 for the United States; $265,000 for Germany; $240,-000 for Belgium; $165,000 for France, and $15,000 for Italy.

Germany's Australasian Share $1,000,000

While total value of the German cars, parts, motor cycles imported into Australasia in 1912 represent a value of a little more than $1,000,000, the total value of these imports from all countries of the world totaled very nearly $9,000,000. The appended chart gives the total value for chassis or complete cars, automobile bodies only, and motorcycles and all parts, either for cars or motorcycles. The total value of imports into Australasia are:

CHASSIS OR COMPLETE CARS

1912	1911	1910	1909	1908
$7,257,475	$5,090,100	$3,471,230	$2,177,570	$1,414,515

BODIES

1,100,440	802,710	480,015	313,210	215,990

MOTORCYCLES AND PARTS

623,270	292,290	229,905	168,290	90,750
$8,981,185	$6,185,090	$4,181,150	$2,659,070	$1,721,255

England has been the biggest supplying country for Australasia. The United States are second on the list, then comes France, Belgium, Italy, Canada, Germany, as far as the imports during the first 6 months of 1912 indicate.

$2,889,620 South Africa's Total

The total value of the automobiles and automobile parts imported into South Africa in 1912 was $2,889,620 of which $1,549,575 is credited to Great Britain, while the United States are next with the total of $720,025. Canada follows with $251,110, then comes Germany with imports totaling $166,960, then France and Italy.

The total value of the motorcycles and motorcycle parts imported in 1912 was $771,180 of which $682,765 is to the credit of the British manufacturers. Germany follows, then France and the United States.

The increase of the automobile imports in 1912 over 1911 represents in value more than $1,000,000 while the motorcycle imports increased by over $400,000.

British consular reports give some interesting data about the imports of chassis and bodies into New Zealand for the years 1910 to 1913 and, while the details per country are not shown, it will allow those interested to get a good idea of the increasing business in that country.

CHASSIS

Year	Number	Total Value	Average Value
1910	772	$900.325	$1,166
1911	1,524	1,581,925	1,030
1912	2.340	2.113 300	903
1913	2,428	2,199,610	906
Total	7,064	$6,795,160	962

BODIES

Year	Number	Total Value	Average Value
1910	726	$206.250	284
1911	1,473	433,625	294
1912	2,265	697,115	307
1913	2,331	712.815	305
Total	6,795	$2,049,805	301

The imports of chassis from the United States increased in value from $96,607 in 1910 to $438,983 in 1911 and to $681,269 in 1912. During those 3 years the imports from Great Britain increased respectively from $126,586 to $905,-692 in 1911 and to $957,097 in 1912. Thus the American business increased nearly $250,000 in 1912 as against an increase of only $50,000 for the British business. The imports of cars and parts from the United States represented nearly one-third out of the total imports in 1912.

Factory Miscellany

WILL Enlarge Hudson Factory—Evidence of satisfactory business conditions is shown by the announcement of additions to be made to the factory of the Hudson Motor Car Co., Detroit. It has, therefore, been decided to add a third story to the main factory building and to three of the largest wings, an addition of floor space 2,200 feet long by 60 feet wide. In construction the addition will conform to the present style of pressed brick and concrete. Work on the additional story will begin at once. It is to be completed on March 1, 1915.

Sevison's $5,000 Fire Loss—The factory of the Sevison Electric Co., Elkhart, Ind., maker of automobile fixtures, suffered $5,000 loss from fire November 17.

Xenia Rubber Adding—The Xenia Rubber Co., Xenia, O., is installing a new mill at its plant on West Main street which will increase the factory of the plant four or five times.

Morrill & Morley Move—The Morrill & Morley Co., Benton Harbor, Mich., manufacturer of automobile parts and spray pumps, has moved into its new plant and is now also making automobile body castings.

Chester Co. to Make Trucks—The Chester County Motor Co., Coatesville, Pa., has increased its captial stock to $500,000 and plans the construction of a factory for the manufacture of commercial trucks. J. Edwin Brinton is president.

Mercury Cyclecars at $200.—The Michigan State Auto School, 11 Selden avenue, Detroit, Mich., which has purchased the Mercury Cyclecar Co., will continue to make the Mercury cyclecars. They will be sold at $200 instead of $375, the old price.

Louisville Co. to Make Inner Tubes—The Southern Rubber Products Co., Louisville, Ky., has been incorporated with $25,000 capital stock by A. F. Wolke and others and will establish a plant for the manufacture of inner tubes for automobiles.

Silver Ray Makes Lamps—The Silver Ray Lamp Co., Cleveland, O., recently incorporated, has leased a two-story building from the Cleveland Fixture Co., 1315 East 40th street, and will install a factory for the manufacture of automobile lamps.

New Truck Factory in Columbus—It is reported that Weller & Thomas have had plans prepared for a motor truck factory, 100 by 190 ft., two stories, of brick construction, to be erected at Columbus, O. J. A. Thomas, 287 Dryden avenue, Zanesville, O., can furnish full particulars.

Stutz Buys Two Lots—The Stutz Motor Car Co., Indianapolis, Ind., has bought two lots adjoining its plant on the north at Tenth street and Capitol avenue, to provide for further expansion. The lots front 100 feet in Capitol avenue and have a depth of 208 feet. The consideration was $10,000.

Ford Plant Ready in January—The Ford Motor Co. expects to have its assembling plant in Atlanta, Ga., now in course of construction at Ponce de Leon avenue and the Southern railway belt line, completed by the middle of January. The Ford people will employ some 200 or 300 men in the new plant and will materially increase the banking business of Atlanta's banks, as well as add the spending capacity of its help to the city's mercantile business.

Gallup in New Tire Co.—E. E. Gallup, of the Gallup Rubber Co., Pittsburgh, Pa., and several associates have arranged for the purchase of a large manufacturing location in the southwest part of Minerva, O. It is the intention of the company to immediately begin the erection of a large rubber and automobile tire plant with a capacity of 500 casings and inner tubes per day, demanding the employment of from 300 to 500 men. The company that will in all probability be incorporated under the laws of Ohio with a capitalization of $200,000, will be named in honor of Minerva as the Minerva Rubber Co.

Maxwell Charters Boat for Shipment—Recently the Maxwell Motor Co., Detroit, Mich., chartered the White Star Line steamer Wauketa to carry fifty Maxwell cars to its Toledo distributors, Landman & Griffith. It is claimed that this is the first time that an entire boat load of automobiles have been shipped by one concern.

Midgley Tires in December—The Midgley Tire & Rubber Co., Lancaster, O., is busily engaged in installing the calender, the last piece of mill machinery to arrive. This piece of machinery is to roll the rubber into strips. The boilers and engine are all ready to run, although several small pipes are yet to be connected. While the plant will likely be running by December 1, no tires will be produced until the 15th, it is believed.

Universal Oxygen Doubling Output—The Universal Oxygen Co., Sheboygan, Wis., which established a plant for the production of gas for concerns operating welding and cutting apparatus about 8 months ago, is preparing to double the output. For 2½ months the plant has been working day, night and Sunday shifts and the monthly production of gas has reached nearly 90,000 cubic feet. This is being shipped in steel drums to all parts of the country. Until recently the supply of containers was derived from Germany, but this has now been stopped by the war and in doubling the size of the gas producers, the company is planning to add a machine shop for the manufacture of drums. About 1,500 German-made drums are now in use. The company operates under the Rowlands-Mueller gas producer patents.

The Automobile Calendar

Dec. 1-4.........New York City, Annual Meeting of the American Society of Mechanical Engineers.

Dec. 12-19.......Akron, O., Show, Akron Auto Show Co., O'Neill Bldg.

Dec. 14-18.......Chicago, Ill., American Good Roads Congress.

Jan. 2-9.........New York City, Annual Automobile Show, Grand Central Palace.

Jan. 2-9.........New York City, Automobile Salon, Grand Ball Room of Astor Hotel, Automobile Importers' Alliance, E. Lascaris, Pres.

Jan. 5-7.........New York City, Engineering Societies' Bldg., Winter Meeting Society of Automobile Engineers.

Jan. 9-16........Philadelphia Show, Metropolitan Bldg., Philadelphia Auto. Trade Assn.

Jan. 16..........Detroit, Mich., Show.

Feb. 23-27.......Syracuse, N. Y., Show, Syracuse Auto Dealers' Assn.; H. T. Gardner, Mgr.

Feb. 27..........San Francisco, Cal., Panama-Pacific Exposition, Grand Prize Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

Mar. 6-13........Boston, Mass., Show, Mechanics Bldg., Boston Auto Dealers Assn., Boston Commercial Motor Veh. Assn.

Mar. 9-15........Des Moines, Ia., Show, C. G. Van Vliet.

Mar. 14..........San Francisco, Cal., Panama-Pacific Cup Race, Panama-Pacific Exposition Grounds; Promoter, Panama-Pacific Exposition Co.

April............Calumet, Mich., Show, Coliseum.

May 29...........Indianapolis, Ind., 500-Mile Race, Indianapolis Motor Speedway.

Sept. 20-25.......San Francisco, Cal., International Engineering Congress.

The Week in  the Industry

Motor Men in New Roles

AUGHE Chalmers Treasurer—H. J. Aughe has been elected treasurer of the Chalmers Motor Co., Detroit, Mich., succeeding C. A. Pfeffer, who was recently appointed assistant general manager.

Mr. Aughe has been associated with the company for the past 6 years and has won his way from the clerical ranks of the treasurer's department to his present position. He was previously general auditor. He assumes the duties of treasurer immediately.

Hopkins Heads Cadillac in Atlanta—Lindsey Hopkins will become on or about December 1 executive head of the Atlanta Cadillac Co., Atlanta, Ga.

Jessup District Sales Manager—C. A. Jessup has been made Southern district sales manager for the Kelly-Springfield Tire Co., with headquarters in Los Angeles, Cal.

Jackson Resigns from Bailey Electric—L. B. Jackson, chief engineer of S. R. Bailey & Co., Inc., Amesbury, Mass., has resigned. His future plans are not definitely decided.

Loomis Heads Southern Motors—G. S. Loomis, formerly department head in the sales division of the Packard Motor Car Co., Detroit, Mich., is now general manager of the Southern Motors Co., Louisville, Ky., one of the most important automobile business concerns in the South and which handles the Packard, Hudson, Dodge gasoline cars and Detroit electrics.

Copley Franklin's Spokane Manager—L. B. Copley arrived in Spokane, Wash., during the past week to take the management of the Franklin Auto Sales Co., distributor of the Franklin car and Kelly-Springfield trucks.

Allyn Tacoma Speedway Pres.—At the annual meeting of the Tacoma Speedway Assn., Tacoma, Wash, Frank Allyn was re-elected president; F. E. Jeffries, vice-president; H. E. O'Neal, treasurer, and George Dunn, secretary.

Harshberger J.-M. Agent—The H. W. Johns-Manville Co. has named Z. F. Harshberger its agent for Indiana, with headquarters in Indianapolis. Under the Indiana law an outside corporation must name an official agent upon whom court papers may be served.

Brown Seattle Firestone Manager—C. W. Brown, for several years a member of the Firestone sales staff in San Francisco and formerly manager of the Oakland branch of the Continental Tire Co., has been named manager of the Seattle branch of the Firestone Tire & Rubber Co., succeeding Ed. L. Campion, who resigned to become sales manager of the Marathon Tire Co.

Lemley Seattle Manager—G. G. Lemley, for 2 years purchasing agent and treasurer of the automobile and accessory firm of Ballou & Wright, has been named manager of the Seattle, Wash., store of the company, succeeding A. H. Jones, who has retired to devote his time to developing a new non-skid tire.

Jack's Former Position—It was stated in these columns last week that R. F. Jack, formerly assistant chief engineer of the Cadillac Motor Car Co., Detroit, had been appointed chief engineer of the Russell Motor Car Co., Ltd., Toronto, Ont. The name should have been R. K. Jack and his former position was assistant to the Cadillac chassis engineer, Mr. Snell.

Bauer Edison's Chicago Manager—F. Bauer has been appointed manager of the Chicago office, Edison Storage Battery Co., Orange, N. J., succeeding C. B. Frayer, who retired November 30 to devote himself to private interests. Mr. Bauer has been with the Edison company about a year as assistant manager of the railway department. He is president of the Railway Electrical Supply Manufacturers Assn., an organization in which he has been active since its formation.

Recent Incorporations in the Automobile Field

Canada

QUEBEC—Safety Tire Co.; capital, $1,000,000; to manufacture wheels, rims, tires, etc. Incorporators: Joseph G. Frenette, Arthur Moisan, Ernest Taschereau and others.

SUMMERSIDE, P. E. I.—Canadian Auto-Pneumatic Pump & Machinery Co.; capital, $35,000. Incorporators: J. A. Van Tilburg, F. A. Johnson and D. A. Pickering.

TORONTO, ONT.—Anglo-Canadian Motor Sales Co.; capital, $50,000; to manufacture and deal in automobiles. Incorporators: A. G. Browning, A. Fry, G. E. Buchanan, all of Toronto.

Connecticut

STAMFORD—Motor Sales Co.; capital, $50,000. Incorporators: Allen Selden, A. K. Shaw and Floyd Bartram, all of Stamford.

WATERBURY—International Top Co.; capital, $100,000; to manufacture automobile tops. Incorporators: W. R. Upson, A. W. Chenoweth, G. W. Seaton.

Delaware

WILMINGTON—Pneumatic-Hub-Tire-Wheel Co.; capital, $500,000; to manufacture motor car wheels and tires. Incorporators: G. J. Lampton, N. M. Rowland and L. C. Evans, all of Louisville, Ky.

Illinois

CASEY—K. L. Mfg. Co.; capital, $100,000; to manufacture gasolene dispensers. Incorporators: W. B. Linn, C. E. Bennett and J. H. Barker, all of Casey.

CHICAGO—Advance Garage Co.; capital, $2,500; to manufacture and deal in, store and repair motor vehicles. Incorporators: Samuel Topliff, Sigrid Erickson and Homer H. Cooper.

CHICAGO—Automobile Securities Co.; capital, $2,500; to deal in, repair and rebuild motor cars, parts and accessories. Incorporators: H. T. Potter, K. M. Lorenz and L. I. Bretz.

LIBERTYVILLE—Maher Mfg. Co.; capital, $50,000; to manufacture and deal in motor car accessories, lighting fixtures, etc. Incorporators: Nathan L. Maher, Lucas W. Maher and Elton C. Armitage.

Indiana

SOUTH BEND—Standard Auto Supply Co.; capital, $10,000; motor car supplies. Incorporators: Ignatius K. Werwinski, James E. Scott, Joseph Kish, Jr., Julius Fodar and Charles Jones.

SOUTH BEND—South Bend Garage Co.; capital, $5,000. Incorporators: A. D. Parker, G. W. DeClements, D. C. Rogers.

Kentucky

LOUISVILLE—Falls City Auto Co.; capital, $6,000; to supply automobile hearses and carriages for funerals. Incorporators: E. C. Pearson, S. J. McElliott, John Schlidt, Henry Bosse, L. E. Cralle.

PADUCAH—Baker Auto Co.; capital, $5,000; to deal in automobiles. Incorporators: C. N. Baker, E. M. Baker, E. H. Boss.

Massachusetts

BOSTON—Needham Tire Co.; capital, $350,000; to manufacture automobile tires. Incorporators: J. S. Patterson, and others.

Michigan

DETROIT—Electric Welder Co.; capital, $50,000. Incorporators: A. W. Mairs, William F. Schultz, A. F. Sellers and E. A. Buckman.

DETROIT—Michigan Storage Battery Co.; capital, $50,000; to manufacture storage batteries. Incorporators: L. C. and S. G. Knop, N. T. Lawson.

DETROIT—Park Motor Works; capital, $5,000. Incorporators: George Gilmore, Clarence G. Hill and Agnes Callahan.

DETROIT—Rob Roy Mfg. Co.; capital, $20,000; to manufacture motor car parts. Incorporators: Robert Wachman, A. Leroy May, Harry Katz, Gilbert Holmwood, Henry Platz and William E. Burns.

DETROIT—Wolverine Motor Specialty Co.; capital, $1,000; to deal in motor car supplies. Incorporators: Ada S. and Roy W. Kumler and Chas. R. Robertson.

SAGINAW—Letts Auto & Taxi Co.; capital, $7,500; general motor vehicle business. Incorporators: William F. and Charlena D. Letts.

Minnesota

MINNEAPOLIS—Brasie Motor Car Sales Co.; capital, $50,000; deal in automobiles. Incorporators: C. H. Walker, Ole Martinson, Oscar Hellum.

MINNEAPOLIS—Hartsough Tractor Co.; capital, $1,000,000; to manufacture the Lion tractor, a new two-wheel engine invented by D. M. Hartsough.

MINNEAPOLIS—Jackson Motor Co.; capital, $15,000; to deal in automobiles. Incorporators: Fred Darling, N. S. Davis, A. A. Wilson.

MINNEAPOLIS—Simplex Tractor Co.; capital, $250,000; to manufacture tractors. Incorporators: J. W. Muir, G. H. Wilson, C. E. Cottrell, H. J. Hollister.

MINNEAPOLIS—Young Motor Sales Co.; capital $50,000; deal in automobiles. Incorporators: E. N. Young, H. J. Murphy, F. N. Furber.

Missouri

ST. LOUIS—East Side Motor Truck, Transfer & Baggage Co.; capital, $2,000. Incorporators: A. O. Middleton, E. K. Brown and John O. Schwaner.

ST. LOUIS—More Automobile Co.; capital, $15,000; to manufacture, sell, deal in and repair motor cars and accessories. Incorporators: Edward A. More, John B. Strauch, John T. Salisbury and Cyrus B. More.

North Dakota

BISMARCK—Missouri Valley Motor Co.; capital, $25,000; general motor vehicle business. Incorporators: Louis A. Tavis and Joseph P. Hess, both of Mandan; Howard H. Moore, Minneapolis, Minn.

WILLISTON—Williston Motor Co.; capital, $25,000; to deal in motor cars. Incorporators: C. A. McKinney, F. N. Fuller and M. L. McKinney, all of Williston.

New York

BROOKLYN—Hanson Peacock Corporation: capital, $1,000; to manufacture motors, tires, etc. Incorporators: Joseph L. Young, 209 Adelphi street; Selma Hietenstein, 841 Beck street; E. Katherine Payne, 430 Main street, New Rochelle.

BROOKLYN—Overfield Auto Co.; capital, $1,000; to deal in motor cars. Incorporators: Ferris A. Overfield and Eda D. Overfield, both of 204 Sunnyside avenue; George S. Hice, 43 Jerome street.

BROOKLYN—Arthur R. Tator Co.; capital, $1,000; to deal in motor cars, tires, etc. Incorporators: Arthur R. Tator, 1051 Prospect place; Hugh Foster 617 McDonough street; John F. Undutsch, 1051 Halsey street.

BUFFALO—Western Sales Corporation; capital, $15,000; to manufacture and deal in tire fillers, motor car accessories, etc. Incorporators: Charles H. Taylor, Thomas Catlin and Sherman A. Hooker, all of 1330 Marine Bank building.

NEW YORK—Fireproof Garage Co.; capital, $5,000; to operate a garage. Incorporators: James R. Pierson and Samuel Riger, both of 29 Broadway; Thomas McD. Caffrey, Hohokus, N. J.

NEW YORK—Globe Garage Co.; capital, $3,000; to operate a garage. Incorporators: Philip Lauter, 813 E. 163rd street; Ignatz Lauter, 152 W. 90th street; Morris M. Gruber, 800 E. 168th street.
